At the same time, we had several of these rambling Roses, which were to be admired for their vigorous constitutions as well as for their foliage and flowers, which were of "rampant" growth, mounting our walls almost as rapidly as Jack on his Beanstalk, and defying our thunderstorms, fogs, and frosts. These were the Ayrshire and Sempervirens, with their glossy and pretty clusters of buds and flowers: the Noisette, Aimée Vibert, "clad in robes of virgin white"; the fragrant pale yellow Lamarque, beautiful in health, but liable to catch cold and to succumb to a chill if misplaced in exposed situations; and Solfaterre, with its large golden yellow flowers demanding and deserving a congenial site, a fertile soil, and the gardener's generous care. The Bour-sault Roses, Amadis (dark crimson), and Gracilis (bright rose), were robust in growth and effective (at a distance), although the flowers were of brief duration; but the most successful of all, though the success was only known to the few who stole from Pomona the mural space which is usually regarded as her right were certain varieties of the Hybrid Bourbon and Hybrid China section. They are summer Roses, and make no claim, like the Roses of Pæstum, to an autumnal bloom (there are many Hybrid Perpetuals who promise but do not produce it, as the cricketer who makes a century in his first innings and a duck's egg in his second), but that bloom is of long duration and of transcendent beauty. What can be more lovely than a tree of Blairii 2, 10 feet in height and 20 feet in breadth, with its infinite abundance of blush Roses, so full and yet so perfect in form. Charles Lawson and Paul Ricant of the same family are also magnificent on a wall, and I shall never forget a grand specimen of Paul Perras which I saw many years ago on the rectory at Drayton, near Norwich, the home of a beloved friend.

Here and there upon ancient mansions, where they were screened from the violence of the storm but enjoyed the warmth of the morning and midday sun, Tea Roses were to be found with their shining foliage, pretty

white buds, and faint odour, having no special designation, but commonly known as Odoratas, and generally supposed to have been brought home from India or China by nautical ancestors who had been famous travellers, or who had fought for their country on the high seas.

Then came in 1853, *annus mirabilis*, a jubilee year in the reign of the queen of flowers, ever to be remembered for the arrival at her court of a new lady-in-waiting, who was to win all hearts, wherever she went, by her beauty and gracious demeanour. She bore an illustrious title as Gloire de Dijon, and was preceded by grandiloquent descriptions of her charms; but we had become suspicious and sceptical from disappointments previously inflicted upon us by "our lively neighbour the Gaul," by our inability to verify his effusive epithets of *magnifique, séduisante, parfaite, superbe*, and we read with incredulous derision that this new *débutante* combined every excellence of flower, foliage, colour, form, and fragrance, with the most vigorous growth and the most abundant bloom. We were speedily convinced that the portrait of gaudy colours did no justice to the reality. It was, and it is, the first and the last of our outdoor Roses to gladden our eyes in May and in December. It has a variety of tints which we find in no other Rose, white and red, orange, lemon, and buff. It flourishes anywhere, everywhere, where there is purity of air and depth of soil. It beautifies castle and cottage, through the length and breadth of the land. Gloire de Dijon is a Gloire d'Angleterre.

It adapts itself to a large or to a limited space. It has prospered for forty-four years upon the chancel of Cauntton Church, and I have counted more than 300 Roses in simultaneous bloom; and I shall never forget a pathetic incident when, returning from a vain search in Brighton Cemetery for the resting-place of one very dear to me, I saw a Rose in the middle of the ground, the only one visible, for it was in the beginning of winter, and I drew near it to find Gloire de Dijon planted by the grave of my friend!

The distinguished foreigner was followed, like other successful immigrants, by her relations, notably by her beautiful sisters Mme. Bérard and Reine Marie Henriette, with others bearing a strong family likeness; but they paled their ineffectual fire in her presence like glow-worms at break of day.

A decade passed before another record Rose appeared among the climbing varieties, and brought to us rosarians the most joyful surprise and excitement within the range of my experience. Long time we had sighed and hoped for a grand yellow Rose; we had abandoned Cloth of Gold in despair; the Banksian flowers were too sparse, too small, and too pale; we were thankful admirers of the Austrian Briars Harrisonii and Persian Yellow, but they did not satisfy; we envied Mr. Gilbert, at Burghley, his splendid double yellow Provence, which we failed to grow, as our ancestors, who were ever enquiring "how to blow the yellow Provence Rose?" had failed. We put the hard, constipated buds of Smith's Yellow into warm water, and tried with all the breath at our disposal to bid them come forth and suffer themselves to be admired; but all our efforts, all our aspirations, were in vain. Suddenly, as to one who dreams that he is imprisoned in a dark dungeon for life, and wakes in sunshine, we had before us our heart's desire, Maréchal Niel, in all his golden glory! It could not achieve the popularity, because it had not the hardihood, of Gloire de Dijon; but it is a priceless jewel in Queen Rosa's

crown, and it is much hardier than many suppose. By far the best specimens I have grown were upon a wall here (Cauntton) with an east aspect, and I have two trees now bearing beautiful blooms which have been for more than twenty years in the same position. They are sometimes severely punished in the winter, but they revive in spring and flower in the summer. Sometimes they perish, but

"Tis better to have loved and lost
Than never to have loved at all."

(To be continued.)

GARDENING OF THE WEEK.

FLOWER GARDEN.

THE ROCK GARDEN.

AFTER heavy rains it is advisable to go over the rock garden and replace with fresh soil any that may have been washed away. In such places a few pieces of slate or flat stone placed edgways at fairly close intervals will prevent much of the washing, and not be at all conspicuous. Any plants which are battered by rain and winds must receive attention in the shape of removing the worst leaves, cleaning the remainder, and carefully tying the growths into shape.

It is wise to be on the safe side and insert a few cuttings of any tender Saxifrages, Sempervivums, and other plants of doubtful hardiness. These placed in a cool frame will soon root in sandy soil. Small pieces with a few roots attached may be easily removed from many plants. These potted into small, well drained pots will quickly become established and be fit for planting out next spring. In the case of single specimens of valuable alpine it is, perhaps, as well to pot them up, and also winter them in cold frames, and next year with increased strength they may be left out. On the first dry, sunny day, all the remaining ripe seed should be gathered. The cleaning and packeting of these will furnish employment for a wet day.

HARDY CACTI.

This interesting class should receive especial attention just now, so that they may be in the best of condition to withstand the autumn rains and damp, muggy days. The portable lights should be thoroughly overhauled to see that the glazing is water-tight, and, of course, any broken or cracked squares of glass should be repaired. A coat of paint will improve their appearance and preserve the woodwork. If at all close or mossy, the surface soil should be removed, replacing it with fresh, in which broken sandstone and grit largely predominate. All decaying portions should be removed with a clean cut of a sharp knife. Pieces of charcoal and freshly-broken sandstone placed around the stems will absorb a deal of moisture, and help to keep the roots in that state of comparative dryness which is so essential to their well-being for some months onwards. Here, again, it is advisable to insert a few cuttings, and winter them under warmer conditions. When the weather requires the plants to be protected by the lights, care must be taken to ventilate freely whenever possible.

LATE-FLOWERING TULIPS.

As most of the species, Darwin, Parrot, Cottage, and other late-flowering sorts, require a longer period of growth than the more common Dutch breeders, they should now be planted. The home-grown bulbs require cleaning and sorting; any outer scales which are not perfectly healthy must be rubbed off. The smaller bulbs should be kept for the reserve garden and out of the way corners. Plant rather more closely than with the Dutch bulbs; the depth will vary with the texture of the soil. Where it is heavy 4 inches will suffice, and in a light soil a couple of inches should be added. Many of these late Tulips flower well in partial shade, in such a place as is suitable for the smaller Fritillarias, which are also among subjects for present planting.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

TREE CARNATIONS.

THOSE that have formed their flower-buds early should now be taken under shelter; indeed, they should be placed where they are to flower during the autumn. The plants as they are being taken inside should have a good stake placed to each, and the shoots, as well as the flower-stems, be made secure. Remove from the surface soil in the pots any weeds or moss that may have accumulated. Although the plants appear to have made good roots, stimulants are not at present necessary, except that a dose or two of weak soot water may be given with a view to sustaining them in a healthy condition. A great enemy is greenfly, from the ravages of which the plants may be easily freed by syringing with well diluted nicotine, as well as fumigating occasionally with XL All Vapouriser.

INDIAN AZALEAS.

Most of these by this time have set their flower-buds, and have ripened well their growth. They will be quite ready for being taken inside, and they will be safe against heavy rains, as well as from injury by early frost. There is no better season for overhauling the collection and for repotting those that require more space for their roots than the present, and the compost for the latter purpose should consist of two-thirds good fibry peat to one of good loam, grit, and sand. Syringe the plants well with insecticide before they are housed, and afterwards fumigate well with XL All to entirely eradicate any thrips with which they may be infested. For some time yet the ventilators may be kept open night and day, and keep the surroundings of the plants healthy by syringing the stages and paths two or three times a day. Although the supply of water to the roots of these plants should gradually diminish, they must never be allowed to suffer from lack of moisture.

COLEUSES.

The simplest way of maintaining a stock of these through the winter is to put from three to five cuttings in a 4-inch pot and root them in bottom-heat at once. Directly they have rooted nip out the lead, encourage them to break, and then place them near the glass in any house where the temperature ranges from 55° to 60°, and where on all favourable occasions a little fresh air can be admitted. Immediately a sufficient stock of cuttings is obtained use the old plants for any decorative purpose, as afterwards they can be thrown away to economise space.

MARGUERITES.

The young plants which are expected to flower early next season should be propagated from cuttings to be inserted at once. For the purpose select good strong half-ripened shoots, and insert these in sandy soil about three to five around the sides of 4-inch pots, and place in any close position with shade from strong sunshine and they will soon emit roots. They will not require separating until the spring of next year, but should be given abundance of air and light during the winter months.

RICHARDIA ELLIOTTIANA, unlike *athiopica*, requires to be dried off during the winter. For the purpose remove the plants to where they will be quite dry and free from injury by frost. They must not be put under the drip from other plants, and a temperature of 50° will suit them admirably.

Tranby Croft, Hull.

J. P. LEADBETTER.

FRUIT GARDEN.

PINES.

LATE QUEENS which are now swelling their fruit will require more careful treatment as the fruits approach ripeness. They must not be allowed to become too dry or they shrivel. On the other hand, if they get too wet they will turn black in the centre. Clear water only should be given at this stage, and less syringing will be necessary as the days shorten and the sun loses its power.

Keep a night temperature of 80°, falling to 75° in the morning, and a moderately moist atmosphere by sprinkling the beds and damping the paths. During the time the winter fruifers of Smooth Cayennes are in flower the atmosphere should be kept slightly drier, but when they have passed this stage the moisture should be increased, the beds and house generally damped down and closed early on bright afternoons. Weak applications of guano water should be given at alternate waterings. Keep the bottom-heat steady at about 85°, with a night temperature of 68° to 70°, with the usual rise with sun-heat during the day, and admit a little air early in the day before the temperature rises too much.

The earliest successions which are intended for starting early will soon have finished their growth: gradually withhold water from them to induce them to rest. Gradually lower the temperature and give a freer circulation of air on all favourable occasions. Care must, however, be taken that the plants do not become too dry or they will be permanently injured. Overhead syringing should be discontinued, damping of the beds and paths being sufficient at this season, with a night temperature of 65°. Late Queens should be encouraged to make growth some time longer, until the pots are

and burnt ash, with a sprinkling of bone-meal, when the plants are finally potted. Stake the plants and pinch out all side laterals as they appear.

POT VINES.

Pot Vines intended for starting early in November will now have matured their growth and be resting. Very little water will be required when the flowers are ripe. They must not, however, be allowed to become too dry. If the roof lights cannot be removed now is a good time to put the Vines outside. A wall facing south is a good position for them. Make the canes secure to prevent damage from strong winds. Pack up the pots with some material to keep off the sun, and remove all the laterals, as soon as the leaves have fallen. Remove young planting canes as soon as ready to a similar position to become hardened and well ripened.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

CLEANING, &c.

In the north we are at this date (August 30) enjoying a spell of splendid weather with very strong sunshine. Every effort should be made to give the kitchen

THE ARUM LILY BY A DEVONSHIRE POND EDGE. (See page 174.)

well filled with roots and the growths finished for the season. Give weak guano water and soot water at alternate waterings, closing early with sun-heat, until the plants require to be rested as for the earliest Queens. Look carefully after the younger stock, and give them similar treatment as for successions, slightly dewing the plants overhead on bright days only, and gradually reducing the shading as much as possible. Put in any suckers still required at once, to give them time to become rooted before winter. Strong suckers require a 7-inch pot, and smaller ones a 6-inch pot. Pot firmly and plunge in a bottom-heat of 85° to 90°, keeping them as close to the glass as possible. No water will be necessary until rooted through, and watered afterwards only when they require it. Keep the house close, and dew the plants lightly overhead on bright days only, gradually increasing the air as the plants get established.

TOMATOES.

Plants which are required for winter fruiting should be potted on as they require it, and encouraged to make sturdy growth by having plenty of ventilation. The plants do best in a cool pit, and stand them on a firm ash bottom, giving them plenty of room. Use good fibrous loam, lime rubble,

garden a thorough cleaning, and if well done on this occasion it should be the last required for the season. All plots should be gone over and the largest of the weeds pulled out by hand, and afterwards the ground should be given a deep hoeing. Weeds will not make so much progress after this date. Remove all loose and yellow leaves from Cabbages, Cauliflowers, &c., and wheel from the garden. The walks should also be carefully hoed, and, what is more important, carefully raked, as weeds are liable to take root again at this season. Remove Pea haulms that are exhausted. The kitchen garden ought to look well at this date, and cleanliness is the chief factor in bringing about this desirable result.

This is a most suitable time for a consideration of what is to be done by way of improvement in the kitchen garden next year. Crops that have failed will, perhaps, require different treatment or change of ground. Varieties of Peas, &c., that may not have been a success should be noted for discarding. If there has been a gap in the supply a change of varieties will have to be made. Notes should be taken of all vegetables that have not been satisfactory, and plans made to secure success next year. Attention must be given to setting the forcing conveniences into order for the winter's work. The

LOWER SLOPES OF LEBANON COVERED WITH
"SNOBA" PINES.

lifting of Sea Kale, Rhubarb, Mint, &c., will soon have to be done. Manure should be prepared for all plots as soon as possible. Winter Onions, Spinach, and Lettuce should be sown at once to ensure a good growth before frost comes.

TOMATOES.

During this fine weather every effort should be made to get the entire crop ripened, as the hours of sunlight are becoming shorter. All new growth should be kept off the plants, and the fruit turned if possible to the sun. If no leaves have till now been cut from the plants, they may be considerably shortened near the fruit clusters. Plants out of doors should receive similar treatment. If glass lights can be placed in front of the plants it will hasten ripening considerably. After this date frost may occur at night, and a few mats may be held in readiness for covering. Fruits showing signs of ripening should be removed and placed in a warm house to ripen. The flavour may not be of the best, but they will be useful for many purposes in the kitchen. Plants for early winter-fruiting should now have fruit set, or at least be showing flower. Slight stimulants may be given at this stage, and the plants taken indoors to a cool airy house.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE LEBANON CEDARS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have been greatly interested in reading the article in *THE GARDEN* (August 20, page 125) on the Cedars of Lebanon. I have recently visited the Lebanon, and had an opportunity of seeing some of these noble trees in their native habitat. The trees mentioned in your article and described by other travellers are evidently those on the Tripoli range, which is about three days' journey from the Baruk range, which I visited. There appear to be only a few survivors in the former, whereas on the Baruk they number thousands, scattered in various groups, and ranging from a few veterans to many trees in their prime, and quantities of comparatively young ones. Besides these, there are many low stunted bushes only a few feet high, yet evidently many years old, but kept in their dwarf condition by the browsing of goats. If it were not for the depredations of these animals there would soon be hundreds of acres of Cedar forests, as the trees cone freely and shed widely fully-developed seed, and thousands of seedlings can be seen springing up in all directions, but only to be devoured by the herds of goats. An enterprising government would preserve such a fine natural product, and thereby not only

restore a most valuable commodity, but also greatly help to bring a rainfall that would mean fertility to thousands of acres of barren land. I enclose some photographs that I took showing some of the groups with trees of various ages, one of them a stunted tree eaten by goats. The view of the summit shows the snow still lying thickly in patches, and a considerable quantity still remained amongst the Cedars at the time of my visit, so that they literally drank up the snow-water with their roots. But the hot wind and the brilliant sunshine that we experienced would in the course of a few weeks melt the snow.

Longfield Nurseries, Crawley. JOSEPH CREAL.

PHLOXES ON NORTH BORDERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In my remembrance Phloxes have never before suffered so intensely from the heat and drought. With me the trusses did not nearly reach their full size, quite half of the blooms failing to expand. Instead of being in full bloom in the middle of August, by that time the plants had a most wretched appearance, many of the blooms being shrivelled. To such an extent did heat and drought affect the plants that they could not preserve sufficient energy to expand their blooms, a large quantity of the buds withering up. Naturally, when watering with the hose was practicable, Phloxes have been satisfactory, but in the generality of gardens press of work or shortage of

YOUNG CEDARS ON THE SLOPES OF LEBANON.

water rendered such attention impossible. In striking contrast are some plants that are sheltered from the great heat of the sun by evergreens. Although the trusses are not so large as they would have been in a moister season, they are perfect, and look fresh and bright when those in the open are over. By planting a portion of the stock in a north aspect the flowering season is prolonged quite three weeks.

R.

[This Rose was sent out by the late M. Ducher of Lyons, having been first distributed in 1871.—*Ed.*]

LILIES ALL THE YEAR ROUND.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—A decade since it would have been considered impossible even in such an extensive genus as that of *Lilium* to keep up a succession of flowers (of some species or other) throughout the year, the most critical time being after the late summer and

early autumn flowering *L. speciosum* had passed away till the Bermuda-grown *L. Harrisii* unfolded its blossoms. True, one species, *L. neilgherrense*, was at its best anywhere from Michaelmas to Christmas, but then it was always, and still is, a comparatively rare Lily, and invariably realised high prices.

Prior to the early eighties the only attempt at lengthening the Lily season was to grow *L. longiflorum* (usually obtained from Holland) in the greenhouse in order to get the flowers early, and to keep *L. speciosum* out of the ground longer than usual before potting, and then grow them under a north wall, or in some similar position, in order to induce them to bloom late. A little over twenty years ago attention was first directed to the *Lilium* sent here from Bermuda under the name of *L. Harrisii*, which had already made a reputation in America. Among other points claimed for it at first were, that as a species it was perfectly distinct from *L. longiflorum*, that it produced quite a secondary crop of blossoms, and it could be had in flower at a season when we had never before seen *L. longiflorum* in bloom. Time has, however, considerably modified these assertions, for it is now conclusively proved that this Lily is nothing but the variety *eximium* or *Wilsoni* that we get in such numbers from Japan, the difference in the seasons being caused by the climatic conditions of Bermuda, which enable the cultivators to send dormant, well-ripened bulbs that reach here about the end of July or in early August, some two or three months before the Japanese ones arrive. The assertion concerning the secondary display of blossoms is proved to be perfectly correct; but as a set-off to this is the fact that the flowers are so few in number as to be scarcely worth considering. One thing still remains unquestioned, and that is the great value of *L. Harrisii* for flowering quite early in the year, as the bulbs are on receipt quite ready to start, and if potted and placed in a greenhouse or cold frame they quickly root and soon commence to grow. A good light position with a free circulation of air is very necessary, otherwise the stems grow up weak, and a sharp look-out must be kept in all stages for aphides. Beside the name of *L. Harrisii* this Lily in the height of its popularity was sometimes known as *L. longiflorum floribundum*.

After standing out by themselves for some years, these Bermuda-grown bulbs met with a decided set-back, for the experiment was tried of retarding bulbs of various Lilies by keeping them in refrigerators till long past their normal season for starting into growth, and the results proved so satisfactory that large structures have been built for the sole purpose of retarding plants of different kinds for not only Lilies, but *Spiræas*, *Azalea mollis*, *Lilacs*, *Lily of the Valley*, and other subjects have been so treated in a perfectly satisfactory manner. These retarded Lilies consist for

CEDARS ON LEBANON, SHOWING A STUNTED BUSH
IN FOREGROUND EATEN DOWN BY GOATS.

the most part of *L. longiflorum* and *L. speciosum* in variety, but the same principle has been brought to bear on others, particularly *L. auratum* and *L. tigrinum*. The principal consideration in their culture is to allow them to start naturally into growth, for if potted, say, at midsummer, or even two months later, the outside air will, of course, be quite warm enough for them, especially after their icy period, and any attempt to rush matters by forcing will only end in failure.

The best treatment for them is on receipt to place them in a cool shed or similar position for two or three days to make sure that they are thoroughly thawed. Then pot and place in a frame or cool greenhouse, keeping them shaded from the direct action of the sun's rays till the stems appear above ground. When the autumn nights get cool and damp a little fire-heat will of course be needed. An autumn and winter temperature of 50° to 60° is necessary. Generally speaking, *L. auratum* and *L. longiflorum* flower in fourteen or fifteen weeks after potting, and *L. speciosum* and *L. tigrinum* in eighteen to twenty weeks if potted in May, June, or July, and after that a little longer. Nearly all Lily bulbs subjected to the retarding process are imported from Japan, and it yet remains to be seen what effect the regrettable war, now in full blast, will have on the large importations that we annually receive from that country. Grown naturally in the open air the Lily season extends over a lengthened period, though the exact time depends upon the season and locality. Thus, before May has left us we may reasonably hope for the earliest blossoms of *L. bulbiferum*, *L. dahuricum*, *L. elegans*, *L. pomponium*, *L. pyrenaicum*, and *L. rubellum*, followed in June and in July by a much larger number, while August sees *L. auratum*, *L. chalcidonicum*, *L. elegans venustum*, *L. Henryi*, *L. superbum*, and *L. tigrinum*. As a rule the outdoor Lily season ends with *L. speciosum*, represented by numerous forms, and Japanese grown bulbs of *L. tigrinum Fortunei*. T.

INSECT FRIENDS.

ICHNEUMON FLIES.

ICHNEUMON FLIES and their near relatives usually lay their eggs in the bodies of caterpillars, grubs, and aphides, but some species deposit their eggs in chrysalides and in the eggs. These insects, though called ichneumon flies, do not in any way belong to the order of flies proper, which are two-winged insects, but they are classed in the same order as the saw flies, ants, bees, and wasps, and, like them, have four wings. They are nearly all slender in form, and have long legs—the upper pair of wings being considerably larger than the lower pair—whilst the end of the body in the females is furnished with a long pointed organ, known as an ovipositor. In some species this organ is of great length, being longer than the rest of the insect, and enables the possessor to reach its victim, which may be a wood-boring grub, or so placed that it would be inaccessible to the insect otherwise. In other species it is quite short, and may be entirely hidden in the body of the insect when not in use. The ichneumon flies do not try to kill their victims by piercing them with their ovipositors; their only desire is to lay their eggs within them. As soon as the grubs are hatched they begin to feed on the juices of their host. Caterpillars attacked by these parasites live and feed for some time, and have been known to become chrysalides, but this effort on their part is generally more than they can manage. Several of the smaller species attack various kinds of aphides. One may often see on plants a large brown aphid with a swollen rounded body—the result of infestation by one of these parasitic insects; the latter vary much in size, from insects somewhat larger than those shown in the figure to others about the size of a midge. They are generally black-brown or some dull colour, though some have a bright band across the body.

THE FRUIT GARDEN.

VALUABLE LATE CHERRIES.

THIS has been an unfavourable season for Cherries on open walls, and the crops on standard trees in the open in most parts of the country have been very poor. In private gardens few fruits are more valuable, as they come in early, and where there is space to grow a goodly number of trees the supply may be maintained for quite three months. I do not think we pay sufficient attention to the Cherry as regards its culture under glass either as an orchard tree in pots or planted out: the latter is well worth a trial when a house or a portion of the back wall can be utilised. The fruits are large and the flavour better than those grown in the open, and what makes Cherry culture so interesting is that little forcing is required. The culture is simple providing there are ample supplies of moisture and efficient ventilation. Pot trees have found more favour of late years; Messrs. Rivers' exhibits of these trees have proved what good results may be secured with quite small pots.

ICHNEUMON FLIES.

More interest should be taken in this branch of horticulture, as I fail to see when glass is provided so largely for other fruits why the Cherry should be neglected. Two sets of trees may be grown, some being forced, whilst others are plunged outside waiting, and after the fruits have been picked the house may be used for a time for other purposes. By growing Cherries under glass there is greater certainty of a crop, and the trees can be kept cleaner. One of the greatest difficulties of the fruit grower in light gravelly soil is that the new wood of the Cherry is so subject to aphid, and the attacks are persistent.

For late supplies we have trees on east, west, and north walls. Those on a west are quite late. Late Duke is grown, but this variety, though valuable in this respect, lacks the rich flavour of the Emperor Francis, which is a valuable Cherry, and as it does well on a north wall I place it in the front rank for late supplies. In addition to its lateness it is a splendid fruit, a dark red of the Bigarreau section, and a better grower than some of the Duke section. On a north wall it sets later and escapes spring frosts. This variety is not so well known as it should be, and every season we find it more useful. It lasts well into August when grown as described. I have referred to Late Duke, also known under the name of Ronald's Duke. The value of this Cherry is that it hangs so well even when quite ripe, and will give a supply in the northern part of the kingdom well into September; the fruits are large, bright red in colour, and the tree grows freely in soils not of the best kind, so that it is worth room in all gardens where a long supply is required. Our next best late Cherry on east and west walls is the St. Margaret's, or, as it is often called, Tradescant's Heart and Large Black Bigarreau. It is one of the finest Cherries grown, and the fruits when fully ripe are a blackish purple with a long stalk, and the flesh is dark purple. The fruits of this variety are not so sweet as some, but the slight acid flavour is not objectionable; indeed, when the fruits are quite ripe it is scarcely noticed. The tree with us is not quite so free as those named above, but it is a reliable cropper, and having a firm flesh it keeps well. Guigne de Winkler is our next latest dessert

Cherry, and it hangs well into October on a north wall. As regards quality, it does not compare with the earlier varieties, though the fruits are large and sweet and the flesh is red. It is well worth room for its keeping qualities: this belongs to the Duke section, and is best when the growths are not crowded in any way. The Black Tartarian, an earlier fruit than the last-named, and also known as the Black Circassian, is a splendid July sort, but grown on a cooler aspect may be had later. This is a delicious Cherry, a free grower and bearer, and one of the best. It does well in our light soil, and belongs to the Bigarreau section; but it did not do so well in the north in a heavy soil. Recently Messrs. Rivers staged a very fine late sort called Black Bohemian, and the new Noble is a very late fruit. These may become valuable, and with the list given above a long succession may be maintained.

Syon.

G. WYTHES.

THE CAUSE OF GRAPES CRACKING.

It is a well-known fact that only certain varieties of Grapes are subject to this evil, the worst, perhaps, being Madresfield Court, and many cultivators have felt compelled to abandon growing this fine Muscat Grape owing to this particular fault. The Frontignans, too, often crack badly, and Duke of Buccleuch is a kind requiring great care to prevent many of the finest berries becoming spoilt in this manner. Muscat of Alexandria sometimes shows a tendency to crack at a certain period of its growth. This variety usually cracks close round the stalk of the berry, which is more annoying than splitting at the apex, as the mischief is not so easily detected before decay sets in and spreads to the neighbouring berries. Several methods of prevention are resorted to by gardeners, such as cutting a notch in the wood just below the bunch, or boring a hole through the shoot, the object being to check the flow of the sap, a superabundance of which causes the berries to extend suddenly beyond the power of the skin to resist, thereby causing them to burst. Others allow a free lateral growth, with the object of carrying off any over-abundant supplies of food.

I do not dispute that these means are not sometimes effective, and have no doubt often served the purpose to which they were intended, but I think such methods must be considered unsatisfactory because they do not strike at the root of the evil. The two former modes savour somewhat of fifty years ago, or further back still. A free extension of lateral growth at a time when cracking is likely to take place is no doubt beneficial, but if too much is permitted to grow there is a danger of aggravating the evil instead of averting it by preventing a free circulation of air amongst the Vines. Moreover, if the shoots have been properly trained and not stopped back too hard from the commencement, there ought not to be any great necessity for leaf growth.

The cause of cracking, I am of opinion, frequently dates back to an earlier stage in the growth of the berries than the ripening period, at which time it always occurs, and is produced by a check, either from an insufficient supply of water, or too low a temperature and cold draughts. These conditions all contribute to hinder the free and uninterrupted growth of the berries, at the same time reducing the elasticity of the skin, which when the critical time arrives cannot expand sufficiently; consequently it bursts. I am convinced that cracking is more often caused through fear of giving water, with the idea of averting the malady, than by keeping the roots constantly moist. If ventilation is performed in a right manner there is no period at which Vines cannot be well watered; in fact, their roots should never approach dryness. I never hesitate to water our Vine borders, most of which are inside, at whatever stage the Grapes may be in, feeling confident that by ventilation I can prevent any ill effects, and I seldom have cracked berries, Madresfield Court and Duke of Buccleuch being treated in every respect like the other kinds. I should, however, be afraid to supply a soaking of

water when the Grapes were approaching ripening if they had not been previously well attended to in this respect; also I should fear the consequences of allowing a heavy fall of rain upon an outside border which had not been watered during a dry time. Roots in a thirsty state will pump up more food than the Vines can utilise, and this is one potent cause of cracking.

Although it is often produced by a check in the growth of the berries, it is more often caused by a too humid state of the atmosphere of the house and insufficient ventilation. Vineries containing varieties which are known to have a disposition to crack should on no account be forced after the berries have commenced colouring. The texture of both foliage and fruit at this stage will admit of a free circulation of air at all times, and the ventilators should be left open a little at night, according to the state of the weather, increasing the supply considerably during the day, but if the weather is cold and damp fire-heat cannot be dispensed with, a gentle heat being required during the absence of bright weather. Damping the borders must be sparingly indulged in during a dull and sunless time. Some assistants will go the daily round of damping and syringing let the state of the weather be what it may, and injury is often done in this way before it is noticed. Damping and syringing are operations requiring observation and thought, so as to adapt the inside to the outside conditions to a certain extent. A glass roof will not shut out the external air, and although we can by artificial means counteract the extremes which unfortunately fall to our lot in this country, it is well not to follow a too hard and fast line in the daily routine of firing, airing, and watering, but if the external conditions are against us, exercise a little patience and make the most of better weather when it comes. A.

APPLE JAMES GRIEVE.

THE raiser of James Grieve has certainly reason to be proud of his good work, for in the worst seasons we have had it has never failed. Though the crop was light it was good, whereas many sorts did not bear at all. It is a good amateur's Apple, as it is reliable. I would class James Grieve as a good companion to Lane's Prince Albert, the one very early, the other late, but both excellent. The variety Prince Albert has been described on so many occasions in these pages that I do not intend to dwell upon its merits, but I would point out the value of the variety James Grieve. It is a Scotch fruit, but it is certainly at home in the southern portion of the kingdom, and it will succeed in soils where Cox's Orange Pippin fails. It is by no means an old introduction, and is well worth a trial, not for its crop only, but for its good quality. It is a dessert fruit above medium size, and in season in September and October. This season, in spite of its heavy crop, the fruits are of good size, and they will at the early season named be a welcome addition to the dessert. It is not a long keeper, and our trees are grown as bushes. G. W. S.

THE INDOOR GARDEN.

IXORAS.

MY early acquaintance with *Ixoras* was with large specimen plants which used at that time to figure in all the horticultural exhibitions of any pretensions whatever; but all is now changed. The decline in popularity of specimen plants need not, however, entail their banishment from so many gardens, for effective little bushes may be grown in pots 6 inches, or in the case of some only 5 inches in diameter, and when in good condition they form a bright feature in the stove during the latter part of the summer and even early autumn. *Ixoras* have the reputation of being difficult to keep clean, but with care they give little trouble. Cuttings root easily if they are formed of the half-ripened shoots, selecting for choice those of

medium vigour rather than the very strong or very weak ones. A mixture of equal parts of silver sand and peat is very suitable for the cuttings, which should be inserted firmly into well-drained pots, putting three or four cuttings around the edge of a pot 4 inches in diameter. A close propagating case in the stove where there is a gentle bottom-heat is the best place for the cuttings, which under such conditions soon root. For established plants good yellow loam one part to two parts of peat and one of silver sand will meet their requirements. Insect pests may give trouble, as if the atmosphere of the structure is too dry thrips soon make headway, while aphides sometimes attack the young shoots. Vaporising will, however, destroy both of these, while if the syringe is freely used thrips are not likely to give any trouble. Scale sometimes makes its appearance, and mealy bug must be at once got rid of. When there is any danger of mealy bug lurking about a sharp look out must of course be kept, and if a bottle of methylated spirit with a small brush is close at hand a drop of the spirit will destroy not only the bug, but the woolly substance, which is so obnoxious, and that, too, without injuring the foliage in any way. To my mind the value of methylated spirit as an insecticide is not half enough recognised. Apart from the true species of *Ixora*, there is also a long list of garden varieties, so that a selection is by no means an easy matter, but the following are all good and distinct:—

Ixora coccinea.—A true species, native of the East Indies, from whence it was introduced many years ago. Botanically, numerous garden forms are but varieties of this, though distinctive names have been conferred upon them. A comparatively new form, *I. coccinea lutea*, has soft yellow flowers, quite distinct from the typical orange-red of the type.

I. Colei.—A garden variety with very deep green leaves and white flowers, which, though less showy than some of the others, attracts by reason of its (in the case of *Ixoras*) uncommon hue.

I. Prince of Orange.—Bright orange.

I. sanguinea.—Bright crimson, shaded with violet, particularly effective.

I. Westi.—A more robust grower than the others, with pretty pink blossoms.

I. Williamsi.—Varieties with reddish salmon-coloured blossoms are very numerous, but this is one of the best of that hue.

I. macrothyrsa or *Duffii*.—No selection of *Ixoras* would be complete without this species, but it is so different in every way from the others that it well merits a special paragraph. It is of strong growth, and forms an upright sparsely branched specimen clothed with long deep green leaves. The flowers, which are of a rich reddish crimson colour, are in terminal heads, which are in good examples considerably over 1 foot in diameter. Any attempt to form this species into a bushy plant will end in failure, as the massive flower clusters are its most imposing feature, and they are only borne on strong, well-developed shoots. This species is probably seen to the best advantage when consisting of three shoots, each about 4 feet high, and terminated by a huge head of flowers. H. P.

CRASSULA FALCATA.

THIS South African succulent, which, by the way, is more generally known in gardens as *Rochea falcata*, gives a bright bit of colouring to the greenhouse at this season. It forms a stout erect stem furnished with very succulent leaves, and flowers well when a foot or a little more in height. The individual blossoms, which are of a brilliant red colour, are small, but arranged in a large, closely-packed flattened head, which, when dotted over with the bright yellow anthers, is extremely telling. Its cultural requirements are simple, for it thrives in a mixture of loam, brick rubble, and sand, and can be readily propagated by taking off the single leaves and inserting them as cuttings. The principal thing in its culture is to give it plenty of light and full exposure to sunshine, for upon this depends the show of flowers. It is a

native of South Africa, from whence it was introduced in 1793, so that the (to many) charm of novelty cannot be claimed for it. It is a first-rate subject for a sunny window, and so situated I have noted many thriving examples of late. During the winter it will, from its succulent nature, need scarcely any water. This plant and its allies have had a great deal of shifting about within the last few years, for formerly a *Rochea* it is now a *Crassula*, whereas the old *Crassula coccinea* became classed under the head of *Kalosanthes*, and is now a *Rochea*. H. P.

A GENERAL CALENDAR.

ARRAERS OF WORK.

THE long spell of hot, dry weather through which we have just passed has had a tendency to throw much of the work in the garden behindhand. Watering and shading had to be attended to, and in gardens where labour is not too plentiful things are apt to get neglected.

Rose cuttings.—Where *Roses* are largely grown for beds these are best on their own roots, more especially if the soil is light, but on heavy and cold soils it is preferable to plant those budded on the Briar stock. The Hybrid China, the Hybrid Perpetual, and the Hybrid Bourbon *Roses* all lend themselves well to outdoor propagation. From the middle of September to the middle of October is the best time to propagate *Roses* in this way.

The best cuttings.—In taking the cuttings those that have well matured their growth and are strong and straight should be selected, and in detaching these from the parent plant take with them a small portion of the previous year's growth. In doing this do not remove many cuttings from one plant, or the parent will be much mutilated; on the other hand, a judicious thinning out is beneficial. In

Making the cuttings cut their base straight through just where the season's growth has started from, taking rather a thin slice of last year's wood to form a heel to the cutting. They should be shortened to about 10 inches or 12 inches in length, and in this condition they are ready for inserting in the soil.

Position for the cuttings.—A shady border with either a west or east aspect suits them well. I have also grown them successfully on a north border; in fact, anywhere where the soil is light and dry will answer well, and it is best to put them in precisely as is practised in almost every garden with Gooseberries and Currants, namely, digging the ground as you go on with the putting in of the cuttings. These should be in rows 12 inches apart, from 5 inches to 6 inches between each cutting, and so deep as only to have three to four eyes above ground, fixing each row well in the ground. All the protection that is necessary in winter—should the frost be very severe—is to sprinkle a little dry litter over them, removing it immediately when severe frost is over. These make well-rooted plants by midsummer without any further care than being kept clean and the surface of the soil stirred occasionally.

Sweet Peas.—Most of those that were sown early are now ripening their seeds quickly. This should now be gathered without a moment's delay. For seed gathering, especially of Sweet Peas, choose a fine day. Let the pods be perfectly dry. Select all the finest and best filled ones, and, where it is desirable to keep the colours separate, great care must be taken in gathering the seeds. All should be carefully labelled before putting them away.

The Belladonna Lily (*Amaryllis Belladonna*).—This beautiful Lily is very fine this season, the dry, hot weather just suited its requirements. They are now throwing up fine, long spikes of their handsome flowers; these should be seen to without delay. They have no foliage to protect them from wind and rain. Timely staking will, therefore, be beneficial, and a little shelter afforded when they are very much exposed.

Fruit gathering.—The protection of ripening fruit, and the gathering of it when it is fit, will now require the most urgent attention. Early Apples and Pears, if gathered a few days too soon,

will be insipid in flavour if kept in the fruit room. If on the other hand they are allowed to remain a few days longer on the trees than they ought to do, they become mealy; their precise period of maturity must therefore be watched. Careful handling at all times is most necessary, and they are best gathered during the hottest period of the day.

Mushrooms.—Where it is necessary to have a good supply of these from November till spring, this is the best time for making up the beds. In September the spawn naturally vegetates more freely than in any other month. It may be introduced when the heat of the bed is 70°, but when it declines, some time after spawning, cover the beds with a layer of straw. Care must be taken that this does not cause the soil to become too hot. If this is likely the covering must be made lighter. Between 55° and 60° is a good temperature for beds in bearing. T. B. FIELD.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THE meeting in the New Hall on Tuesday last was comparatively small, and there was a poor attendance. The Orchid committee gave an award of merit to a new Cattleya; the floral committee gave a similar award to four Dahlias, a hybrid Campanula, a Pink, and a bedding Begonia. A new Raspberry obtained recognition from the fruit committee. There were several interesting collections of Gourds among the exhibits in the hall, and in the afternoon Mr. Odell gave a lecture, illustrated by limelight, about them, and urged their extended culture for decorative effect in the garden.

ORCHID COMMITTEE.

Present: Mr. Harry J. Veitch (chairman), Baron Sir Henry Schroder, Bart., Messrs. James O'Brien, de B. Crawshaw, H. Ballantine, J. Wilson Potter, W. Boxall, W. H. Young, J. W. Odell, H. A. Tracy, T. W. Bond, G. F. Moore, James Douglas, H. Little, and W. A. Bilney.

Messrs. Sander and Sons, St. Albans, exhibited a group of Orchids, in which *Laelio-Cattleya* Henry Greenwood and *L.-C. bleichelyensis* were conspicuously bright. *Phaius asworthianus*, with yellow sepals and petals and red-brown lip; *Brassia veirucosa*, with quaint green black-spotted flowers; *Phalaenopsis esmeralda*, several *Cypripediums*, *Chondrorhyncha* Chestertonii, *Zygo-Colax Veitchii*, and *Miltonia Regnellii* concolor were other notable plants. Silver Flora medal.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, made a pretty display with Orchids in variety. *Cattleya gaskelliana* alba, *C. dowiana*, *C. granulosa*, *C. speciosissima*, *C. Grossi*, and *Laelio-Cattleya Ingramii* were well represented, and others good were *Odontoglossum crispum*, a beautiful pale variety of *Dendrobium Phalaenopsis*, *Vanda tricolor*, *Brassia lawrenceana longissima*, *Phalaenopsis denticulata*, *P. violacea*, and *Aerides Lobbi*, with rather large rich rose flowers in a drooping raceme. Silver Banksian medal.

Messrs. James Veitch and Sons, Limited, Chelsea, sent a collection of hybrid *Laelias* and *Laelio-Cattleyas* that made a very attractive display. Among them were *L. Pacuvia* (purpurata × *tenebrosa*), *L. splendens* (crispata × *purpurata*), *L.-C. bleichelyensis*, *L.-C. haroldiana* (tenebrosa × *hardyana*), *L.-C. Brvan*, *L.-C. callistoglossa*, *L.-C. digbyano-pigias*, and *Zygo-Colax Veitchii* (crispum × *jugosum*). Silver Flora medal.

The Hon. Walter Rothschild, Tring (gardener, Mr. A. Dye), sent a collection of Orchids, such as *Masdevallia*, *Nanodes*, *Restrepia*, *Coleogyne speciosum*, and *Eranthis zygopetaloides*. A botanical certificate was given to *Masdevallia burhidgiana*. Silver Banksian medal.

Several *Cypripedium* hybrids were shown by J. G. Fowler, Esq., Gledbelds, South Woodford; they were *callo-rothschildianum*, *Penelope* (Morganiae × *Veitchii*), and *l'Ansoni* (Morganiae × *rothschildianum*).

Captain G. L. H. Hird, C.I.E., Westnort, Tethbury, showed *Zygo-Colax wicanianus superbus* (*Z. intermedium* × *C. jugosum*), and also *C. Iris Westnortii* variety (*C. bicolor* × *C. aurea*) that obtained an award of merit.

Cattleya × *Marshall Oyama* (*C. granulosa* × *schofieldiana* × *anrea dowiana*) was shown by C. L. N. Ingram, Esq., Elstead, Godalming.

R. J. Measures, Esq., Cambridge Lodge, Camberwell, showed a *Zygotatium* hybrid (*maxillare* × *jorisanum*).

A very finely flowered pseudo-bulb of *Cattleya Harrisoniae*, bearing a raceme of ten flowers, while there were practically no roots at all, was shown by Gurney Wilson, Esq., Glenthorne, Haywards Heath. It is remarkable that a pseudo-bulb with hardly any roots at all should produce such an unusually fine raceme, while well-rooted plants rarely bear more than four flowers per bulb.

NEW ORCHID.

Cattleya Iris Westnortii variety.—The parents of this striking hybrid are *Cattleya bicolor* and *C. anrea*. The sepals and petals are green with a rosy tinge, with which the bright purple lip contrasts well. From Captain G. L. Hird, C.I.E., Westnort, Tethbury (Orchid grower, Mr. Alexander).

FRUIT COMMITTEE.

Mr. A. H. Pearson (chairman), Messrs. F. Q. Lane, J. Jacques, Owen Thomas, E. W. Gilbert, J. Lyne, H. J. Wright, George Kelf, John Basham, William Pope, Alex. Dean, S. Mortimer, T. W. Bates, J. McIndoe, and J. Cheal.

Messrs. William Paul and Son, Waltham Cross, exhibited a group of fruit trees in pots, including Apples, Pears,

Plums, and Peaches. They were well fruited, the Apples and Pears particularly bearing heavy crops. Very good single dishes of Allington Pippin, Banmann's Reinette, Duchess of Oldenburg, Fearn's Pippin, King of the Pippins, Peasgood's Nonsuch, The Queen, and others were exhibited. Silver-gilt Knightian medal.

Mrs. Brightwen, The Grove, Stanmore (gardener, Mr. J. Odell), exhibited a most interesting collection of ornamental Gourds, in many quaint and curious forms. We noticed White Egg, Large Bell, rotunda alba, Gooseberry Gourd, White Pear, White Turk's Cap, Ostrich Egg, Striped Bell, Yellow Custard, Yellow Spoon, Red Turk's Cap, and Large Green Apple, all more or less resembling the objects after which they are named. Silver Knightian medal.

Captain A. E. Speer, Sandown Lodge, Esher (gardener, Mr. R. Perry), exhibited a collection of ornamental Gourds, among them being Green Turk's Cap, oak-coloured Wart Gourd, White Club Gourd, Small Green Striped Pear Gourd, Orange Gourd, Small Three Coloured Gourd, Red Turk's Cap Gourd, White Onion Gourd, and others, making a very interesting display. Bronze Knightian medal.

Harry J. Veitch, Esq., East Burnham Park, Slough, exhibited a collection of ornamental Gourds in great variety of size, shape, and markings.

An extensive collection of Gourds was shown by G. Ferguson, Esq., The Hollies, Weybridge (gardener, Mr. F. W. Smith). They were represented in great variety, in many quaint and curious forms and rich and sombre colouring. The Orange Gourd was, perhaps, the richest in colour. The Japanese Climbing Cucumber, Luffa Gourd (Vegetable Sponge), the Musk Melon, and others were among those shown. Silver Banksian medal.

Raspberry Penwill's Champion was shown by Mr. G. Penwill, Totnes.

Grape Drachenberger Seedling, a good deal resembling Foster's Seedling, was shown by Mr. E. W. Gilbert, Drachenberger, Potsdam, Berlin.

Melon Norbury Hero, a scarlet flesh variety, was sent by Mr. G. Kent, Norbury Park, Dorking.

Grape Edith, a Sweetwater variety, was shown by Mr. W. Aldridge, Clarence Road, Teddington.

Mr. W. Seward, Hanwell, sent Tomato Hanwell Victory.

A cultural commendation was given to Mr. W. Ruppell, Ruppell Park, S.W., for some fine fruits of Apple Bietigheimer.

Messrs. James Veitch and Sons, Limited, Chelsea, showed Tomato Gilbert's Seedling, a fairly large round fruit of rose-red colour.

Mr. Charles Ross, Welford Park, Newbury, showed Apple Ruddy (of deep red colour), Apple Echo, and Pinn Trump.

A cultural commendation was given to Mr. R. Lye, The Gardens, Sydmonton Court, Newbury, for Runner Bean Sydmonton Exhibition.

Mr. Arthur Otteaway, Swanley, Kent, showed Apple Otteaway's Pippin, a pale yellow fruit.

Mr. Richard Anker, Napier Road, South Kensington, exhibited a new fruit gatherer that has many advantages. At the end of a rod, some 8 feet or more long, is a cup-shaped receptacle made of tin and lined with felt. One-half of this receptacle is made to open by means of a lever at the base of the rod. When the fruit is inside the cup a trigger is pressed that causes the cup to close round the fruit, which may then be gathered.

Mr. G. Pope, Castle Gardens, Highclere, Newbury, exhibited a collection of Apples, many of the varieties being finely coloured. Peasgood's Nonsuch was an excellent dish, and so were Lady Sudeley and Duchess of Oldenburg.

Ornamental Gourds in variety were shown by the Horticultural College, Swanley.

Lubrose, an imperishable paint for greenhouses, &c., was shown by Mr. Drury, manager of the Lubrose Paint Company, Moorgate Station Chambers.

NEW FRUIT.

Raspberry Colwell's Red Diamond.—This appears to be a valuable late Raspberry. The fruits are above medium size, dark red in colour, of sweet and pleasant flavour, and from the fruiting branches exhibited this variety evidently crops well. From Mr. J. B. Colwell, Sidmouth. Award of merit.

FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), Messrs. C. T. Drury, H. B. May, R. Dean, J. F. McLeod, R. Hooper Pearson, J. Jennings, James Hindson, C. R. Fielder, C. Dixon, W. Bain, Charles E. Shea, Amos Perry, William Canthbertson, George Nicholson, Charles E. Pearson, J. W. Barr, R. C. Notcutt, H. J. Jones, W. P. Thomson, E. H. Jenkins, William J. James, Edward Mawley, George Paul, and Charles Ellick.

Messrs. J. Hill and Sons, Lower Edmonton, set up a large table of Ferns in variety. There were *Adiantums* and *Davallias*, *Acrostichum* and *Nephrolepis*, *Branea* and *Polypodium*, with *Gymnogramma*, &c., all representative of their kind. Some distinctive things were *Davallia assanica*, with hoary rhizomes and dark acuminate fronds; *Platycerium Hillii*; *Acrostichum quercifolium*, with fertile and barren fronds; *Lomaria L'Herminieri*, with tree-like aspect and red fronds. Probably *Asplenium marginatum* was the most distinct in the group. The pale green fronds and oppositely placed pinnae are marked features of the plant. Silver Banksian medal.

A magnificent specimen some 8 feet in diameter of *Davallia filifolia elegans* came from H. Baxter, Esq., Hutton Park, Brentwood (gardener, Mr. Holloway). A cultural commendation was given and obviously merited.

The Cannas from Messrs. Cannell and Sons, Swanley, were exceptionally good, well grown, and well flowered. Among the many excellent varieties shown Miss B. Brunner, yellow, spotted red; Niagara, scarlet and gold; Duke Ernest, orange-scarlet; C. Molin, salmon-orange; Black Prince, dark crimson; and Riese Von Stuttgart, orange-scarlet, were among the finest. *Lilium speciosum* and Maidenhair Ferns made the margin, with large Palms in the background. Silver-gilt Flora medal.

Mr. Amos Perry, Winchmore Hill, again showed a large table of cut hardy flowers. Japanese Anemones, Phloxes,

Tiger Lilies, Montbretias, *Liatris pycnostachya* (very fine), *Cimicifuga cordifolia*, the double *Gypsophila*, *Eudelia variabilis*, *Lilium speciosum* Kretzeri, *Lobelia* Queen Victoria, *Echinacea angustifolia* (very fine), *Campanula azurea*, with many *Scandovras*, the bold *Kniphofias*, *Helenium cupreum* (very good in colour), *Aster Elsie Perry* (a nice tone of pink), and *Senecio pulcher* were among the best. Water Lilies were also well shown, with *Aponogeton distachyon*, &c. Silver Banksian medal.

The collection of hardy Heaths and allied plants from Mr. David Russell, Brentwood, was an interesting lot. Large groups of *Erica vulgaris* Allportii and *E. v. alba stricta* were represented by 3 feet patches. *E. v. Hammondii* (white), *E. v. plena*, *E. v. carnea grandiflora*, *E. v. rigidus*, and *E. vagans alba minor* were among the more distinct.

Gaillardias, Lobelias, and Pinks were all grandly shown by Mr. B. Ladams, Shirley, Southampton. The Gaillardias were extremely fine and gay. Some very good dark forms were noticeable. The perpetual Pinks Marion and Florence were in good form, and the hybrid forms of *Lobelia siphilitica* in much variety. These latter, if not indefinitely increased, will be welcome in the garden by reason of their distinctive shades.

Single Petunias from Messrs. James Carter and Co., High Holborn, indicate a strain of the highest excellence, from self and yellow-eyed forms to beautifully veined flowers that defy description. The strain is known as Empress, and in the large size of the blossoms and the infinite variety is of much value.

Herbaceous Phloxes from Messrs. Gunn and Sons, Olton, Birmingham, were fine and very well shown, though too densely arranged. Among the more distinct we take *Sylphide* (white), *Coquelicot*, *Mme. Mera* (blue and white), *Tour Eiffel* (salmon), *Etna* (scarlet), *Eden* (white), *Molière* (rose), *Iris* (violet-purple), *Tapis Blanc* (large white), and *Esperance* (blue, white eye). *Aurora Borealis*, crimson-scarlet, was also good. Silver Flora medal.

Single Cactus and Pompon Dahlias were contributed by Messrs. Cheal and Sons, Crawley, making a pretty display. In the latter *Neissa*, Queen of Whites, and Ernest Harper were very distinct, the latter bright scarlet, the first a rosy shade and very charming. Darkness and The Bide are two fine singles, with Princess of Wales, rosy lilac, very good.

A small batch of Cactus Dahlias came from Messrs. J. Stredwick and Son, St. Leonards-on-Sea. Two of these will be found under awards, and of the rest *Thos. Parkin*, orange, and *Edith Box*, white, are the best. Bronze Flora medal.

New Pompon Dahlias were also sent by Mr. Charles Turner, Slough. *Mignon*, maroon; *Sylvia*, rose-lilac; and *Queen of Whites* being noteworthy.

Mr. Mortimer, Farnham, in a small set of Cactus Dahlias had *Starlight*, rose and white; *Innocence*, creamy white and yellow centre, a large flower; *Alexandra*, maroon-crimson, very fine, with *Vivid*, a very striking scarlet.

Mr. H. Shoemith, Woking, also had Cactus Dahlias in variety, an award being given to one named W. Hopkins. *Jeanette*, yellow; *T. Stevenson*, maroon; and *Mrs. F. Wellesley*, white, were also from the same exhibitor.

Early Chrysanthemums were shown by Messrs. W. Wells and Co., Limited, Redhill, in great variety. Such yellows as *Champion*, *Carrie*, *Magpie*, and *September Gold* being good. It is obvious, however, that the heat has been too much for these flowers, and in all probability the later buds will be more satisfactory.

A very attractive group of *Daedalanthus parvus* was shown by Messrs. Veitch and Sons, Chelsea.

Ferns and *Bouvardias* in distinctive kinds were a very pleasing feature from Mr. H. B. May, Edmonton. Of *Bouvardias*, *Priory Beauty*, *Jasminoides*, *King of Scarlets*, *Mrs. R. Green*, *Dazzler*, and *Princess of Wales* were good. Some shrubby *Veronicas* were also staged.

The *Begonias* from Messrs. Blackmore and Langdon, Bath, were representative of a very fine strain, large flowers, good and decided colours, with many shades in all the kinds, single and double. Indeed, it is scarcely possible to see where further improvement can come in, so good generally is the strain. Baskets of double bedding sorts were also set up, and of these we note *Marquis* of Stafford, crimson; *Hollyhock*, pink; *Argus*, scarlet; and *Calliope*, soft pink. All were good and very dwarf in habit. Silver Flora medal.

Messrs. R. and G. Canthbert, Southgate, staged an excellent group of *Lilium longiflorum*, the plants, though in quite small pots, carrying in some instances as many as nine flowers.

Hardy cut flowers from Messrs. Wallace and Co., Colchester, were in good variety, including such things as *Helianthus mollis*, many fine *Kniphofias*, *Hemerocallis aurantiaca major*, Lilies of the long-flowered, Tiger, and speciosum sections, with *L. auratum rubro-vittatum* and others. Many good *Gladioli* were also shown, with *Watsonia rosea*, *Colchicum Bornmuelleri*, *Polygonum amplexicaule*, *Amaryllis Belladonna*, *Sternbergia lutea major* (very showy, many bulbs showing three spikes), &c. Silver Banksian medal.

Messrs. Barr and Sons, Covent Garden, had a large exhibit composed chiefly of *Gladioli*, China Asters, *Snaydragons*, *Kniphofias*, *Phloxes*, and the like. The China Asters were of a representative character as showing the sections of the flower, and contained some very minute forms. *Vallota purpurea* was exceedingly good and brilliant, and of this a large mass was shown.

Messrs. Sander and Sons, St. Albans, had several of the decorative (Rex) *Begonias*, such as *His Majesty*, *Our Queen*, and *Mrs. H. G. Moon*. All were exceedingly attractive and very beautiful to look upon.

Messrs. J. Peed and Son, West Norwood, S.E., had a miscellaneous group, in which succulents, *Salvias*, alpinas in pots, hardy cut flowers, *Aster Anellus* vars., *A. acris*, *Campanula carpatica* in variety, *Sunflowers*, *Bamboos*, *Lilies*, *Statice*, and other such things played a prominent part.

Prince's Oxford Roses made one of the most enjoyable groups in the exhibition. It was indeed an array of beauty and variety that would be regarded with satisfaction at and season, and not less so at the present time. Some exceptional

things were Frau Karl Druschki, of almost wax texture; Maman Cochet and its white form; Billard et Barré, rich yellow; Reve d'Or, Souv. de William Robinson, Mildred Grant, Marie van Houtte, W. A. Richardson, Souv. de C. Guillot, &c., really choice and beautiful kinds; Rosa pomifera was shown in fruit, many fruiting branches of Rosa rugosa were used as a margin. Silver-gilt Banksian medal. A very fine Nymphaea was N. Marana of rose-carmine shade. Shown by the Hon. Walter Rothschild, M.P., Tring Park, Tring.

Nertera depressa and Funkia grandiflora were from Mr. W. Roupeil.

Cut branches of Cassia marylandica were shown by Messrs. Veitch and Son, Exeter.

Chironia ixifera, with an endless profusion of pink blossoms and buds, came from the gardens of Sir Trevor Lawrence, Bart., Dorking. It is a charming plant suited for a quite cool house.

Sir Trevor Lawrence, Bart., also showed some enormous heads of blossoms of *Ixora Duffi* (syn. *I. macrothyrsa*). They had a diameter at least of 12 inches, the brilliant orange-red flowers making a fine display. The plant is almost as remarkable for its great leaf growth as for its heads of blossoms, the first of these often being 10 inches or 12 inches long. A cultural commendation was awarded.

NEW PLANTS.

Dahlia Edina (Pompon).—A yellow-flowered self-coloured variety, very neat and compact, and of moderate size. From Mr. Charles Turner, Slough. Award of merit.

Dahlia Fairy (Cactus).—A flower of medium size and elegant recurring florets, having a more pointed tendency than usual. It is white, though not absolutely pure. Award of merit.

Dahlia J. B. Riding (Cactus).—A pleasing tone of pale orange with a tinge of salmon. It is a flower of considerable merit. These two were from Messrs. J. Stredwick and Sons, St. Leonards-on-Sea, each receiving an award of merit.

Dahlia W. Hopkins (Cactus).—A handsome variety of a maroon shade, the central florets tinted with violet-purple. The flower is of a good type and well formed. From Mr. H. Shoesmith, Woking. Award of merit.

Campanula hybrida Fergusoni.—This is virtually a dwarf and frail growing *C. pyramidalis* in general appearance, yet without the close dense setting of the flowers on the spike as seen in *C. pyramidalis* and *C. carpatia*, with a strong leaning to the former in the leaf growth and rootstock. The pale blue flowers are large and cup-shaped and are freely produced on pedicels 3 inches or more long. The plants shown were about 2 feet high, but they were probably the result of cultivation under glass. From G. Ferguson, Esq., The Hollies, Weybridge (gardener, Mr. F. W. Smith). Award of merit.

Pink Florence was shown by Mr. B. Ladham, Southampton, and received the award of merit.

Begonia Argus.—A new type of double-bedding Begonia, having the flowers on short, erect sturdy stems, just clear of the foliage, the blossoms are situated at the top of the stalk, are flatly exposed, and show well. The plant is very dwarf, not more than 6 inches or so to the top of the expanded flower, which is crimson-scarlet. From Messrs. Blackmore and Langdon, Bath. Award of merit.

THE NATIONAL DAHLIA SOCIETY'S SHOW.

AFTER holding one annual exhibition in the Royal Horticultural Society's Drill Hall, Westminster, the committee, being unable to come to terms with the society with respect to holding the show in the new hall, returned to the Crystal Palace, where the exhibition was held on the 2nd and 3rd inst. That Dahlias suffer as exhibition flowers when staged in the Palace there can be no doubt, and a good deal of tabling was not filled. The attendance of the public was poor. We do hope that an effort will be made to hold the show next year in the Royal Horticultural Society's new hall.

SHOW AND FANCY BLOOMS.

It was very evident that taste for these big rounded flowers is giving place to that for the beautiful Cactus forms, as classes for them have been materially reduced. In the class for forty-eight show flowers only three lots competed, Mr. S. Mortimer, Farnham, Mr. J. Walker, Thame, and Messrs. Keynes, Williams and Co., Salisbury, taking the prizes in this order. A few really good blooms of their kind were Dr. Keynes, Lord Salisbury, Arthur Rawlings, Mrs. G. Noyes, John Hickling, and John Standish. In the class for twenty-four blooms Mr. W. Treseder, Cardiff, was first. Fancies had classes for twenty-four and twelve blooms respectively. These all have distinctive striped, speckled, or tipped markings. Mr. S. Mortimer had the best twenty-four, Mr. Walker coming second. Good blooms in these stands were Peacock, Mrs. Saunders, Watchman, Dandy, H. Clark, Comedian, Emin Pasha, and Lottie Eckford.

POMPONS.

These miniature shows and fancies were also less plentiful than at previous exhibitions. One feature in their favour is their wonderful floriferousness and small blooms. Mr. Turner of Slough was first in the class for twenty-four bunches, Messrs. Cheal and Sons, Crawley, second, and Mr. Seale of Sevenoaks third. A fine selection from these are Elsa, Gaunymede, Thalia, Nerissa, Adelaide, Edina, Bacchus, Silver, Darkes, of All, Buttercup, and Queen of Whites. In the smaller class these varieties were practically repeated.

CACTUS VARIETIES.

These wonderfully pretty flowers were in dominating force, and constituted the chief attraction. Interest centred in the principal trade classes, as it is in these new varieties are mostly found. In the vase classes flowers presented a remarkably beautiful appearance, and were most artistically arranged. In the class for eighteen bunches of Cactus varieties Mr. Stredwick, St. Leonards, Messrs. J. Cheal and Sons, and Messrs. Keynes, Williams, and Co. took prizes in that order. Very beautiful in Mr. Stredwick's collection

were J. B. Riding, yellow centre, orange-red petals (the silver medal Cactus bloom of the show); Columbine, Ella Kremer, Pearl, England's Queen, and Antelope. Mr. H. Shoesmith, Woking, had the best twelve bunches, his varieties including Phyllis, H. W. Silem, W. E. Dickson, and Mrs. Francis Wellesley. There were two classes for Cactus flowers shown on flat boxes, but the effect was very poor. When forty-eight bunches constitute a class the labour of judging comparatively even flowers is great. Messrs. Stredwick and Keynes, Williams and Co. took the prizes in the large class, and amongst flowers in commerce, such as can be purchased cheaply, were Mr. Tulloch, J. W. Wilkinson, Peach Blossom, Mrs. E. Mawley, F. M. Stredwick, and Raymond Parks.

VASE CLASSES.

In these Cactus flowers were seen to great advantage. Mr. Seale came first out of five competitors, who staged in all sixty vases. His collection of twelve were effectively dressed with foliage and sprigs of berried shrubs. The varieties included Florence Stredwick, Mrs. E. Mawley, Mrs. H. Jones, Mrs. Brousson, and others; Messrs. Cheal and Walker were second and third. With six vases Mr. H. A. Needs of Woking was first. With three vases Mr. P. W. Tulloch (the secretary) was a good first; he was also first for a vase of singles. Mr. W. Treseder had the prettiest bouquet. We should like to see drapery addition to these exhibits prohibited.

SINGLE DAHLIAS.

Only two trade classes are reserved for these very beautiful, if somewhat fleeting, flowers. Messrs. J. Cheal and Sons had the best twenty-four bunches, too stiffly arranged, but the flowers most beautiful. Striking amongst these were Snowdrop, Princess of Wales, Miss Roberts, Naomi Tighe, William Parrott, and Robin Adair. In other classes in the show these varieties were largely repeated. Competition in the amateurs' classes was fairly good. The silver medal awarded to the best Cactus in these classes went to Mr. McGrath, Huddersfield, for Rainbow, a beautiful pink variety.

Trade groups were largely shown. Messrs. Cannell and Sons, Swanley, had nearly 200 bunches of Cactus, decorative, and collarette varieties, set up with Palms, Eulalias, Kochias, and Gypsophila, a very beautiful exhibit. Hobbes and Co., East Dereham, had 100 feet run of tabling filled with bunches of Cactus and Pompon varieties, charmingly arranged. Messrs. T. S. Ware and Co., Feltham, and Messrs. William Cutbush and Sons, Highgate, both staged very large and most elegantly grouped collections, very artistically displayed. Mr. J. T. West, Brentwood, had Dahlias in considerable variety, inclusive of several of his own raising. Messrs. J. Peed and Sons, Lower Norwood, showed a large group of Caladiums and one of Gloxinias; and Mr. J. Gwilliam, New Eltham, had several hundreds of double and single Begonia flowers, flatly arranged in groups of colours. Honorary awards were made to all these exhibits.

CERTIFICATED SEEDLINGS.

It was worthy of note that out of nearly sixty seedling Cactus varieties staged for certificate only nine obtained them. A much higher standard is now required than was formerly the case. The following obtained awards:

Miss Dorothy Oliver.—Lemon centre, white petals.
Janette.—Yellow. Both from Mr. H. Shoesmith.
J. B. Riding.—Yellow centre, orange-red petals.
Fairy.—Pure white.
Ella Kremer.—Rich peach self.
Tricolor.—White, shaded yellow, striped red. These four were from Messrs. J. Stredwick and Son.
Rosy Morn.—White centre, rich pink petals.
Cockatoo.—Yellow centre, white petals. These two were from Messrs. Keynes, Williams, and Co.
Thomas Parkin.—Bright red salmon self. From Mr. J. T. West.
Mrs. Hobbs (Show).—Pure white. From Mr. T. Hobbs, Bristol.
Mr. Needs (Single).—Deep red centre, pale yellow petals. From Mr. F. W. Seale, Sevenoaks.

ELVTH SHOW.

THE eighteenth annual show of Elvth Floral and Horticultural Society was held in Bath Terrace Grounds on the 27th ult. The entries were as numerous as in previous years, and the uniform quality of many of the exhibits gave the judges a deal of trouble. That the show fully maintained the position as being one of the principal fixtures in the North was to be seen in many ways, especially by the attendance of some of our acknowledged floral and vegetable experts. Plants were magnificent in bloom, table decorations made an extensive display, and Roses and Dahlias formed features of the show. The principal prize takers were as follows: Messrs. Harkness, Thomas Battensby, J. Cawthorne, M. Allison, G. Gardener, J. Robson, S. Bewick, T. Coxon, W. Taylor, M. Young, J. Marshall, E. Nicholson, W. Forster, J. Swann, A. Allen, W. Brown, and R. Nelson.

RYE DISTRICT FLOWER SHOW.

THE ancient Cinque Ports town of Rye has a long and honourable reputation for successful gardening, and the history of its flower shows goes back a very long way, the most notable chapter, perhaps, being contributed by Charles Dickens, who, in his journalistic days, came from town to describe, in his inimitable way, "Our Flower Show." Of late years the "annual" had fallen into abeyance, the monthly shows of two thriving societies being considered sufficient. Last year, however, a determined effort resulted in the resuscitation of the Rye District Show. An excellent show was completely spoiled, financially, by a deplorably wet day.

Nothing daunted, however, the hon. secretaries, Conncillor F. Herbert Chapman and Mr. J. L. Deacon, backed by energetic and enthusiastic committeemen and guarantors, zealously renewed their exertions, and arranged the second show of the new series for the 30th ult., when their efforts were rewarded with the most complete success, so far as the show itself was concerned, there being nearly 800 entries, double last year's number.

The splendid show made by the entries proper was enhanced and amplified by the grand display of non-competitive exhibits, in which Mr. Monnt. Canterbury, led the way with a magnificent lot of Roses.

Messrs. C. and A. Clarke, Dover, staged cut flowers; R. Wallace and Co., Colchester, made a grand show of Gladioli, Montbretias, Liliums, and other cut flowers; and Mr. E. Potten of Camden Nursery, Cranbrook, had some fine Antirrhinums. Mr. F. Thomas, Hastings, contributed charming decorations. Mr. W. N. Knight, Belle Vue Nursery, Rye, had a good display, effectively staged, of Dahlias. Mr. Secretary Chapman exhibited pot Lilies of the Valley.

In the open division Mr. Puxted, gardener to Sir George Warrender, Leasam, Rye, came first for a group of plants; Mr. J. Austen, gardener to Dr. Skinner, Rye, came second. Mr. Puxted proved himself the champion of the show in the matter of prizes. Mr. Secretary Chapman, a specialist in Sweet Peas, carried off the first in that class, with the aid of his gardener, Mr. Masters. Mr. Henry James, the novelist, through his gardener, Mr. G. Gammon, kept the first for Geraniums and Apricots to Rye. Mr. G. Bannister, gardener to Mr. H. C. Burra (president of the show) took the first for collection of vegetables; and the finest Figs came from Mr. C. Lyon Liddell, Peasmarsh. There were twenty-four dishes of Potatoes, almost equal in excellence, and very puzzling to the judges.

The fruit display was not very large, but included some good Grapes and splendid Apples, and the Roses, bonquets, and pot plants set off the other exhibits to advantage. The Fern competition was, perhaps, the weakest.

The subscribers' and amateurs' marquee contained some very good fruit and vegetables, but the cut flowers were not particularly numerous, nor was the competition very close. As a whole, however, the display was praiseworthy. In the cottagers' class, always a very strong feature at Rye, there was a very fine display, including the finest Runner Beans and Beet in the show, capital Marrows and ridge Cucumbers. The cut flowers, too, were very noticeable, and the judges and professional florists agreed that Mr. H. Tanton, a keen allotment gardener, had the finest Cactus Dahlias in the exhibition.

BATH FLORAL FETE.

ANY anticipation the promoters of this show—which was held on August 31 and September 1—may have had of making it this year a financial success met with a complete damper on the opening day. The rain, which commenced early in the morning, continued with increasing severity until nearly closing time. With regard to the exhibition it was undoubtedly a grand display throughout, and in most sections a very decided advance, both in quality and quantity, as compared with some previous years. If there was any falling off in the number of specimen plants, there certainly was not in the quality, for nothing could be finer than the exhibits of Messrs. James Cypher and Sons of Cheltenham, who secured all the premier prizes in this division, Messrs. J. B. Woods and Son and Mr. G. Tucker of Trowbridge winning second prizes. Fuchsias are remarkably well done at the Bath show; the nine splendid trees, 10 feet to 12 feet high, that secured the first prize for Mr. H. W. Tugwell of Crow Hall (gardener, Mr. W. Parrott) showed skilful culture.

Cut flowers, which were no doubt the feature of the show, were accommodated in a large tent. An item that lent effect and colour was the system of showing Cactus Dahlias on stands, a great improvement on the old flat boxes. Cut Begonias as well as the plants were very fine, the doubles shown by Mr. F. J. Farr (first) being especially so. The collections of Gladioli made a grand display, Mr. J. Mattock of Oxford, Mr. W. T. Mattock of Headington (first and second for thirty-six spikes), Messrs. A. A. Walters and Sons, and the Cedar Hardy Plant Nursery (first and second for twelve spikes) all showing perfect flowers. Asters and Dahlias occupied much space. The best twenty-four show and fancy Dahlias came from Messrs. J. Cray and Sons, Frome, and the best twelve from Mr. Gilbert Dersley. The Cactus varieties made a wonderful display, Mr. G. Humphries securing the honours for twelve bunches, and Messrs. Cray and Sons for twelve bunches of Pompons. Roses, although in considerable number, were overshadowed by their more gaudy neighbours. Teas, of course, predominated. For twenty-four blooms Messrs. Jefferies and Sons, Cirencester, were first, Messrs. Perkins and Son, Coventry, being second. For twelve blooms Mr. J. Crossing, Penarth Nurseries, N.W., was first with a fine stand. In Teas Messrs. J. Mattock and J. Jefferies and Sons took the leading positions, the vases of Teas shown by the latter being very pretty. The whole of the centre stage was taken up with collections of hardy flowers, both competitive and non-competitive. In the class confined to a space 12 feet by 3 feet Messrs. A. A. Walters were placed first, Mr. Fred Eams second, and Messrs. B. Ladham, Limited, Southampton, third, the latter sacrificing effect to number of varieties. Hardy annuals, Zinnias, Marigolds, and cut Gloxinias were all shown in large numbers and generally of fine quality.

The decorative classes were arranged in another tent, and very pretty it looked. Sixteen decorated dinner tables filled the centre of the tent. Mrs. T. H. Woodland was the first prize winner; second, Mrs. Colson Hale. We would strongly recommend the committee another year to follow the example of Shrewsbury and exclude Orchids from this class. Bonquets, although numerous, were generally poor. Bowls of flowers were very pretty. Perhaps the most interesting feature in this tent were the wild flowers.

FRUIT.

Bath shows have a reputation for good fruit, and that reputation was in no way diminished by this season's exhibition. Grapes made an imposing array the whole length of the tent. Apples, of which there were some 150 dishes, were grand, especially the dessert varieties, the colouring being remarkable, Beauty of Bath being most prominent, and amongst the kitchen varieties Peasgood Nonsuch was

in all cases very fine. Peats were numerous, but averaged small in size. Mr. J. W. Fleming, J.P., of Chilworth Manor, near Southampton (gardener, Mr. W. Mitchell), was first for eight dishes of fruit, the Right Hon. W. H. Long, M.P. (gardener, Mr. Strugnell) being second.

To the Grape classes Mr. Fleming was again successful, being first for the twelve bunches in four varieties, three bunches of Black Hamburg, and for two bunches any other variety. The Madresfield Court that won this last-named prize were undoubtedly the finest Grapes in the show. For white Grapes Mr. Fleming was second, Mr. W. Marsh of Bath being first with better-coloured Muscats.

Eighteen Melons were staged, the first for green flesh (The Islander) going to Mr. H. Chislett, Trowbridge, and the first for any other variety to Mr. G. P. Fuller (gardener, Mr. H. Cook), with a scarlet flesh not named. Peaches were not numerous, but all good, especially the first, from the Hackwood Nurseries, Frome.

For three dishes of Pears Mr. H. C. Holder, Bath, was first, and for three dishes of dessert Pears Mr. F. Wait, who also was placed first for three dishes dessert Apples, Mr. W. A. Hicks being an easy first in twelve of one variety with splendid samples of Beauty of Bath. The first prize for three dishes of culinary Apples was taken by Mr. C. C. Tinday (gardener, Mr. C. F. Fewell), Wells, with monster fruits.

Vegetables were staged in the open. In the twelve varieties, open, quantity seemed to rule rather than quality, Mr. H. E. Holder being first and Mr. E. Hall second. The cottagers' vegetables were very fine and well staged, and deserved a fuller notice than our space will permit. Special classes were offered by Messrs. Sutton and Sons, Reading, and Webb and Sons, Worsley.

Trade exhibits, which occupied a large space at this show, were exceptionally good. Messrs. B. Ladams, Limited, Southampton, had a fine stand of their specialities. Messrs. James Garaway and Co. of Bristol made an imposing array with herbaceous flowers. Messrs. G. Cooling and Sons of Bath showed fruit trees in pots, Apples and Pears, and some very fine zonal Pelargoniums. Messrs. Blackmore and Langdon, Twerton Nurseries, showed beautiful seedling Begonias. Mr. Maurice Prichard, Christchurch, Hants, Messrs. Jarmar and Co., Chard, and Messrs. Isaac House and Sons, Westbury-on-Trym, showed hardy flowers. Mr. W. H. Pattison, Shrewsbury, sent Violas and Pansies, and the Oaks Garden Sundries Company had a large exhibit. All the above received certificates of merit. The arrangement of the show, the largest in dimensions for some years, was successfully carried out by the secretary, Mr. E. R. F. Pearson, assisted by his son and a good working committee.

PAISLEY HORTICULTURAL SHOW.

THE busy manufacturing town of Paisley had its annual flower show on the 1st and 2nd inst., the exhibits being considered better, as a rule, than on any previous occasion, while in numbers they were equal to those of former years. The various rooms of the Clark Halls were fully occupied with the exhibits, and the large hall presented a beautiful sight, largely owing to four centre tables of great merit, one coming from Ferguslie, through the kindness of Mr. James Coats, the others being sent by three of the local nurserymen (Mr. D. Airdrie, Mr. F. Davidson, and Mr. J. Watson). There were also a number of nurserymen's special exhibits, which added much to the value of the show. Pot plants and cut flowers were excellent, fruit was good, and the vegetables models of their kind. Messrs. G. Mair and Son, Prestwick, well earned their first prize for Gladioli; and Mr. J. Smellie, Busby, was first with Cactus and Pompon Dahlias. Messrs. Carnegie and Son, Ayr, led in a good competition with vases of Chrysanthemums. Mr. D. Airdrie, Paisley, was first in the following classes: Six vases Carnations and Picotees, twelve Pentstemons, collection of cut flowers from the open, and collection of plants on centre table (confined to Paisley nurserymen). In a good competition Mr. Hugh Dickson, Belfast, was first for thirty-six Roses; Messrs. Smith and Son, Stranraer, being second. Mr. W. Farquharson, Perth, was first for herbaceous flowers.

Class II. was open to both amateurs and gardeners, and both showed well against each other, in many cases the amateurs beating their professional brethren. Among the most successful in the pot plant and cut flower classes were Mr. R. Robertson, Priory Park Gardens, Mr. R. McGraw, Mr. C. Pattison, Mr. R. Smith, Mr. J. Meikle, and Mr. D. Christie. In the fruit classes the leading winners were Mr. James Brown, Houston House Gardens; Mr. C. Jamieson, Castle Temple Gardens; Mr. G. Watson, Walkinshaw Gardens; and Mr. D. Christie. Mr. Brown had the best collection grown in the open air. The most successful competitor with vegetables was Mr. James Brown, Houston House, who won for the best collection of vegetables, and had also other eight first prizes. Mr. D. McPherson, Mr. J. Howie, and Mr. A. Turner were also among the successful competitors in this section. The classes confined to amateurs and to amateurs residing in the Burgh of Paisley were highly creditable to the exhibitors.

DUNDEE HORTICULTURAL SHOW.

THE annual three days' show of the Dundee Horticultural Society was held in marquees on Magdalen Green, Dundee, on the 1st, 2nd, and 3rd inst. The entries numbered upwards of 2,000, and in point of numbers and quality constitute a record. As may be expected in a district in which are employed some of the best gardeners in Scotland, the exhibits were, as a whole, of special excellence, and reflected much credit on the competitors. The society was fortunate in securing the Countess of Arlrie to open the show, her ladyship doing so in the presence of a large and fashionable assemblage. It is difficult in such an extensive show to give an idea of its main features, but it may be said that all sections showed some remarkably fine produce, gardeners, nurserymen, and amateurs all doing themselves the highest credit.

Much interest was taken in the class for a table arranged for effect, 12 feet by 7 feet. Last year the only competitor was Mr. J. Beats, Binnock, Dundee, but this year Mr. D. K.

Meston, The Lodge, Broughty Ferry, entered the field, and although he failed to wrest the honours from Mr. Beats, made a most creditable effort. All the classes for plants in pots were well filled, and the specimens were excellent as a whole. Among the leading prizewinners were Mr. R. W. Saunders, Lismore, Broughty Ferry; Mr. D. Saunders, Tay Park, Broughty Ferry; Mr. T. C. Brown, Balcairn, Dundee; Mr. G. Nicholson, St. Helen's, Dundee; Mr. G. Scott, Seathwood, Dundee; Mr. J. Bethell, Westwood, Newport; Mr. J. Beats, Mr. R. N. Simpson, The Pines, Broughty Ferry; Mr. T. Barnett, Duncairn, Dundee; and Mr. D. K. Meston. In the open classes for cut flowers the bouquets, baskets, and wreaths were very tastefully arranged, the winners of first prizes being Mr. J. Beats, Mr. A. M'Bray, Cupar-Fife; Mr. J. Bethell (for a nice collection of grasses), and Mr. G. Reid, Dowfield.

The gardeners' classes for cut flowers were most attractive, and this was one of the best departments of the show. Mr. J. Fairweather, Arlrie Park, had the best twelve varieties of Sweet Peas, Mr. Bethell being a good second. Few classes in this section created so much admiration as that for an artistic display of hardy flowers and foliage from the open, shrubs excluded, Mr. J. Bethell winning with a most tasteful arrangement of good flowers. There were no entries for show Dahlias, but Mr. H. Rutherford, Brechin, was first for twelve and also for six Cactus Dahlias. Mr. J. Dick won for Pompons; Mr. D. Halley, Strathmartine Road, was first for twelve Carnations, distinct, and Mr. R. N. Simpson was first for twelve vases of Carnations. Mr. R. N. Simpson had the best hardy herbaceous flowers, Mr. J. Bethell being second. The other classes cannot be detailed.

In the classes for caryophylls and florists, Messrs. D. and W. Croll, Dundee, were first for twenty-four Roses, Hybrid Perpetuals or Hybrid Teas, and for twenty-four Teas or Noisettes; Messrs. J. Simpson and Sons being second in each case. Mr. M'Ar, Crieff, and Mr. W. Farquharson had respectively the first prizes for twenty-four Cactus Dahlias and twelve bunches of hardy flowers. Fruit was splendid in almost all the classes, and the competition keen. Mr. J. Beisant, Castle Huntley, had the best dessert-table, decorated with flowers and foliage and sixteen dishes of fruit; Mr. J. Beats making a good second. Mr. W. Bennie, Murie, Errol, had the best collection of Apples; Mr. G. Scott that of eight dishes of fruit; and Mr. J. Farquharson, Kinfauns Castle, the best collection of hardy fruits. The leading exhibitors in the Grape classes were Mr. D. Mackenzie, Mr. G. Scott, Mr. J. Kinneir, Mr. J. Beisant, Mr. W. R. Whitecross, Mr. D. Hendry, and Mr. T. Butchart.

The vegetables were very fine, the Corporation Cup for a collection of twelve kinds being won by Mr. W. Harper, Tulliehelton, with a collection of superb quality. Amateurs showed well, and the Corporation Cup for a display of cut flowers and foliage in vases from open border was well won by Mr. D. Duthie, Loches. Space will not permit of more than a summary of the nurserymen's exhibits. Noticeable among these were the Apples in pots from Messrs. Storie and Storie, Messrs. W. P. Laird and Sinclair's miscellaneous exhibit, Messrs. Thorne and Paton's floral designs, Messrs. Dobbie and Co.'s Roses, Dahlias, and other flowers, arranged in their usual fine style; Mr. John Forbes (of Hawick) cut flowers, largely florists' varieties; Messrs. G. Mair and Son's Gladioli, and the exhibits of Messrs. D. and W. Croll and Messrs. J. Simpson and Sons.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 5, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Names of plants.—J. B.—Neither of the specimens sent is Dandy. That in flower is Mangle's Variegated, which often blooms, and the small pieces are Mme. Salleron. —*Alfred James.*—No. 1 is a very deeply coloured form of Salvia Horminum. No. 2 is Phytolagus capensis.

Names of fruit.—*Bloxham.*—1, Duchess of Oldenburg; 2, Devonshire Quarrenden. —*F. T. Medhurst.*—The variety is Lord Suffield, and it is not unusual for this Apple to bear twin fruits. —*C. E. F.*—3, The Queen; 4, Ecklinville Seedling; 5, Wealthy; 6, Warner's King, unusually well coloured. —*P. L. C.*—1, Plum Denbigh Seedling; 2, Apple Gravenstein; 3, Apple Yorkshire Beauty.

Japanese Maples.—(H. W. J. Tones).—You could hardly do better than plant beds of these to give colour in your garden. We question if there are any more useful foliage trees than these, and it is surprising that they are not more generally grown in gardens to give that touch of colour so often wanting in borders and shrubberies. The variety of colouring is great, the leaves beautiful in spring, summer, and autumn, and the trees are quite hardy. The open garden, however, is not the only place suitable for them, for they do well grown in pots, and are then extremely useful for corridor and conservatory decoration. No other plants give the same effect or provide a brighter contrast to the things around them. Plants in pots are useful, for if the latter are sunk in the ground the graceful tops do away with that flatness of surface that too often exists in flower-beds during summer.

Cherries in pots. (K. S. W.).—Cherries grown in pots and forced slowly are a great success. There are many varieties suitable, as fortunately most of the good ones succeed when grown under glass. We may mention Early Rivers', Bigarreau de Schreken, Frogmore Early Bigarreau, Bigarreau Jaboulay, Archduke, Royal Duke, May Duke, Nouvelle Royale, Florence, Emperor Francis, and Bigarreau Napoleon. With reference to stopping the shoots of the trees due regard must be had to the variety, some grow much more compactly than others and need less stopping. You must repeat every season if your trees are in small pots, taking away carefully a portion of the outside of the old soil with a pointed stick, cutting away very thick roots and repotting just as the leaves are turning colour. Use a good loam with such stimulants as bone-meal. Pot very firmly. Many growers plunge their trees in the open—in any case the roots need protection. The temperature should be as low as possible at the start, give plenty of air when the trees are in bloom, and when the fruits are set slightly increase the temperature. Give 50 at night, 10° higher by day; as the fruits swell give 55° at night and a corresponding rise by day. Syringe twice daily, morning and afternoon, fumigate freely to keep clean and feed well; also mulch the trees with manure if the pots are small, and as the fruits ripen keep the atmosphere drier.

The Loganberry. (W. N. BOLAS).—We recently illustrated this fruiting plant and gave full particulars about it. However, we now repeat them. This plant is a hybrid between a red Raspberry and one of the finer varieties of Blackberry. The fruit is much like an enormous Raspberry in appearance, but with a darker bloom and larger shape, the flavour being very good though somewhat sharp. The fruits are produced on the growths of the previous season in the same way as the Raspberry; it should be cultivated much on the same lines, cutting out the old wood yearly in autumn and training the long shoots, which are thrown up from the base, by tying them to those of the next plant, about 5 feet away. Rich mulching will enable the fruits to swell freely. This mulch should be laid down in March when the fresh growth begins, the fruit being produced in June before Raspberries are ripe. The thorns of the Blackberry are fortunately absent from its stems, which are covered with small, red spines. The foliage is handsome and vigorous and keeps clean. There is no doubt that when better known this plant will become more extensively grown. It is, however, not possible to propagate it by seed, as this has a tendency to revert to the original parent types, so that it cannot be relied upon to produce the true Loganberry, which should be propagated by suckers.

Single Scotch Roses. (W. J. DORR).—Yes, you ought to plant these in September, say towards the end of the month. They generally flower at the end of May; they are lovely little Roses, and if suitably placed away from the many flowering shrubs out at that period their beauty is much appreciated. The majority of single Roses are produced on large, straggling bushes, but in this case the neat compact habit lends additional attractiveness to the showy but fleeting blossom. If the persistent nature of the new Rambler Leuchstern could be imparted to the single Scotch Roses, they would gain greatly in value if their dwarf character were not altered. From a number of seedlings it is possible to pick out many decided colours, but the majority will come white, so that it is best to get bushes to colour. They vary from lemon yellow to buff and pink, and from pale rose to rich rosy red, almost crimson. Some have quite a white centre, giving the flower a very pleasing appearance. A single bush will in a short time become 3 feet or 4 feet thick, so that you can easily imagine the beauty of such a bush planted in a conspicuous position. The earliness of the single Scotch Roses makes them invaluable.

Standard semi-double Roses. (P. J. WALKER).—At no time is the true decorative value of the standard semi-double Rose seen to better advantage than when grown in a pot in a cool house. A beautiful variety that does well is Mme. Pernet Ducher, one of the best Hybrid Teas. A three year old plant makes a charming display. This Rose is almost equal in growth to its near relative Gustave Régis, which also does well under glass. Every garden would be the better for standards of such glorious semi-double Roses as Grisi in Tepitz, Mme. Laurette Messimy, Killarney, Bardon Job, Queen Mab, Enchantress, &c., and then we might hope to see some fine, well-proportioned heads, some drooping, others spreading, but all free from artificiality. Whether in pots or grown outdoors, this type of Rose pays for good culture, and though their blossoms are thin, if given liberal treatment they much improve; in fact, so great is the change that one hardly recognises them when compared with poorly-grown plants. New wood should be encouraged as much as possible, and the knife freely used in thinning the centre of the heads, but the previous year's growths, if hard, may be retained any length, and the longer the better.

Diseased Rose and Peach foliage. (K. A. E.). The Rose foliage is attacked by what is known as "black blotch." This fungus is extremely prevalent this year, and we can only conclude it is owing to the excessive wet of last season. We have noticed these diseases of the Rose are far more prevalent upon plants procured from the Continent than upon home-grown ones. It is rather late now to apply a remedy. We should advise you to have the leaves collected as they fall and burn them. Next season, as soon as Roses are pruned, spray the plants well with Bordeaux mixture. Repeat the spraying in May, and again in July and August. If this be done you will considerably check fungoid diseases, if you do not absolutely cure them. The Peach foliage is attacked with Peach leaf rust. It is a very common disease, and we think you need not trouble much about it, as it does not affect the wood. Spraying with Bordeaux mixture would undoubtedly check the rust, only that it should be done much earlier in the season. The spraying of trees can do no harm, and it will certainly accomplish a considerable amount of good. As the fruits upon your Peach trees are not developing well, perhaps the roots are in an uncongenial subsoil. We should advise you to let your gardener just raise the plants in October and then set them

A FRUIT STORE: THE INTERIOR IS FILLED WITH ORR'S TRAYS.

back again in the same positions. This has a tendency to encourage fibrous roots near the surface, and it moreover prevents the trees from making such coarse growth, as they are very liable to do if unchecked.

Sweet Pea Lord Rosebery (J. E. USHERWOOD).—It is not very unusual to find Sweet Pea flowers with double "standards," as appears to be the case with those sent. It is much more unusual to find the "wings" double also. The variety Lord Rosebery is liable to variation in colouring. The doubling of your flowers, and of others we have seen this year, is partly due to the continual watering and perhaps feeding that the hot weather has made necessary.

Winter-flowering Violets (W. SWELLS).—The general method adopted is to select rooted runners of the plants which have done flowering, transplant them to the kitchen garden or some border, where they remain during the summer months, afterwards to be transferred to their flowering quarters. Propagation may be effected by inserting cuttings early in May in boxes, filled with a mixture of loam, leaf-mould, and some sand. Place the boxes in a cold frame, where, if judiciously shaded and syringed, they will root in about three weeks time. After they have made enough roots to stand exposure the boxes may be put outdoors in a sunny spot, so as to ensure the growth being matured. No transplanting out of doors will be necessary. Plants treated in this way do not produce runners to the extent that those planted outdoors generally do; besides, being entirely supported with young or new roots, the plants soon grow after being transferred to their flowering quarters, and are not so susceptible to the ravages of red spider as those propagated by division of roots often are. The beginning of September is the best time to plant in frames. The soil should be a good loam, with the addition of some material from a spent Mushroom bed. A dusting of soot will help to remove any wireworms which may be in the soil.

Peach Stirling Castle (S. W. FORD).—You need have no hesitation in planting this variety of Peach. It is one of the best we have, and is equally suitable to the amateur or professional gardener. It has now been in cultivation many years, and both out of doors and under glass has proved itself of the highest merit. Of medium size, delicious flavour, well coloured and prolific, it is indispensable to every collection, whether large or small. For forcing it is especially suited, and it succeeds well in a second early house. It has the valuable property of not dropping its buds, as some varieties when forced are very liable to do, and it also comes into bloom quickly with very little forcing. An additional advantage possessed by this Peach is that the stamens of the flowers always carry plenty of pollen, and all who have to do with the early forcing of fruit trees will know how a variety with this characteristic is appreciated, for a great drawback to many early forced Peaches and Nectarines is their deficiency of pollen, making it almost impossible to obtain a satisfactory crop of fruit. Stirling Castle Peach well deserves to be cultivated if only for the quantity of pollen it produces, as this can be made use of for the fertilisation of other shy pollen-bearing varieties.

Grafting Ceanothus Dampieri (J. W. CROSS).—The grafting of *Ceanothus Dampieri*, in order to overcome the difficulties of its cultivation, is by no means a recent innovation, for as long ago as 1868 there were some good flowering plants at Kew that were obtained by grafting this *Ceanothus* on specimens of *Swainsonia galegifolia*. They attracted much attention at the time, and the lead was followed in several instances, but it soon died out. At that

period some cultivators failed in the grafting process owing to scions being taken from flowering plants instead of using young seedlings. At Kew *Ceanothus puniceus* was also used as a stock, but the best results were obtained on the *Swainsonia* grown in a suspended basket.

Muscats Grapes failing (W. J. DAWSON).—Your Muscat Grapes are both shanked and scalded; the latter can be easily remedied, but the former is more difficult. The scalding at times appears to be due to bad ventilation or bad glass, and, also, if the foliage has had free play for a time and is then stopped close, and if the vines are near the glass the sun scalds the berries. Muscats scald sooner than Hamburgs or other Grapes; indeed, we think Madresfield Court is one of the worst in this respect. Cover the glass thinly with whitening and milk for a short time, as that will arrest the scalding. You ask if the spot is a disease. The scalding, of course, is not, but the soft imperfectly-finished berries with a dried-up footstalk are certainly the result of disease, but one that need not alarm you, as it can be checked if taken in hand thoroughly. It is often brought about by over-cropping the vine in a young state. Vines when young crop so freely that they are often left to mature far too many bunches. Now the root-action of the plant is not strong enough to support such a heavy crop. Vines that are too heavily cropped do well for a time, then shanking or spotting of the berries commences, and the stalks shrivel before the berries are ripe. Muscat of Alexandria is more subject to this than others. The same thing occurs in poor, thin, porous soils. You may have a heavier crop this season than usual; if so, we advise you to allow the later laterals to grow freely. Cut the bunches as soon as the grapes are ripe. Feed the vines freely, and give them liberal treatment for some time. Shade the house lightly, and mulch the surface roots with good manure. Crop lightly next year.

Alterations in Rose garden (LONDONER).—As you are not quite satisfied with the arrangement of the varieties in your Rose garden, you could without any serious disadvantage replant the beds in October or November next. We are not surprised that you do not care for Francis Dubreuil. It is not at all an effective variety in the garden, however beautiful its individual buds may be. They are very beautiful when the plants are well established, but not quite fitted for garden decoration. Grand Duc de Luxembourg we feel sure you would like if you gave it another trial. Its colour is delightful. You ask us to suggest five other kinds to add to your rosery, and we gladly do so. The five would be Liberty, Marie van Houtte, Prince de Bulgarie, Corallina, and Anna Olivier. The following would also be excellent if you do not approve of those suggested, viz., Mme. Jules Grolez, Comtesse Festetics Hamilton, Mme. Antoine Mari, Morning Glow, Kaiserin Augusta Victoria, Mme. C. P. Strassheim, Mme. Edmee Metz, and Lady Roberts. As you desire us to offer suggestions as to planting your garden, we may say we should arrange the sorts as follows if we were about to plant it again: The centre beds, Dr. Grill, Anna Olivier, Prince de Bulgarie, and Marie van Houtte. Then, taking the half of the rosery by the trellis, we should plant Caroline Testout and Mme. Hoste in the two end beds near the trellis, Mme. Lambert and G. Nabonnand in the two oblong beds, Mme. Ravary and Maman Cochet in the large oval beds, and Liberty and Lady Battersea in the small circular beds. The corresponding half of the rosery would be planted thus: End beds, La France and Corallina; oblong beds, Mme. Abel Chatenay and Caroline Kuster; large oval beds, Mrs. E. Mawley and Captain Christy; small circular beds, Marquise Litta and Marquise de Salisbury.

Single Sunflower (ERNEST MOON).—You have the choice of two good kinds, that with liberal fare and good culture generally will more than replace the Harpalium. The kinds referred to are both varieties of the perennial Sunflower (*Helianthus multiflorus*), and are known respectively as H. multiflorus (simplex), 4 feet high, or rather more when established, of bushy habit, free growth, and abundant flowering. The flowers are rich yellow, 3 inches or more across. The plant is a very profuse bloomer. No. 2 is H. m. grandiflorus, a much larger, paler yellow flower, very fine in every respect if less abundant in flowering. This variety is 5 feet high, and more in especially good soil. If you desire to get the best possible return in vigour and flowering you should replant these things every two years, preferably in spring, as growth is starting anew. You will also find a free division of the rootstock equally beneficial, and if to these things are added generous cultivation you will be well satisfied in the end. The two plants named are quite distinct, not only in colour, but in the form and character of the flower also.

Trailing Campanulas (W. H. STEVENS).—There are several species and varieties among the trailing members of this genus that, from their exceeding beauty and freedom

of flowering, are worth special attention. At this season of the year, for example, we have none too many really good free-flowering trailing plants in the rock garden, that is, of those kinds which are regarded as being there permanently, so that the free use of the more decorative *Campanulas*, and in particular those of trailing habit, should be indulged in. It often happens, however, that these plants are by no means satisfactory in the position accorded them, which is generally a sunny and exposed one, and therefore hot and dry. Now this is quite the wrong position at the outset, and it can hardly be expected that a plant preferring a certain amount of shade can do well in a position quite the reverse.

Le Chrysanthème: Transactions of the Massachusetts Horticultural Society; Bulletin de la Société Nationale d'Acclimatation de France; Bulletin of the Agricultural Experiment Station, Rhode Island; Board of Agriculture Pamphlets on "Feeding Poultry"; Boletim da Real Associação Central da Agricultura Portuguesa; Bulletin of the American Association of Park Superintendents.

TRADE NOTE.

ORR'S STORING TRAYS.

ORR'S STORING TRAYS are really portable shelves for the purpose of sorting, storing, handling, or exhibiting fruit, bulbs, seed Potatoes, or any light goods. It is only claimed for the trays that they are a mechanical means of handling fruit from the tree, of packing for market or until wanted for home use, but in these uses alone they are most valuable to the fruit grower. The stock tray, considered to be the most convenient for handling and storing fruit, bulbs, &c., weighs only 6lb. and measures 28 inches by 25 inches by 5 inches, the floor being made of rounded slats. The advantages of this system are: Ease of grading, of picking out ripe or decayed fruit, of packing for market; handling and bruising reduced to a minimum; quantities readily estimated, and economy of space and cost of fruit room. If the trays are taken to the trees the fruit can be graded directly on to them, where there is light and room for the operation, and the least amount of trouble involved. The construction of the floor of the tray (rounded slats) while obtaining lightness for it, and free ventilation for its contents, also checks any tendency for them to roll, so that fruit can be carried safely and conveniently on them. From 30lb. to 40lb. of fruit can be put on a tray. The trays are well made and finished, as with ordinary care they would last any number of years. Extreme accuracy in their manufacture is necessary, as each tray is composed of thirty-three parts, put together with sixty-five nails, and has when completed to be the exact duplicate of any other one, on to, or into which it may have to fit. Though perhaps costing more than fixed shelving, the compact way in which fruit

A PAIR OF ORR'S STORING TRAYS.

can be stored admits of a minimum cost for the fruit room itself. These trays are manufactured and sold only by Mr. John P. White, The Pyghtle Works, Bedford.

THE GARDEN

No. 1713.—Vol. LXVI.

[SEPTEMBER 17, 1904.]

THE COMING ROSE SHOW.

THE exhibition of Roses that will take place on Tuesday next under the auspices of both the Royal Horticultural and National Rose Societies is in the nature of an experiment, and we fear the display will not prove so interesting as would have been the case if the show had taken place last year. Sunny days there have been, but cold nights and drenching rains have held the buds in check and sullied the open flowers; at least, this is our experience, gained by visiting several gardens in which Roses are largely grown.

But, in spite of unkind days just before the show, we shall no doubt see much to interest and admire in the Roses at the Royal Horticultural Hall next Tuesday, and probably a fairly keen competition. If the show has no other effect than of stimulating hybridists to bring Rose beauty into the garden in August and September, and even into October, it will have helped forward an excellent work.

Climbing Roses that will flower in autumn are few in number. A beginning has been made with such hybrids as Dorothy Perkins, which is, at the moment of writing, covered with its bright rosy flowers, and as many as possible of this type in other colourings will be as welcome as the fairest sorts of June and July. The garden in autumn has changed its complexion. Bedding plants which rot with the first breath of frost no longer dominate, but in their place clouds of Starworts, Lilies, Sunflowers, Golden Rods, Kniphofias, and other flowers fill the border and bed with a warm colouring, and not least in the throng is the Rose, which in its many variations, when the weather is reasonably pleasant, will bloom with great freedom. Those who have quiet sheltered gardens filled with Roses will be the most successful on Tuesday. We know many of these fragrant spots, where the flowers are dyed a deeper colour in September, and are as profuse as in full summer. Many a faultless flower will be gathered from Marie van Houtte, Anna Olivier, Caroline Testout, Augustine Guinoisseau, and the Chinas and Hybrid Chinas for next Tuesday's exhibition, which will be even more instructive than the great display in early July in the Temple Gardens. A Rose that will bloom well in autumn may be considered a good garden variety, and not merely of exhibition value, and for that reason the would-be rosarian or seeker after varieties not yet acquired should be busy taking notes.

The National Rose Society during the past few years has displayed a praiseworthy vigour, and the establishing of this show is the latest development. We hope that it will be successful, and, even if it is not this year, there is no reason why the exhibition next autumn should not prove so. Summer shows are not always a success, and an opportunity is offered to all who love the Queen of Flowers to help the National Rose Society by attending the first autumn display, and thus give their support to a departure which deserves encouragement.

VALUELESS APPLES.

It may be stretching a point, perhaps, to say that any Apple is absolutely valueless, because even the most inferior and insignificant-looking fruits can be put to some purpose; but we mean by valueless Apples those which fetch little or nothing in the open market, and in seasons of comparative plenty, like the present one, are not worth the trouble of picking with the object of selling them for culinary purposes. Covent Garden is not the place to find the examples referred to, because, in spite of the fact that all the produce sent there is not above criticism, people know that rubbish does not meet with much favour in the central market of the Metropolis. Really to understand what is meant by valueless Apples one should get away from London, and attend one of the local fruit markets in the west of England; or, better still, make a tour through the orchard land in that part of the country, and note the kind of fruit which many of the trees produce. Never is the importance of growing good fruit of high class recognised varieties more clearly emphasised than in a season of plenty, for facts then show that good fruit will sell, but inferior stuff is valueless. Recently I have had opportunities of attending some of the fruit markets in one of the finest Apple-growing districts in the country, and have seen a variety of produce offered for sale. It is only fair to say that some of the fruit is good, and though the best always commands the highest price one sees such strange mixtures of bad, good, and indifferent spread out before the auctioneer, that one gathers the impression that the good samples are presented with the object of helping out the second and third rate ones. It is evident that this mixing of all sorts does not have a good effect on the market, for though the poor Apples fetch quite as much as they are worth, the presence of poor produce has an effect on the sale of that which is much better. When a market is full prices rule low throughout, even though one-half of the fruit may be good and the other half poor, and I think that the presence of a large percentage of the latter is responsible for really good fruit being sold at a lower figure

than it would be otherwise. The rank and file of Apple growers, too, have a good deal to learn about the importance of grading, for not half enough attention is paid to this matter. Here, too, one may observe an obvious want of system, for those growers who do grade their fruit, and present even samples of distinct varieties, do not get the reward they should for the extra care they take, because in the rush of the auction the difference between one or two graded lots amid a score or more of all sorts and sizes is not noticed. When only a few odd lots in a big fruit auction are graded they certainly fetch a little more money, but it is the buyer who really gets the benefit. What is wanted is more co-operation amongst producers. Instead of every grower sending his fruit into the market just as it pleases him, if the Apple growers in a district would agree to act in unison, and send nothing but good graded samples, the tone of the auction would be raised, and the better prices obtained all round would more than repay for the slight loss which might be incurred through having the small fruit left on hand.

It is generally admitted that there are plenty of home-grown Apples in the country just now and prices are ruling low, but it is quite likely that a month or two hence English fruit will not have to go begging, and then the Americans will step in with their barrels of nicely graded samples, and we shall hear the old story again about foreign competition. One has only to attend local fruit sales to understand the reason why British Apples are often so scarce only a few months after they are apparently so plentiful, because it may be seen what little attention is paid to systematic storage. The one idea of the British farmer who has an orchard of Apples seems to be that of getting the fruit into the market at once, so as to wipe his hands of it, and there is no doubt that the profitable sale of Apples which must be disposed of at this season is spoiled through long keeping, late varieties being rushed into the market along with them. The other day I was surprised to see a really fine lot of Blenheim Orange offered for sale next to a lot of Lord Suffield. The former sold for a price that was heart-breaking to the grower, but if he had kept the fruit till towards Christmas he would have made money of it. It is an indisputable fact that British orchards do not supply the million with nearly so many Apples as they ought to do, and one reason is that growers rush all their fruit into the market at once instead of holding back the varieties that will keep till people ask for them.

From the fruit in the market let us turn to the orchards, and there may be found quite a plethora of what we call valueless Apples. Growers may contend that they are not valueless, because they can be utilised in the cider-mill, but if these scrubby, inferior, nameless, and unsaleable varieties were replaced by good sorts, the best examples could be sold for table use and the cider-mill might claim the seconds

and thirds. In the majority of orchards in the west of England may be seen—in some cases a few, and in others many—large old trees, the fruit from which is never sent to the market, because it possesses no value there, and it hangs on the tree till it falls naturally and is ground up for cider making. Cider is, of course, a wholesome beverage, and as a home industry the making of it is worth encouraging, but the varieties of Apple we describe as valueless are not even cider Apples, but they are utilised for that purpose, because they will make a liquor of some kind and are fit for nothing else. If people are to be persuaded to drink cider it must be good and should be made of suitable fruit, not by grinding up any kind of rubbish such as is done in many cases at the present day. We hear a good deal about the neglected, overcrowded state of the trees in the home orchards in this country. Alas! it is all too true, as a tour through any Apple-growing district proves, but in many cases we are convinced that a radical sweep away would be a better course than attempts at renovation. In the case of good saleable varieties it would doubtless pay to clean and feed the trees and thin out the superfluous wood with the object of getting better fruit, but what is the good of spending time and money over such operations in the case of trees the fruit from which possesses no market value?

Old fruit trees in country districts are like old customs—they die hard, and, though not given to pessimism, I look for no great improvement in old orchards so long as the existing trees remain, for hundreds of them are too far advanced for heading back and regrafting, and there is a natural and deeply-rooted aversion towards cutting a tree down while there is a spark of life left in it. In consequence of this the good varieties will continue to be picked and sold, while the valueless Apples will still encumber the earth and glut the markets. There are hopes for the future, however, because the fruit growers of this generation, though reluctant to abolish existing trees, are alive to the importance of good varieties, and any man who plants an Apple tree to-day may be trusted to secure a good variety. G. H. H.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

September 20.—Royal Horticultural Society's Committees meet; National Rose Society's Autumn Show.

October 5.—National Chrysanthemum Society's Show at Crystal Palace (two days).

October 12.—Royal Botanic Society's Show.

October 25.—Croydon Chrysanthemum Society's Show (two days).

November 1.—Bournemouth Chrysanthemum Show (two days); Brighton Chrysanthemum Show (two days).

November 2.—National Chrysanthemum Society's Show at Crystal Palace (three days); Southampton Royal Horticultural Society's Show (two days); Highgate Chrysanthemum Show (three days); Lowestoft Chrysanthemum Show (two days); Portsmouth Chrysanthemum Show (three days).

November 3.—Weybridge Chrysanthemum Show; Colchester Chrysanthemum Show; Forest Gate Chrysanthemum Show (three days).

November 4.—Windsor and Eton Chrysanthemum Show; Battersea, Clapham, and Wandsworth Chrysanthemum Show (two days); Hinckley Chrysanthemum Show (two days).

United Horticultural Benefit Society.—The eighteenth annual dinner of this society will be held at the Holborn Restaurant (Venetian Chamber), High Holborn, W.C., on Wednesday, October 12, at 6.30 p.m. Mr. W. A.

Bilney of Weybridge has kindly consented to preside on this occasion. The committee hope that all honorary and benefit members and their friends, who can possibly do so, will endeavour to attend and give the chairman their hearty support, and so help to make the dinner a thorough success as in past years.—W. COLLINS, *Secretary*.

The British Gardeners' Association.—The official Journal of the Department of Agriculture, Belgium, contains an article entitled "Le Groupement des Jardiniers Anglais," by M. Louis Gentil, Curator of the Botanic Gardens, Brussels. It is largely a translation of the history and objects of the British Gardeners' Association, full particulars of which have been published in THE GARDEN. M. Gentil is in full sympathy with the association, and thinks it cannot fail to do good. He deplores the want of cohesion among the horticultural societies in Belgium, and says "we have no powerful central organisation." M. Gentil believes that Belgian gardeners of all classes will watch the progress of the British Gardeners' Association with keen interest.

Chrysanthemum trials at Tamworth.—One of the chief events of the year in connexion with the popularising of the early-flowering Chrysanthemums is to take place on Saturday, the 24th inst., at Tamworth. Mr. William Sydenham of Bolehall House has in recent years devoted considerable attention to these plants with the object of showing their value in the hardy flower garden from August onwards. In his efforts he has been singularly successful. Much useful information has been acquired, and since disseminated by means of conferences, exhibitions, &c., and each succeeding season finds Mr. Sydenham continuing his work. The trial this year is a thoroughly good one, each variety being seen in proper form and condition. The plants are arranged in alphabetical order, thus simplifying an inspection of the complete collection. Some 300 were planted in May, and most of the plants have made very large and bushy specimens. For some weeks past many of the sorts have flowered profusely, and by the 24th inst. many will be at their best. The opportunity is unique, and those who can spare the time to visit the trial and exhibition to be held on the same occasion cannot fail to profit by doing so. Tamworth is served by the London and North-Western Railway and Midland Railway, and the stations are some ten minutes' walk from the trial grounds. A small charge is made for admission, and the sum thus derived is handed over to the Society for the Prevention of Cruelty to Children.—D. B. C.

Japanese garden at the World's Fair.—After a visit to the Fair one cannot but be impressed by the activity displayed by the Japanese. Wherever they have made an exhibit it ranks among the best and attracts great attention. Although their efforts have been directed mainly along industrial lines, yet much has been done from a decorative standpoint, the most important feature of which is the Japanese garden, situated at the western end of the cascade territory on a small hill 40 feet to 50 feet high. It is about three or four acres in extent. With its elevations and depressions this spot is admirably adapted for the purpose, and was selected by the Japanese landscape gardener as the only suitable situation in the grounds. The garden is a replica of a portion of the Imperial Garden of the Mikado, and is the work of the Imperial gardener, Mr. Yukio Itchikawa, whose ability is shown by the tasteful arrangement of the grounds. The entrance to the garden is rather imposing. The gates, which are always open, are very large and massive, and are decorated with the Royal crest. The main walk turns to one side, leading up to the entrance of the Japanese commission house and to the reception hall, which is just beyond the crest of the hill. The highest point in the garden is almost in the centre, and is crowned by a group of staminate *Cycas revoluta*, planted out in the open ground, some with stems 5 feet high. The really pleasing feature of the garden is the lake at the foot of the hill. It is edged with porous limestone rock, and suitably planted with a variety of typical Japanese plants. In the centre of the broadest part of the

lake is a small island, connected by two artistic bridges. A large Japanese Maple (*Acer palmatum dissectum*) is planted at one end of the island near a stone garden lantern, and produces a fine effect. A ford of stepping stones gives a passage across the narrowest part of the lake. The treatment of the banks is especially pleasing. At one end the bank is quite steep, and is faced with porous limestone rock, from the top of which flows a miniature cascade. Numerous pockets or openings in the rock admit a number of Azaleas, dwarf Bamboos, and a number of well-known Japanese shrubs, including several plants of *Nandina domestica*. At the top of the bank overhanging the cascade is a large trained specimen of *Wistaria chinensis*, about 4 feet high, with a stem several inches thick. Considerable interest is also centred in a large and varied collection of Chrysanthemums, which are planted in the open ground, behind the reception hall. Japanese Chrysanthemum culture is well illustrated, and they are looked forward to by all as some of the best varieties in Japan, which have never been exported, are contained in the collection.—Geo. E. McCURE in *American Gardening*.

Prizes for model gardens.—Through the kindness of Captain Houldsworth, Goodham, Ayrshire, prizes were offered at the annual flower show held at Symington, Ayrshire, for the best model gardens. The competition was confined to the parish of Symington, but there was a keen competition, much interest being taken in the class. The prizes were adjudged as follows: First, Mr. James Landsborough; second, Mr. Thomas Niven; third, Mr. James Love. The models were generally well planned and arranged, and creditable to the competitors.

Zephyranthes × Ajax (hort. Sprenger).—I believe that this is the first hybrid *Zephyranthes* raised in gardens. I saw it flowering splendidly in a border in a garden on the Vomero Hills, near the old Castell, St. Elmo. The parents are *candida* × *citrina*, and the cross is exactly intermediate. The leaves are a little broader than *candida*, bright green, and produced in spring; the flowers appeared here in midsummer and continued till October. They are canary yellow colour, often tinged with red outside on the top, stamens and style are also yellow. It comes quite true from seed, which is freely produced. The flowers open well only in sunshine; when closed they are very similar to a *Crocus*. In every way this *Zephyranthes* is a welcome addition and well worth cultivation. It is a good pot plant. We may also hope to hear about other hybrids next year, as I saw some promising seedlings.—W. MULLER, *Naples*.

The Loganberry.—I am very pleased to see so much interest taken in the Loganberry, as it is a valuable fruit, being exceptionally free-bearing, and the quality is excellent, a piquant flavour which I esteem when the fruit is eaten fresh and also when it is cooked. I have several plants of it, and intend to plant more in the autumn. The growth made since they were put in last April is tremendous, the shoots being strong, leafy, and of great length. I have not tried The Mahdi or any of the other new Blackberries, but if they are more prolific than the Loganberry they must be very good indeed. My plants are against a rough Oak paling, and have thrust everything else aside in their hurry to cover every inch of wood. I am not quite certain how to prune it. Will someone advise me?—T. E.

Propagating the Loganberry.—I see on page 112 (the 13th ult.) in THE GARDEN that Mr. G. Wythes says that the Loganberry should be propagated by suckers, the same as the Raspberry. The way we propagate it here in British Columbia, and also the method by which it is increased at its home in California, is by slips. Every slip will make a strong plant, and I have often got five or six from one shoot. Often the shoots throw out offshoots or little branches, and every one will root if properly layered. The Loganberry is being planted very extensively on the Pacific Coast. It does remarkably well in this dry climate.—G. A. KNIGHT, *Mount Tolmie Nursery, Victoria, B.C.*

Ceanothus Indigo.—The various garden forms of *Ceanothus* make useful and showy plants for beds or groups in shrubberies, as they have a long flowering period, which commences in July and lasts until October. Among the many varieties the flowers of several are of various shades of blue, and the one under notice is of that number. In the case of most, however, the colouring is very pale, but with Indigo it is deep, making it perfectly distinct from any other; in fact, it is the most showy of all. Like the other garden *Ceanothus* it grows well in rich, loamy soil, and does best if spurred back in spring to within a few eyes of the old wood. Should very sharp frost set in during winter it is advisable to scatter a little Bracken or hay among the branches. So far it is not well known, as it has not been in commerce very long.—W. D.

Tamarix Pallasii var. rosea.—Under the name of *T. hispida* var. *estivalis* this lovely autumn-flowering shrub was sent out a few years ago. It is the most showy member of the genus, and is likely to become very popular in gardens. *T. Pallasii* is a native of Eastern Europe, and is also found in Afghanistan. It grows to a considerable height and flowers in August. The variety is still in a small state, the largest plants at Kew being only 5 feet or so high; these, however, have been cut fairly hard back on two occasions. The foliage is very pretty, being of a greyish shade. The flowers are pink and borne in dense, stiff axillary racemes along the greater part of the current year's wood, a branch forming one long panicle of blossom. The chief item towards its success appears to be to obtain good strong annual branches, the flowers not being so good from the weaker shoots. It is necessary to give rich soil and to prune the branches back fairly hard in spring. Flowering begins early in August and continues through September. At Kew a bed of it may be seen in flower near the Succulent House.—W. D.

Onopordon polyccephalum (sp. nov.).—One of the finest Thistles I have ever seen is now flowering under this name. It was sent in the form of seeds from Turkestan two years ago, and from the first appearance of the seedlings it was apparent that this species would prove distinct on account of the formidable armour the leaves carried. Spines, quantities of them, 1 inch or 2 inches long, rendered handling the plant a difficult matter, and as the thirty to fifty headed inflorescence appeared from the beautiful rosette of leaves the spines became 6 inches long and even more numerous. When in full flower the plant resembled an enormous candelabra, every flower-head was 5 inches across, and coloured a rich pink-purple, really a bright colour very showy. It is a stately plant that one could use isolated in a small bed or in borders. I have seen all the *Onopordons* known to cultivation—*Acanthium*, *bracteatum*, *illyricum*, *Sibthorp's* species, and *tauricum*, but none of them is so handsome as this newcomer. The silver whiteness of the leaves and stems, the remarkable number of spines, and the handsome flowers, together with a stately yet compact habit, render this the most striking of Thistles.—G. B. M.

Herbaceous Pæonies.—Those who propose to move or restock herbaceous Pæonies should choose the present time, for the tubers are making roots that help the buds to develop during early winter, and these make all the difference between success and failure to flower the plants well next season. The dry weather of the past three months has ripened growth prematurely fully three weeks before the normal season, and buds are weak, but with the rainfall that now appears general all over the country there should be no difficulty in moving Pæonies with perfect safety so that they will flower next season. They all delight in a rich soil made tolerably firm, and one should give them plenty of headroom so that the stems may become strong, thinning the buds freely if they appear unduly numerous at planting time to direct the plants' energies to a few of the strongest leads. Propagation may be carried out now with strong stools, each tuber with a firm bud attached will grow well, if it does not flower, in the following season. A better

method of increase, that does away with the necessity of lifting the stools and breaking them up, is likely to commend itself to the amateur, who would be sorry to lose flowers for one season. This is to cover the stools with 8 inches of light soil made firm; growths will push through this in spring readily enough and will flower well, but in September following the resting buds will be found on independent stems 6 inches long and with a mass of roots at their bases. These should be detached and replanted forthwith, and the old soil cleared from the stools to admit warmth, when they will develop many buds hitherto latent, and which they always have in reserve. These will flower in the course of the season, and the amateur finds himself still in possession of vigorous flowering stools and a colony of young plants besides. The flowering strength of the stools is but little impaired, but a vigorous thinning of several weakly growths may be necessary in the second season.—G. B. M.

Montbretia rosea.—Vigorous clumps of this fine old plant are always a source of pleasure in August and September, and although there is the possibility of many new hybrids surpassing it in colour effect, it will always be valued for its freedom and graceful yet vigorous habit. Its bulbs are very large for a *Montbretia*, more resembling *Crocus* than anything else, and each produces several stems, which are generally eight to ten-branched, and bear quantities of pretty rosy tinted, *Tritonia*-like flowers, four of the petals of which are carmine spotted low down, and they expand so widely as to measure nearly 2 inches across. There is no marked colour variation, so far as I am aware, but I notice the salmon tints that underlie the rose are more intensified in a deep, rich soil, and in my experience one cannot cultivate the plant too well. Clumps 3 feet high and through are by no means uncommon, and there is a dainty poise in the inflorescences that many hybrid *Montbretias* lack.—G. B. M.

Colchicum Bornmulleri.—This is without doubt the finest and most beautiful of all the *Colchicums*. It has a large bulb, larger than a man's fist, and several flowering growths are produced from each; in fact, one may expect a dozen flowers from each bulb if in good condition. They are nearly a foot long, and have stout, angled, greenish tubes, and rosy lilac petals of considerable substance. The exquisite form of the flowers is seen best when they are raised to the eye-level on some rocky ledge, whilst specimen clumps growing in grass are none the less charming on a sunny day, the deep white pool in the centre of each flower is a very distinct and beautiful feature. Though still a rare plant it is of rapid increase. Huge seed-pods appear with the leaves in spring, and the seeds germinate on the slow but sure principle, whilst the bulbs generally split up into two every season. *C. speciosum album* is the next best *Colchicum*, its flowers are a pure white, and very beautiful. Its value, however, is still reckoned in guineas, so that it will be some time before one can have it in quantity for the one great use for which *Colchicums* are especially adapted—grass planting. *C. Bornmulleri* is much more reasonably priced. It is a plant with a great future in the embellishment of English gardens. A deep and heavy loam suits it best.—G. B. M.

Two hardy white Jasmines.—That there are two distinct forms of the hardy white *Jasmine* grown in gardens seems to be very generally overlooked, yet such is the case, and both are very freely distributed. Take first the white *Jasmine* itself, the *Jessamine* of old writers, which inhabits a considerable tract of country from Persia to Northern India, and is said to have been introduced as long ago as 1548. At all events, it has for generations been a popular plant for cottage walls, arbours, &c., the white sweet-scented blossoms, whose tint contrasts so markedly with the deep green of the prettily divided leaves, making it a universal favourite. The other form is of stronger growth, the individual flowers larger, and with a slight purplish tinge on the exterior, which is more pronounced in the bud state than afterwards. The young leaves and growing points of the shoots are

also tinged with red, which is wanting in the older form. The larger one is the variety affine of the "Dictionary of Gardening" and the "Kew Hand List." I have also met with it under the name of *Jasminum grandiflorum*, but the true species bearing this name is a native of Malaya, and is, therefore, tender. While many of the greenhouse and stove *Jasmines* bear white flowers, yellow is the colour most represented among the hardy ones, for of this hue we have *J. floridum*, from China; *J. fruticans*, Southern Europe; *J. humile* (syns. *J. revolutum* and *J. wallichianum*), Himalayas; *J. nudiflorum*, China and Japan; and *J. primulinum*, Yunnan.—T.

Laburnum cararnanicum.—This very interesting and little-known plant is one that is well worth growing on account of its late flowering. In general appearance it differs widely from the better-known spring-flowering species, and has at various times, by different botanists, been called *Podocytisus cararnanicus* and *Cytisus cararnanicus*; it is now, however, admitted to be a true *Laburnum*. It is very widely distributed, being found in Asia Minor, Albania, to Southern Greece and other places. At Kew several plants are to be seen, which were obtained from Mr. Transon five or six years ago. Its habit is that of a loose-growing *Cytisus* rather than a *Laburnum*. It grows but a few feet high, and is thinly clothed with small, trifoliate leaves, the centre one of which is much larger than the others. The flowers are produced during August and early September; they are deep yellow in colour, nearly half an inch long, and borne in large, loose, terminal panicles, the whole inflorescence being 9 inches to 12 inches in length. It grows under the same conditions as species of *Cytisus*, but takes longer to make a good sized plant than most other hardy Leguminosæ.—W. DALLIMORE.

NOTES ON HARDY PLANTS

HARDY YUCCAS IN GROUPS.

WHETHER space can be afforded, and suitable situations can be found for them, the hardy *Yuccas* should be grown. Few hardy subjects are so distinct in leafage and manner of growth as these; but to see them to the best advantage they should be arranged in bold groups, and in the immediate vicinity of such trees and shrubs as are best fitted to form a harmonious contrast to them. Perhaps the best situation for them is a sloping bank or piece of land, fully exposed to the midday sun, and backed up by evergreens of some kind. Thus placed, and allowed ample space for development, they will gain in beauty from year to year, and when in bloom will form a striking feature in the pleasure ground. The handsome spikes of large cream-coloured flowers are extremely effective, especially when thrown into bold relief by the mass of verdure behind them. *Yuccas* like a well-drained soil, and thrive well where the subsoil is pure chalk. They delight in full exposure to the sun, and enjoy the shelter from rough winds which a stronger vegetation is capable of affording them; hence the advisability of planting them in tolerably close proximity to trees or shrubs of some kind which may screen them, not only from rough westerly gales when in bloom, but will also insure them against the withering influence of easterly or northerly wintry winds. The *Yucca* is a hardy plant, but the foliage of several of the most ornamental species, such as *filamentosa*, is apt to get either torn or discoloured when the plants are growing in free exposure, and when the leaves become much injured the decorative value of these fine hardy subjects is much diminished. A little discrimination in the choice of situation will, however, be all that is necessary to ensure their perfect safety in this respect, and there are few gardens where suitable accommodation could not be found for them.

In grouping *Yuccas* a wonderfully fine as well as a more free and natural effect is obtained where a proportion of the specimens employed have attained sufficiently large dimensions to raise the head of

foliage some 3 feet to 6 feet above the soil; these tall plants should not, however, be placed in a regular manner in a back line, but one here and there should be allowed to advance somewhat into the foreground, with some of the smaller specimens nestling at their feet. The effect of a group thus arranged charms by its irregularity and quaint beauty, and forms a picturesque and distinct feature in the garden landscape. I have often thought that we do not sufficiently value these noble hardy plants, for one seldom sees a bold, free use made of them, the owners of gardens generally being content with employing them on the dot system, which cannot be said to convey an adequate idea of their high qualities. It should be the aim of all who may have a large extent of pleasure ground to embellish it with plants of an enduring character, to create as much diversity as possible; this can be well effected by grouping families of plants having distinctive features in situations most favourable to them, avoiding as far as possible all semblance of regularity and formal outline. The Yuccas, offering as they do a complete contrast to all other forms of hardy vegetable life, may be made good use of in carrying out this idea, for by their means alone a distinct and interesting piece of garden scenery may be created. As before stated, the hardy Yuccas are children of the sun, and they do not as a rule flower freely unless they get a good baking in the summer; they need apparently a large amount of maturation to perfect their growth and prepare it for the production of bloom. With respect to soil, they can scarcely be termed fastidious, but it must be well drained. They appear to be perfectly at home where the subsoil is pure chalk, attaining a rude vigour, and flowering freely when thus situated.

J.

THE PASQUE FLOWER (ANEMONE PULSATILLA).

ABOUT ten years ago the late Mr. G. Wilson gave me a nice plant of this Anemone. It had one expanded flower and many buds in various stages of development. I planted it in a raised bed in light loam, and there it is still, a fine healthy specimen, which annually delights with a profusion of fine purple blooms. From this plant I have raised many seedlings, but until last year I had no success in getting them into the flowering stage. I kept them in the seed-pans the first season, and planted them out the following spring just before they began to grow. I put them in the same soil that I found so suitable for the parent plant, but only about half-a-dozen out of fifty grew away. The next lot I put out in early autumn, with equally unsatisfactory result. Evidently something was wrong, and it then occurred to me that this Anemone must belong to that class of plant which, like *Stipa pennata* and *Polygonum vaccinifolium*, can only be safely removed after growth has fairly commenced and just as new roots are pushing out. Last spring I set out about 100 seedlings just as they were making their second leaf, and not more than five of the lot failed. The Easter Anemone or Pasque Flower is exceedingly attractive when in bloom, and if one can only get a colony of a score of plants to take on perennial vigour the effect is very fine. There is a white variety of this Anemone named White Swan, which is apparently somewhat scarce at present; but it is curious that, in a general way, there is so little tendency to variation.

J. CORNHILL.

MECONOPSIS INTEGRIFOLIA.

MECONOPSIS INTEGRIFOLIA is now in flower in Messrs. Bee's nursery at Neston, Cheshire. It turns out rather a surprise. From the size of the flowers it has been customary to think of the plant as the giant of the family. But as grown here it has more the appearance of an alpine. The soft hairy leaves are lanceolate and entire, and have not so far exceeded a maximum length of 12 inches. The flowers, each borne on a stout peduncle, 12 inches to 14 inches long, measure when fully expanded 4 inches across, and are of a delicate soft yellow colour. They rise in continuous succession

from the thick tuft of leaves. It is an additional attraction to this fine plant that, in contradistinction to most other Eastern members of the genus, it is expected to prove a perennial. Its present habit and appearance quite confirm this belief.

Messrs. Bee only ventured to trust one plant out of doors last winter, and, curiously enough, it has flowered, while the others, carefully tended in pots under glass, have failed to do so. The plant is growing in a very shady position, under a north hedge in the neighbourhood of a frequent but intermittent supply of water.

Meconopsis integrifolia is not a Himalayan plant. Its habitat is in the high mountainous regions of China and Tibet. The seeds from which the plants were raised were gathered by the Koslov Expedition, sent by the Russian Government to Central Asia.

Other rare *Meconopsis* in Messrs. Bee's nursery are the tall-flowered iridescent *M. grandis*, the variable *M. racemosa*, with flowers shading from deep purple to palest lilac, and seedlings of the rare *M. bella*. This last species is considered by the few who have seen it on its native rocks as perhaps the most beautiful of all Himalayan plants. Unfortunately, it has proved impossible so far to raise it past the seedling stage. It grows on wet rocks, constantly surrounded by cloud and mist, but never getting direct rain. These conditions it seems impossible to reproduce. W. COURTS.

AN EXCELLENT WHITE LATE TULIP.

TULIPS are among the most useful bulbs in the garden, especially those of decided colouring. The double kinds last longest, and this is of considerable importance when they are planted in the open garden. It is astonishing how long some kinds remain in bloom, *La Candeur* especially. We grow this both under glass and in the open, and no double late white Tulip gives so much satisfaction. Last spring it was splendid in groups alone and mixed thinly amongst *Myosotis*. Some of the blooms lasted nearly a month. One feature worthy of note in this variety is that the sun does not spoil it, as it does many white flowers. Where a white Tulip is wanted for decoration this is most useful. Added to this it is a good grower, and the bulbs can be had cheaply. J. CROOK.

ROMNEYA COULTERI AT CULZEAN CASTLE.

FAVOURER as it is by a mild climate, Culzean Castle, the Ayrshire seat of the Marquis of Ailsa, presents many opportunities for the cultivation of difficult or tender plants. For some time experiments have been going on with such plants, and the successes have been notable. *Cordylines*, *Bamboos*, *Eucalypti*, *Palms*, and other things of the kind have been attempted with general success, although the winds prevent the *Palms* from attaining their full beauty. Among the finest plants this year have been the *Romneyas*, of which there are a good number of plants of *R. Coulteri* in the open. These have done remarkably well, and some were upwards of 9 feet high and flowered very satisfactorily. Mr. David Murray, the Marquis of Ailsa's experienced gardener, is to be congratulated on the success of the *Romneyas* here. S.

PEONIES IN GRASS.

ONE of the boldest things we know of in wild gardening, and certainly the most brilliant, is the putting of a group of scarlet Peonies in meadow grass. In the future of our gardens there is a good deal to be done by the tasteful cultivator in considering well the positions suited for some kinds of plants. It is easy to so arrange plants, for example, that are very handsome in spring and early summer, but do not continue in perfection into early autumn, so that their effect when out of flower, or even their disappearance altogether, will not mar any "composition." The point is a very important one and well worth attending to. Peonies are among the plants that deserve this kind of attention. If they are grown for their flowers only, or their buds, or for the purpose of increasing them, they may be placed in nursery lines in some rich part of the

kitchen garden. In such a position one would soon have enough to spare for putting a bold group in some place.

THE PURPLE ORPINE

(SEDUM PURPURASCENS.)

NONE of the Stonecrops, or Livelongs as they are sometimes called, are so variable as the British species *S. Telephium*. No fewer than twenty forms have received names either as sub-species or varieties, but of these our native *S. purpurascens* is as showy as any of them, and the most desirable for cultivating as a border flower. It grows from 1 foot to 2 feet high, and has stout erect stems furnished with roundish fleshy leaves, and terminated by dense broad clusters of blooms usually of a bright rosy-purple hue, but sometimes white. It is not an uncommon plant, and may be found generally distributed about the country, usually growing in hedgerows and thickets, where late in summer and in autumn it produces its showy blossoms. In the garden this Stonecrop, and indeed all the other varieties and allied species of about the same size, are particularly useful for planting in places which would be too dry for other plants, such as on rough rockwork and dry borders; of course they prefer, however, to be treated as liberally as other plants, and well repay any attention by growing and flowering more vigorously. When cut, the flowers last a long time in perfection; the stems are so tenacious of life after they have been severed from the root that they are often called Everlasting Livelongs. W.

ROSES—PAST, PRESENT, AND FUTURE.

BY THE LATE DEAN HOLE.

(Continued from page 176.)

OF course, we shall secure under glass a sure and ample display, but when we have one of those genial Mays of which we read much and see little, we shall find more richness of colour and a larger development of form in the Roses which grow upon the wall. Other distinguished climbers, although not members of the *Rosa alpina* family, have risen to pre-eminence since the arrival of *Maréchal Niel*, and claim a place in every large rosarium; *Rêve d'Or*, 1869; *Belle Lyonnaise*, 1869; *Mme. Bérard*, 1870; *Bouquet d'Or*, 1871; *Cheshunt Hybrid*, 1873; *Reine Marie Henriette*, 1878; *William Allan Richardson*, 1878; *Mme. Alfred Carrière*, 1879; *Reine Olga de Wurtemberg*, 1881; *L'Idéale*, 1887; *Turner's Crimson Rambler*, 1893; *Alister Stella Gray*, 1894; *Paul's Carmine Pillar*, 1895.

All these are excellent. *Cheshunt Hybrid* loses too soon the beauty of its complexion, but we may not be hypercritical with the few crimson Roses which climb, and *L'Idéale* varies in her behaviour, like the damsel who

"When she was good, she was very, very good,
But when she was bad, she was 'orrid.'"

But the rest, like *Phyllis*, "never fail to please." They are excellent for walls, pergolas, trellises, and pillars, and also, with the climbers previously named, for planting in shrubberies. From the room in which I am writing I can see a dozen *Gloire de Dijon* Roses blooming, some 10 feet from the ground, in a clump of evergreen and flowering shrubs. They seem to salute me with a friendly and familiar nod, smiling their sympathy with one who appreciates, admires, and loves them. The bright colours of the flowers and the dark foliage of the shrubs make a charming contrast—the most successful formation which I have seen of a "Mutual Improvement Society."

The combinations are infinite, and I may cite, as a striking example, a Crimson Rambler making love to a Silver Maple, *Acer Negundo variegatum*, the more remarkable, because the Rambler, in accordance with his title, prefers to roam abroad in perfect freedom, as a bachelor unattached. The happy vagabond is terribly distressed in gaol.

The American Rose *Wichuraiana* and its hybrids are of recent introduction. Lord Penzance's Sweet Briars must not be omitted from the foreground of those borders in which we blend our Roses and shrubs.

Success depends, of course, upon obedience to the immutable law of labour, faith which worketh by love. Sentiment in easy chairs, and books, and pictures, and bouquets do not produce beautiful Roses. They require manure and a hoe.

In further fulfilment of my promise to make a selection of the fittest from the different classes of the Rose, I pass from the climbing varieties to those of lowlier stature which are most reliable for beauty and endurance, not only for their form, but for their staying powers. Among these the section known as Hybrid Perpetual has not only maintained a long and universal pre-eminence, but has monopolised almost exclusively until a recent date the admirations and attentions of the hybridiser, the exhibitor, and the connoisseur.

It may be noticed *en passant* that the boundaries which divide these two sections are by no means so broad as they are generally supposed to be. A large number of Hybrid Perpetual and other Roses, especially the Teas, will develop a surprising vigour when planted against a wall or trained upon poles in a congenial site and soil. Intimations of this power may be found in our budding grounds (I measured a branch of my namesake, Reynolds Hole, 9 feet in length), and observant rosarians, acting upon these suggestions, have given us our Climbing *Devoniensis*, Captain Christy, Jules Margottin, Niphetos, Perle des Jardins, and Victor Verdier. The multiplication and improvement of these Hybrid Perpetuals is marvellous. I have before me the catalogue of one of our most honoured, enterprising, and successful Rose merchants, in which he enumerates 260 varieties of the Hybrid Perpetual Rose. Not one of these was in existence fifty years ago! General Jacqueminot and Jules Margottin arrived in 1833, Senateur Vaisse in 1859; all the rest have come to us in a lovely procession during the last forty years.

I have grown, and have shown successfully, the best of these Roses which were in our gardens before I ceased to exhibit, and since that time have added to my collection the new varieties of superior merit, so that I could readily present to my readers a long and reliable list; but it is my present object to promote the appreciation of the queen of flowers, and to extend, through the usual process of annexation, Her Majesty's Empire, by helping those who

are inclined to begin, or have only just begun, the culture of the Rose, and therefore I make such a selection as will most surely recompense a small outlay of time and money with a great encouragement and a beautiful reward. I commend, accordingly, La France (also included with the Hybrid Teas), Mrs. John Laing, Ulrich Brunner, Prince Camille de Rohan, Captain Christy, Duke of Edinburgh, Grace Darling, Her Majesty, Charles Lefebvre, Baroness Rothschild, Prince Arthur, and Merveille de Lyon.

For the amateur desiring a longer list I propose: Alfred K. Williams, Dr. Andry, Etienne Levet, Fisher Holmes, Francois Michelon, General Jacqueminot, Gustave Piganeau, Louis van Houtte, Mme. Gabriel Luizet, Mme. Eugene Verdier, Margaret Dickson, Marie Baumann, Paul Neron, Reynolds Hole, Senateur Vaisse, Sultan of Zanzibar, and Victor Verdier. There are other candidates for admission. The Hybrid Perpetual Roses, which for more than half a century have been pre-eminent as Court favourites, the *elite* of the *beau monde*, associating almost exclusively with "our set," are now confronted by rivals, who not only claim to meet them side by side as equals, on great festivals, in high places, even in the Palace (Sydenham), but are preferred by many rosarians for their more delicate and diverse tints, their exquisite form, their glossy foliage, and their longer continuity of bloom. With a slow but sure success they asserted their claims to our admiration. I remember a time when of the nurserymen Mr. Benjamin Cant, and of the amateurs Mr. Hedge, both from Colchester, were almost the only exhibitors of Tea Roses, and the *Souvenir d'Elise* of the former, and the *Mme. Bravy* of the latter, were envied by the brethren like Joseph's coloured coat. Adam, *Mme. Willermoz*, *Souvenir d'un Ami*, and *Devoniensis* were more commonly shown, and none who saw will ever forget three blooms of

the latter Rose, which were sent by John Keynes from Salisbury to the Birmingham show. As one of the judges, I was quietly making notes and observations with my learned brothers, when we stopped suddenly, simultaneously, like soldiers at the "halt," and with eyes and mouths wide open we gazed, first at the flowers, then at each other, like children astonished at a pantomime, and wanting to know how it's done.

(To be continued.)

NOTABLE GARDENS.

LANGLEY PARK, BUCKS.

AMONG the many country homes in the delightful county of Bucks, Langley Park, the residence of Sir Robert Harvey, Bart., is not the least interesting; it possesses several features that are well worthy of notice by those interested in gardens. The house is situated amid surroundings that only the pen of Gray did justice to. The park that encircles it is finely timbered with Oak and Elm that our forefathers of some 300 years ago planted so wisely and so well in various counties, and perhaps especially so near the Royal domain in the bordering counties of Berks and Bucks. The pleasure grounds around the house and the fruit and vegetable garden abound in conifers; the collection is an extensive one, and contains several unusually fine specimens, *e.g.*, *Abies nobilis*, *A. grandis*, *Wellingtonia gigantea*, *Pseudotsuga Douglasii*, and others. During recent years the grounds have been greatly improved; what, two years ago, was a huge mass of Laurel and *Rhododendron* is now a picturesque grassy glade bordered on the one side by a shrubbery filled with good things, while on the other the lawn

THREE YEAR OLD HONEYSUCKLES AT LANGLEY PARK, BUCKS.

stretches away beneath stately Wellingtonias towards a wilder shrubbery, and a small water garden with Nymphaea-covered surface and Iris-clothed margin gives a touch of freshness and relief. Glancing down the glade one gets a view of the park, whose giant trees, solitary, in twos and threes or in clumps, suggest, as it were, the heavily wooded hills and vales that lie beyond.

The most remarkable tree at Langley Park is the Lebanon Cedar, probably an unique specimen in this country. It is situated close to the house, and its huge dark limbs, whose branchlets sweep the ground for yards around, produce an effect at once gloomy and grand; this, however, is somewhat relieved by the beds and borders bright with summer flowers and the various tints of green and grey of other trees near by, insignificant though these seem beside the giant Lebanon. Mr. Gillies, the head gardener at Langley Park, has kindly sent the following measurements of this tree: Circumference of trunk, 24 feet: diameter of spread of branches, 48 yards: circumference of spread of branches, 150 yards: height, 80 feet to 90 feet. The average growth made by the branches this year is 9 inches. Another most interesting feature of the garden is a Honeysuckle-covered wall, which, together with the Cedar, we are able to illustrate. This wall is some 25 feet high, and, although the plants were only put in two years ago, they have now practically reached the top of the wall, as may be seen. Mr. Gillies has given them fairly liberal treatment, but they have not had much attention beyond never being allowed to want water. Such a growth of Honeysuckle in two seasons is remarkable. There are three or four plants.

Even without the Lebanon Cedar and the Honeysuckle, however, Langley Park would still be well worth a visit in order to see the Japanese garden. This was made and planted in the winter of 1901 upon the site of a stable

yard, and a glance at our illustration of it in its present form will show what a transformation has been effected. A stream, placid and rippleless it is true, moves slowly and circuitously between banks clothed with the mammoth-leaved Gunnera, Berberises, the grey-green graceful leaves and stately plumes of the Pampas Grass. A Crimson Rambler partly hides the woodwork of the rustic bridge that spans the water, its rich scarlet blossoms drooping to the water's edge, and meeting their own bright shadow reflected there. Clumps of Bamboos, Japanese Irises, Lilies, Funkias, and other plants in pleasing association suggest Japan and her own peculiar taste in gardens. Bamboos thrive amazingly at Langley Park: there are some splendid clumps of Arundinarias and Bambusas. As a matter of passing interest it might also be mentioned that Mr. Gillies grows Mangoes under glass most successfully: he has produced fruits that Sir Robert Harvey declared to be as good as any he had tasted in India.

H. H. T.

THE WARREN, HAYES, KENT.

THE gardens at The Warren, Hayes Common, have been so long associated with all that concerns the welfare of the Carnation that the garden-loving public have almost come to regard its productions as indissolubly identified with the progress of this delightful flower. To Mr. Martin R. Smith lovers of gardening will always be indebted, for he has largely added to our collections of this plant. Few persons are aware of the extent to which the cultivation of these beautiful flowers is carried. We first saw the plants that had flowered in the open border. They were disposed in a series of serpentine beds, with a number of small square beds cut out of the lawn alongside, the latter being used for plants of one variety, and certainly a most effective method of planting too. The layering of these plants was completed and, all drought notwithstanding, looked full of promise. To show the immense amount of work entailed in the cultivation of the Carnation we may mention that

10,000 are layered outdoors, 10,000 in pots under glass, and no less than 15,000 seedlings are also raised in one season. It is difficult to appreciate what these figures actually mean, but to see the work in actual progress is very convincing indeed. Four men had been layering for some weeks on the occasion of our visit in late August, and their labours would not be finished until the end of September.

The light and roomy glass structures in which the plants are flowered are ideal for the purpose. There are several houses specially set apart for the purpose of seed-saving. An immense number of seed-pods were developing, and others were maturing, and spread out on a mat in a sunny position we saw what seemed to be some hundreds of specially-designed paper seed-pockets, each bearing the nature and history of its contents. The names of the varieties crossed were duly noted on each packet, and these, if used in raising seedlings at this establishment, are duly entered in a register that the parentage and other useful facts may be traced as occasion arises. It may be wondered what becomes of many of the plants, and that the system even in this matter may be appreciated, one instance will, perhaps, suffice. In the houses where the plants are ripening their crop of seed, we noticed that some of the labels had a bar of blue paint across them and others a red bar. Upon enquiry we were informed that these marks denoted that in one case the plants were to be perpetuated, and in the other case they were to be discarded. In this way a high standard is maintained.

From the Carnations we passed on to the Chrysanthemums. None of the plants appeared to be in pots more than 9 inches in diameter, and quite a large number were being grown on single stems in 6-inch pots. Almost without exception the plants gave evidence of skilful culture; the wood was well ripened, and the buds in many instances were developed in excellent time. The plants were arranged along the edges of the paths of the kitchen garden, and were better sheltered from the wind than those grown in gardens more exposed. Of the more recent introductions we noticed good plants of Lady Cranston (sport from Mrs. Barklay), Dorothy Pywell, Mildred Ware, Bessie Godfrey, F. S. Vallis, General Hutton, Mrs. Dunn, Sensation, Maud du Clos, Masterpiece, Mrs. Greenfield, Lord Hopetoun, Godfrey's King, and Guy Hamilton. The foregoing were some of the better Japanese. Incurved sorts were coming very well, and bid fair to give a good account of themselves later. Mr. Blick is a well-known grower and exhibitor of the Autumn Queen. The Grapes looked well, some of the Vines carrying heavy crops of large bunches of well-coloured berries. The somewhat new variety Appley Towers was very fine and large, and bearing handsome bunches. Lady Hutt is another somewhat new sort that is highly prized here. The bunches hang till March, and they are of a grand flavour.

The orchard house, with its trees in pots, is always worth a journey to see. Peaches, Nectarines, Plums, Pears, &c., were to be seen, and others were outside for succession in a specially erected wire enclosure. The herbaceous border, like many others this season, was suffering severely for the want of rain. Most of the plants had shrivelled long before the blossoms had matured, and such a state of affairs is a matter in which we can all sympathise. Plants of late summer-flowering perennials, such as the herbaceous Phloxes, should have

THE FAMOUS CEDAR OF LEBANON AT LANGLEY PARK. (Height, 80 feet to 90 feet; spread of branches, 150 yards round; girth, 24 feet.)

been at their best, but they were represented by shrivelled and burnt specimens. The same remarks apply to many other plants. A rock garden is now in course of formation. This is situated in a cool and sheltered position. The plants already planted are thriving well, and the rock garden bids fair to make a welcome addition to the other features of this interesting garden.

D. B. C.

BOLD WATERSIDE PLANTS.

(Continued from page 177.)

BUTTERBUR (*Tussilago Petasites*).—This is a noble plant when in its largest state, and a little colony of it looks pleasing by the banks of a stream, where it delights to spread.

The Burdocks, too (*Arctium*), though they naturally affect poor, dry soils, attain enormous dimensions by the side of water, but they must not be planted so near that their roots are submerged.

SWEET FLAG (*Acorus Calamus*).—This is a Reed-like plant, growing some 3 feet or more in height. It is a very vigorous plant, and soon spreads itself over a wide area, and will overrun plants of weaker growth if not checked. It is, however, a handsome plant, and the highly aromatic leaves make it the more desirable. It should be planted at the base of a projection, or, better still, around an islet, so that it may be kept within bounds. The Bur Reed (*Sparganium*) is somewhat similar, but more tufted than the Sweet Flag, and not nearly such a rapid grower.

THE GREAT BULRUSHES OR CAT'S-TAILS (*Typha latifolia*), which in autumn are furnished with black, club-like flower-spikes, though abundant in many parts of the country, should always be planted where not indigenous, as they are so distinct in aspect from most water plants. *T. stenophylla* and *T. minima* are alike graceful plants, growing in tall, dense tufts.

PONTERIAS, of which there are three species, are about 3 feet high. They have arrow-shaped leaves and blue flowers of various tints, produced on stout stalks well above the foliage. The three kinds require to be planted in 1 foot or so of water, and are therefore well adapted for planting a little way from the margin. Another noble plant which, unfortunately, is not quite hardy is *Thalia dealbata*, a Maranta-like plant from South Carolina, growing some 6 feet in height, with large, handsome leaves of a glaucous green hue.

FLOWERING RUSH (*Butomus umbellatus*), one of our native plants, should adorn the margins of every piece of ornamental water, as it is not only an elegant plant as regards foliage, but its blossoms, which are produced in large umbels, are rosy tinted and beautiful.

THE WATER PLANTAIN (*Alisma Plantago*) is a bold plant, which often attains 3 feet in height. It grows in watery ditches and edges of streams. The leaves are broad, similar to those of the Great Spearwort.

CALADIUM VIRGINICUM is a noble Aroidaceous plant, having large, broad leaves, arrow-shaped, and of a deep green. It is excellent for planting in shallow streams or pools, in about 6 inches of water. It rises 2 feet or 3 feet in height in a manner similar to the Callas or Richardias, which should on no account be omitted. Other highly ornamental North American water plants are the

GIANT HORSETAIL (*Equisetum Telmateia*).—This is an extremely fine plant when fully grown, and one which attains several feet in height in moist, shady places, producing graceful plumes of pendulous, thread-like branches in drooping whorls of a cheerful green colour. It is by far the finest of all the Horsetails, but seldom seen in full growth. The finest group we ever saw was in the garden at Bitton, where Mr. Ellacombe had it growing near a wall, and there it had a very handsome appearance.

There are many other plants, which though not strictly aquatic, flourish well near water, and have a fine effect, as, for example, the Flame-flowers. Other plants may be similarly treated, such as the

IN THE JAPANESE GARDEN AT LANGLEY PARK.

Giant Knotweed (*Polygonum cuspidatum* and *sachalinense*), *Astilbe rivularis*, *Senecio japonicus*, North American Lilies, several of the larger Spiraea, Trollius, the Royal Fern (*Osmunda regalis*), *Lysimachias*, and many others.

A LAVENDER GARDEN.

TOWARDS the close of July the space within the fences surrounding the quaint old homestead might well be termed a Lavender garden, although many old-fashioned flowers beloved of our grandmothers and dowered with the priceless gift of fragrance, such as Bee-balm or Bergamot, Woodruff (with its scent of new-mown Hay), Allspice, Rosemary, Clove Carnations, Balm of Gilead, double Rockets, Southernwood, and Cabbage Roses find places in the beds, but, even before the wicket-gate is reached, the air is filled with the perfume of thousands of flowering spikes of Lavender. On one side a Lavender hedge, separated from the adjoining meadow by a deep ditch and bordered by a narrow path, runs the whole length of the garden. On either hand of the porch stand two huge bushes of Lavender, and Lavender again fills the whole of a plot some yards in length and breadth just within the hedge of Monthly Roses that faces the winding village road. From above the lattice windows, into which Jasmine and Honeysuckle peer, the house-martins pass and repass to their nests beneath the wide thatched eaves, fleeting visions of black and white. In the air there is a murmurous hum, the wing-song of the busy brown hive-bees and of their burly yellow-banded cousins the humble-bees as they rifle indiscriminately the blossoms of Lavender, Rose, or Carnation, while, like winged flowers, butterflies, white, yellow, or blue, flutter nonchalantly hither and thither.

There is no jarring note to mar the ideal peace of the Lavender garden. The eye is charmed with the white summer cloudlets drifting gently across the deep blue sky, and with bird and blossom: the ear is lulled with the soft music of the bees, and for the sense that

is more obscure than those of sight and hearing there is the delight of "fragrance," which, "as has been well said, is the song of the flowers." Lavender is no new aspirant to popular favour, but enjoys the dignity of old-world associations, for from the time it was first cultivated in this country—more than 300 years ago—its perfume has been valued by the housewife, and the snowy folds in the Cedar linen-chests of our ancestresses were scented with the odorous sprigs that lay enscathed within them.

The first growers of the Lavender in this country were the Huguenots, who, when they fled from France, continued its culture in England. The valley of the Wandle was the favoured spot with these originators of the industry in our land, and the names of Lavender Hill and Lavender Sweep still remain as evidence of an industry that the increase of population has now driven further afield. At the present time Lavender is chiefly grown in the Surrey district of Mitcham and in the neighbourhood of Hitchin, in Hertfordshire, though not many years ago the celebrated perfumers, Messrs. Piesse and Lubin, cultivated a considerable acreage of the fragrant plant in close proximity to the Crystal Palace. Although the Lavender is a native of Southern Europe, Northern Africa, the Canary Isles, and Persia, and might, therefore, be considered too tender to withstand the rigours of our more northern climate, it sustains but little damage from frost except during very severe winters. The flowers of the Lavender are either used for distillation or are cut and marketed in bunches, in which form they are to be seen in quantity in the streets of the Metropolis and large provincial towns. Distillation still yields fair profits, though the price of the best English Lavender oil has decreased greatly of late years. Formerly Mitcham oil sold at £10 per pound, but lately has fallen to about a quarter of that price. This decline, which is mainly due to the flooding of the market with cheap and inferior foreign oil, distilled from the blossoms of the wild Lavender, has caused growers in some instances to abandon the culture of the plant, while considerable loss has occurred owing to plantations being devastated by a form of mildew.

Lavender is not exacting in the matter of soil, but extremes of richness and poverty are to be avoided, the former causing too vigorous and sappy growth, which is apt to be injured by the frost, while the latter is incapable of supplying the plants with sufficient nourishment to enable them to perfect a full crop of flowers. Fibrous loam overlying a subsoil of chalk is held to be best adapted to remunerative Lavender culture, while a slope with a southern exposure, and sheltered on the north and east, is the ideal site. Plants are propagated by taking slips from the old bushes in October. These are set in the ground in rows a foot apart, and thinned out and replanted the following autumn. In the permanent plantation the bushes stand 3 feet apart. The form

Almost all large plantations possess stilleries, which are generally large enough to permit of carts being driven in to discharge their loads of flowers under cover. Many stills are of sufficient size to contain a ton weight of Lavender. When the still is to be filled the head is lifted and the flowers shaken in from the mats and trodden down until tightly packed, when the head is secured and the furnaces started. As soon as the liquid expressed from the flowers reaches the boiling-point it runs through a coil of tubing immersed in cold water, which causes condensation, the oil separating from the water and being collected in a receptacle at the base

Raspberry Colwill's Red Diamond is the result of a selection from seedlings of the old Red Antwerp, but far superior in every respect to this variety. It is probably destined to extend the Raspberry season considerably, for Mr. Colwill writes on the 8th inst. that he is picking quantities daily, and at the remunerative price of 1s. per pound. Mr. Colwill continues: "With regard to size few varieties are equal to, and none surpasses it. It commences to fruit as the well-known sort Super-

A NEW RASPBERRY—COLWILL'S RED DIAMOND.

(Natural size. Shown before the Royal Horticultural Society last week by Mr. Colwill, Sidmouth and given an award of merit.)

known as Mitcham Lavender is most generally grown, as this variety produces the essential oil in the greatest quantity. The blossom harvest usually takes place in August. Large bushes will bear 200 or more flower-spikes, which are cut with a Lavender-hook, an implement slightly narrower and more bent than an ordinary reaping-hook. With this it is said that a practised hand will clear a bush with one sweep. When the flowers are cut they are laid on the top of the plant, whence, if destined for the market, they are collected and bunched by women. If intended for distillation the spikes are not cut until the flowers at the base have faded, this being the time that they contain the greatest supply of oil. The bloom-spikes intended for distillation, when reaped, are left lying on the bushes for two days or so, being turned once to hasten the drying, after which they are thinly spread out in the sun on Archangel mats and the drying completed. When once thoroughly dry they may be, if necessary, stored for months previous to distillation, without any danger of deterioration from mildew.

of the still, from which it is run off into dark glass bottles, holding from 5lb. to 7lb. each. The Lavender harvest is quite as dependent upon the weather as are the hay and corn harvests, and a given acreage will often, on a dull and damp summer, fail to produce half the amount of oil that it would have furnished in a favourable season. The profits of the industry are, therefore, naturally fluctuating, but anything above 25lb. of oil to the acre may be considered a fairly satisfactory yield.

S. W. FITZHERBERT.

NEW AND RARE PLANTS.

RASPBERRY COLWILL'S RED DIAMOND.

A VALUABLE late variety this new Raspberry appears to be. It was shown before the Royal Horticultural Society on the 6th inst. in excellent condition, and then obtained an award of merit. The fruits are above medium size, dark red in colour, and of sweet and pleasant flavour.

relative is almost over, and will prove a good successor to it. As to habit of growth, this leaves nothing to be desired." From the fruiting branches shown last week the new Raspberry is evidently a free-bearing variety.

CAMPANULA HYBRIDA FERGUSONI.

A good deal of interest attaches to this new hybrid Campanula, which obtained an award of merit from the Royal Horticultural Society last week when shown by Mr. F. W. Smith, gardener to G. Ferguson, Esq., The Hollies, Weybridge. The parents are *C. pyramidalis* alba and *C. carpatica*. The result of the cross is virtually a dwarf and slender *C. pyramidalis*, yet without the close setting of the flowers as in that species. It has another excellent feature, too, in that numerous stems are produced from the same rootstock. The large, cup-shaped flowers are pale blue, and are freely produced.

TREES AND SHRUBS.

THE SCOTCH FIR.

(PINUS SYLVESTRIS.)

INDIGENOUS to North Britain, where, at one time, hundreds of square miles of hill and dale north of the Grampians were covered with this tree, and abundantly planted throughout the kingdom, the Scotch Fir is too well known to need description. It may still be seen in its original beauty in the forests of Aberdeenshire, Inverness, and Perth, clothing the mountain side and glen, and yielding excellent timber of large dimensions, little, if at all inferior, to English Oak for dry building purposes. In this respect, however, it is, of course, inferior to the yellow Deal of commerce, but highlanders assure us that the finest trees south of the Tweed do not produce timber equal to their own, and this inferiority in grain and durability is ascribed by Messrs. Veitch, in their excellent work, "The Manual of the Coniferae," to climatic causes, the long and severe winters of the north, succeeded by short and hot summers, giving the trees periods of rest and great activity of growth which they do not get in the more equable climate of Great Britain. London in his remarks upon the economic value of the timber says:

"The facility with which it is worked occasions its employment in joinery and house carpentry almost to the exclusion of every other kind of timber wherever it can be procured. It is at once straight, light, and stiff, and consequently peculiarly

fitted for girders, joists, and rafters, which may be made of smaller dimensions of this timber than any other. In point of durability, if it is kept dry, it equals the Oak, more especially if it has been of slow growth and is resinous. The Larch, its greatest rival, of late years has been most extensively planted, and certainly for use in a comparatively young state it is preferred in England; but then it is questionable if the soil as well as the milder climate of the south has not something to do with the quality of English-grown Scotch Fir, as all writers assert that the granitic formations so extensive in Scotland, independently of greater age, contain the elements most congenial to the Scotch Pine."

Ready and willing to yield the palm to the north, not only for immense clean trees, but also for economic quality, as lovers of picturesque trees and great planters of conifers generally we may point with pride to numbers of most beautiful specimens, many of them of great age, now beautifying our parks and giving the artist's finishing touch to the best arboreal scenery throughout England. There are many fine specimens near London, as observant travellers in the home and southern counties can testify. Some very fine clumps, a furlong apart on either side the long straight road leading from Heckfield to Strathfieldsaye, reflect very great credit on the taste of the planter, Lord Rivers, I believe. These are comparatively young trees, but having got into the splendid loam which underlies the Heath-clad sandy peat, they will be the admiration of all passers when another century has passed away. I wish I could say a good word for the modern

planter who has blocked these fine groups by covering the whole of this heath with young trees, now growing like Willows. Had the Farnborough vandal entered this out-of-taste copse he might have done the district good service.

Several varieties of the Scotch Pine are grown, but that called *Pinus horizontalis* is considered the most valuable timber tree. It is distinguished by its rapid and robust growth, by the horizontal or drooping direction of its branches, by its broad glaucous foliage, and by its producing cones but sparingly. This is supposed to be the true and original Highland Pine, and as such has been distributed all over temperate Europe. Soil, however, for there is no denying the fact that this tree enjoys a good root run, situation, and altitude, make a wonderful difference in the habit, contour, and colour of all conifers; so much so, that unless all the varieties could be seen growing together, I should say here we have a distinction without a difference.

When planted in large masses or broad belts, the Scotch Pine, owing to its quick growth and hardy constitution, is a useful tree for forming screens and as a nurse for tender conifers, which often grow freely enough when thoroughly established on our bleak hill-sides. As a single specimen on the lawn, like its rival the Larch, it is not despised, but to know it in full beauty it must be seen with its clean red stem, 30 feet to 50 feet in height, capped with glaucous grey branches, rising out of, or backed by, dense deciduous foliage. These clean-bolled stems, as a matter of course, are produced by close planting, drawing up, and self or natural pruning. W.

AN AVENUE OF FIRS.

ORCHIDS.

LELIO-CATTLEYA ELEGANS.

FOR the most representative collection of this beautiful natural hybrid one must turn to that owned by R. H. Measures, Esq., The Woodlands, Streatham. Here may be found the most valuable varieties known. The season of growth and flowering of *L.-C. elegans* and its varieties is most varied, and in a large collection like the one under notice some form or other may be had in bloom at almost any time of the year, but the best season is during the months of July and August. To discuss all the noteworthy specimens in this superb collection would take up more space than we have at command; but mention should be made of *L.-C. e. var. R. H. Measures*, one of the choicest varieties, having sepals of a somewhat peculiar but most pleasing colour, a soft cream yellow tinged with green and lightly touched with rose. The petals are flushed with rose and pencilled with darker lines, lip a bright purple dashed with fire-red; a broad stripe of the same colour passes from the front area to the foot of the column; with that exception the remainder of the inner surface is a soft white, on the outer side soft rose tipped with red-purple. The two varieties *L.-C. e. Sylvia* and *L.-C. e. Rupert superba*, which have flowers of enormous size, are probably the two finest forms of *elegans* known; but for varieties alike noteworthy for their remarkable colouring and form mention should be made of *L.-C. e. Woodlandense* and *L.-C. e. F. Sander*. The former has sepals of a buff colour suffused with pink, the petals, which are very much broader with undulated margins, being of a soft rose-lavender; the lip is of an intense maroon-purple shading to light purple on the margins. The sepals and petals of the variety *F. Sander* are of a dark red-crimson tint. The massive labellum is of an intense bright crimson dashed with purple running to the column base. The rich purple apices of the side lobes stand well up; the remaining area being sulphur yellow and rose on the inside, and white shaded with rose and crimson on the exterior. In addition to those bearing distinctive names, there are many forms which in any other collection would be considered worthy the honour of varietal names.

ARGUTUS.

WORK FOR THE WEEK.

LELIO-CATTLEYS AND THEIR HYBRIDS.

The season has now arrived when judicious admittance of sunshine to this section of Orchids is of the utmost importance, preparing them for the dull, damp, and foggy days of winter, when so many that are apparently well grown collapse. During the past summer we have had ideal weather for these plants, so the growths produced are much firmer in texture than last year, yet much remains to be done to prepare them for the coming winter. When the compost used contains leaf-soil it is even more necessary to mature them well. The growths are now at various stages, so it is desirable to congregate those that have finished growing to one part of the house, so that more sunshine may be allowed to reach them than would be good for those not so far advanced. The supply of water needed by those that are approaching full development is much less than by those in full growth. Most of the *Cattleyas Mendelii*, *Mossiae*, and *Schröderae* are still growing, and every encouragement is needed to hasten them. The autumn-flowering *Cattleya labiata* should be given as much sun as is possible without causing injury to the leaves. After the flowers are cut off trouble often arises from a rot setting in, which generally causes the loss of the leaf and sometimes the bulb; this is reduced to a minimum if they are properly ripened. *L. pumila*, *L. praestans*, and *L. dayana* should have a free supply of water till the flowering season is past. No further shade need be given to *L. anceps*.

The beautiful *L. crispata* now in flower only requires enough water to prevent shrivelling till growth again starts. *L. Perrinii* may be treated

likewise; also *C. gaskelliana* and *C. Eldorado*. Many plants of *Cattleya gigas* are now emitting roots from the new pseudo-bulb, offering the best time to repot or renovate the surface material. After potting they will require very little water until growth starts in the spring. *C. aurea* and the lovely hybrid from these two, *C. hardyana*, should also be seen to as regards potting after the flowering season is over if they emit new collar roots. I would not advise repotting this or any other *Cattleya* or *Lelia* at this season if new collar roots are not visible. These hybrids should be repotted when new shoots are being emitted.

By the time the middle of October is here I like to see the deep green colour of the leaves changed to one of yellowish green; the colour will soon be restored if the plants are well rooted when the dull short days are here, although the sun changes the colour for a time, it will help to prevent disease. Give air, especially bottom air, freely, and during the morning some top air will be beneficial. Whenever the days are dull and damp a fair amount of artificial heat is necessary, and rather than take off the air increase the fire-heat to maintain the temperature, which should be 67° early morning, 70° at night when the outside temperature is above 45°, rising when sun is admitted to 85° or 90°.

Gatton Park Gardens, Reigate.

THE KITCHEN GARDEN.

EXPERIMENTAL WORK IN THE POTATO FIELD.

BURGOYNE'S FARM is about five miles from Cambridge Station and three-quarters of a mile from Histon Station, on the Great Eastern Railway. The farm, some 140 acres in extent, is held on lease by the Agricultural Department of the University of Cambridge, and is conducted by the University Professor of Agriculture (Professor Middleton), assisted by a competent staff of scientific experts, Mr. Henshaw being the resident manager. When the farm was taken in hand, four years ago, it was in a low state of fertility and overrun with weeds, so that the farm was one requiring both careful cultivation and liberal manuring. The improvement in the four years has been immense, for the crops are good and the land is clean. Much experimental work is being carried out with pretty well every farm crop—in making selections, hybridising, manuring, and keeping careful notes of results. A very interesting pamphlet of some twenty-five pages, descriptive of the work done, is published by the Agricultural Department.

My objective was the Potato field, and under the guidance of Mr. Henshaw we moved from plot to plot, Mr. Henshaw giving a lucid description of the management, manuring, &c., of the plants, and where the seed was obtained from. Mr. Henshaw, like most Potato growers, believes in a change of seed, and here we see Scotch and Lincolnshire fen seed in its first, second, and third seasons growing side by side. After three years the benefit disappears, but the result the second year is considered equal to the first. In the trial or test-plots some sixty varieties, or so-called varieties, have been planted. There will probably be some weeding out in the future of the varieties which are so much alike as to appear identical with others in cultivation. Each plot is one-tenth of an acre in extent, and no variety is permitted to have an outside row. The manuring was the same for every plot, and consisted of 15 tons of farmyard manure and 5 cwt. of a mixed artificial manure per acre. The artificial contained 97 lb. of sulphate of ammonia, 56 lb. of nitrate of soda, 28 lb. of bone-meal, 290 lb. of superphosphate, and 98 lb. of sulphate of potash. This mixture was calculated to supply 30 lb. of nitrogen, 50 lb. of phosphoric acid, and 50 lb. of potash per acre, at a cost of about 33s. per acre. The yield and quality of the variety is the chief point to which attention is being given, but the

effects of cutting the sets and of sprouting them in boxes is also being tested, and it will be interesting to note results when the crop is lifted and weighed. The plots are in parallel lines, the rows 27 inches apart, and the sets 14 inches apart in the rows. The manure was placed in the drills before planting, and the Potatoes were planted on April 20, 420 sets in each plot. The sets were all prepared beforehand, and were as uniform in size as possible. A very few of the largest sets were cut. A further test in six separate plots is being carried out to show the effect of planting sets of different sizes, each being accurately weighed. This test will be interesting, but results cannot be known till the crop is lifted; at present there is very little difference between the different plots. These plots were planted on April 15.

Sixty varieties of Potatoes in one large field when in flower is a very interesting sight. And there is more variety in the colour of Potato blossoms than one would be led to expect who only grow a very few varieties. The flowers of several of the newer varieties are much brighter, and have tints and shades not found in the old sorts. Of course all the varieties are not flowerers, as the buds of some of the second early and early kinds drop off. But one thing which appears noticeable in the new varieties is the lack of pollen on the anthers. Of course there is pollen among some flowers, and Mr. Henshaw was on the watch for its discovery; but in a season like the present one might have expected to find every flower in a very perfect state.

One of the objects I had in view was to ascertain the best kinds of Potatoes for general planting, and in discussing this matter with Mr. Henshaw I laid special stress upon this point. Of course when all the crops are lifted further knowledge will be gained; but at present Mr. Henshaw speaks in favour of the following varieties. As first earlies there is at present nothing superior to Duke of York, Sir John Llewellyn, and Sutton's Ninetyfold. Of these Ninetyfold is the heaviest cropper, and the quality is good. Duke of York is very handsome, good cooking quality, and early; the only fault is its yellow flesh, and this would not be considered a fault where the quality is so good. Sir John Llewellyn is very highly spoken of by Mr. Henshaw.

In second earlies Findlay's British Queen is first, and Beauty of Hebron is, I hear, in the running. For maincrop at the present time there is nothing equal to the Factor (Dobbie's). It is a cross between Up-to-Date and Sutton's Abundance, and has the good quality of both parents. This is certain to be largely planted for the next ten or twelve years, or until it wears out and is superseded by some other kind not yet developed. But according to present knowledge Sutton's Discovery is the Potato of the future. It is very robust in constitution, an excellent cropper, and of good quality, and it is distinct from all other varieties that I am acquainted with. One has only to examine its growth and take note of the fibre in its haulm to be convinced of its disease-resisting energy, but the stock is yet limited. Other promising varieties are Findlay's Goodfellow, Fidler's Charles Fidler, Cramond Blossom, and General Buller.

In addition to the sixty varieties of Potatoes in the experimental plots, there are large numbers kept under observation, and are carefully rogued so that pure strains may be obtained. These include half a dozen kinds from America, of which particulars will no doubt be given in future editions of the farm pamphlet. At present all the plots are quite free from the usual disease, though in some plots of the less robust varieties there is evidence of the disease known as the curl. Mr. Henshaw thinks this is spread by want of care in selecting the seeds, and no doubt he is right. These curled plants produce only small Potatoes, and these small tubers are too often sold with the seeds. To stamp this disease out the curled plants should be treated as rogues and lifted now, and not mixed with the bulk of the crop. I have long been of opinion that the sets for planting should be selected from the most prolific roots when lifted, and kept by themselves. This matter will, no doubt, receive proper attention.

Much good work has been done during the four years the farm has been in the hands of Professor Middleton and his staff, and the future is full of promise. E. HOBDAV.

Cavendish Park Nursery, Cambridge.

P.S.—There are apparently two King Edward VII.'s in the field. At present my opinion of them is not altogether favourable. We must wait.—E. H.

SALT IN THE KITCHEN GARDEN.

DR. GIERSBERG of Berlin, a well-known German agriculturist, has just published an interesting note which calls attention to the question of the part played by sea-salt in land manuring. M. Grandeau, who analyses and comments upon this note in *La Journal d'Agriculture Pratique*, reminds us that so

manure has up to the present given scarcely any results. Nevertheless, Dr. Giersberg has had his attention called to the use made of salt by a certain number of gardeners, who say they have obtained excellent results in the cultivation of such vegetables as Cabbage, salads, Asparagus, &c. According to them the salt notably improves the quality of the crops. These gardeners have remarked also that salt given to the soil acts favourably upon fruit trees by increasing the flavour of the fruit. Can the salt, which does not act as a manure, act indirectly upon the vegetation? Does it facilitate the diffusion of the fertilising ingredients into the lower depths of the soil? We do not yet know. If it is so, plants with deep roots and fruit trees would benefit from this action. Cultural experiments undertaken in this direction at the agricultural station at Munich have shown that in lands to which marine salt was given the greater part of the vegetables not only developed much more rapidly, but they were also much more tender and of better flavour. M. Grandeau concludes that it would be to the interest of the owners of gardens to repeat and multiply these experiments.—*La Revue Horticole.*

ANEMONE ALPINA.

THE Alpine Windflower is one of the most handsome and distinct members of a small section of the genus *Anemone*, to which has been given the name of *Pulsatilla*, the distinguishing feature of which is that the carpels of the different species composing it have feathery tails, while those of the true *Anemones* have tails which are not feathery. An inhabitant of the mountain meadows of Central Europe, from Northern Spain to Transylvania, it is a very variable plant, sometimes only a few inches high, but reaching a height of 2 feet in other places, and even more under cultivation. The leaves, which appear before the flowers, somewhat resemble those of Parsley. From an involucre of similar

leaves arise the large flowers, which are white in the typical form. The number of sepals composing the flower is usually six, but this is often exceeded, as seen in the illustration, which is from a photograph taken in the Alps, and in which some of the flowers show seven or eight parts. A plant worthy of a place in every garden, it is not difficult to establish, requiring only an open, moist situation in sandy loam. Seeds should be sown as soon as they are ripe in the autumn, when they germinate readily. It is best to sow them in a prepared bed consisting of sandy loam and leaf-soil, so that they may be left for a year or two before

planting out in their permanent positions. This work is best done in the spring. After the flower is over the fully-developed heads of silky-tailed fruits are quite ornamental. *A. sulphurea* is a yellow-flowered form, which sometimes ranks as a species. W. I.

GARDENING OF THE WEEK.

FLOWER GARDEN.

PROPAGATING BEDDING PLANTS.

WITH the exception of such comparatively hardy plants as *Calceolarias* and *Gazanias*, all cuttings of summer bedding plants should by now be inserted. If any shortage does exist this should be remedied as quickly as possible, commencing with *Heliotropes*, *Alternantheras*, *Colens Verschaffeltii*, and similar plants which are killed by the slightest frost.

Before it is too late the *Begonia* beds should be gone over, and those especially good, as well as the poorest forms, should be given distinctive marks. Unless the flowers are unusually large, the plants which produce drooping blooms should be classed as second rate, to be finally discarded in favour of the more showy erect flowering forms. *Begonia semperflorens* does not come quite true from seed, and these will also require marking. The red-foliaged variety *atropurpurea*, alternated with *Chlorophytum elatum variegatum*, edged with dwarf *Begonia semperflorens*, and having a few dot plants of hybrid *Abutilons*, makes a most effective and lasting bed for autumn display. Cuttings of this *Begonia* will still root readily if made at a joint having a leaf, and placed in a cool shaded pit.

DAILIAS.

Many kinds which do not possess long flower-stalks require to be relieved of a quantity of foliage to enable their flowers to be seen. The waterings with liquid manure should be continued, and at the first opportunity inspect the plants to see that they are correctly and securely labelled.

EVERLASTINGS.

If required for winter use the blooms of *Helichrysums*, &c., should be cut while the flowers are in the bud stage, and hung up in small bunches, heads downwards, in an airy shed to dry. Growth of *Physalis Franchetti* will retain their "lanterns" better if cut and placed in water until the lower leaves turn yellow. Then take them out and suspend as with *Helichrysums*.

SWEET PEAS.

Unless the soil is very cold and heavy, a sowing at the present time will produce plants which, in the Midlands and southern counties, will safely pass through nineteen winters out of twenty, and produce earlier and better flowers than those obtained from spring sowings.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

CYCLAMENS.

ALTHOUGH these plants enjoy the cool, moist evenings at this season, with the frame lights open, it will soon be too cold and damp for them to remain longer in the cold frame. Light, with a moderate amount of fresh air during favourable weather, is what they require, as then their leaf-stalks remain short and the flowers will rise above the foliage. Generally the seeds from which plants for another year are to be raised have been sown, and in some instances the young plants are well through the soil; but still from seeds sown now plants can be raised that will with care grow into a useful size by flowering time. Plunge the seed-pans in a temperature of 60°, and encourage germination by placing squares of glass over them to check evaporation and shade them.

THE ALPINE WINDFLOWER (*ANEMONE ALPINA*) IN THE ALPS.

far two points have been ascertained: (1) That the presence of chloride of sodium in the soil, as soon as the degree of saltiness is more than a very slight trace, is hurtful to nearly all plants. Cultivation is not possible in lands naturally salt until after the removal of nearly the whole of the salt by repeated washings; the operations for removing the salt are long and costly, and do not always succeed. (2) That chloride of sodium is absent from the ash of the greater part of cultivated vegetation, an absence which is proved by analysis. Soda is never met with in plants, even in minute quantities, and direct experiments show that, in spite of the chemical analogy of the two bases, it cannot take the place of potash. As a general thing, it may be said that the use of sea-salt in

SALVIAS.

While in the open air *Salvias* appear seldom to make very much progress, but directly they are placed under glass their foliage begins to develop. Growth that is formed in a cool, light, and well-ventilated structure is that from which to expect good flowers of the best colour, and with the pots full of roots a little stimulant may be given to assist the development of the flowers, and for the purpose there is nothing better than the liquid made from guano and applied at moderate strength.

BROWALLIA SPECIOSA MAJOR.

Plants still in cold frames must be removed to the cool house, where, if given a position near to the glass, they will make a steady but sturdy growth, and in consequence will flower abundantly. Apply to their roots weak, and often, a liquid made from guano.

BEGONIA GLOIRE DE LORRAINE

which from now to the end of October generally will grow stronger and freer than at any other season, may be assisted to do so by sprinkling a little of Clay's Fertilizer over the soil on the surface of the pot. A liquid made from cow and sheep manure should occasionally be applied, as well as soot-water. Plenty of moisture is necessary, and should be created by syringing, not the plants, but the paths and stages of the house, and a temperature of 55° should be maintained.

FREESIAS.

The earliest potted of these should be looked over, and if necessary be removed from the plunging material. Often the earliest of these get spoiled through being left too long in the plunging material, the growth afterwards remaining delicate and unable to produce good strong flower-spikes. Soot-water in moderation is a capital stimulant to apply to the roots in the earliest stages, but as growth advances liquid made from cow and sheep manure will be necessary. J. P. LEADBETTER.

The Gardens, Tranby Croft, Hull.

FRUIT GARDEN.

VINES.

LATE Grapes should be assisted in every possible way so as to have them thoroughly ripe by the end of the month, as they will then keep better during the winter. Keep the laterals closely pinched to allow more light and air to reach the bunches. Do not allow the inside borders to become dry, thoroughly water when necessary, and mulch afterwards. Where Gros Colmar is grown in a house by itself more heat should be given than is required for other late Grapes. The weather has been most favourable lately for obtaining good quality in this Grape, as it almost requires Muscat treatment.

MUSCATS.

Muscat Grapes which are now ripe and well coloured should have the temperature gradually lowered and less atmospheric moisture. A dry air is necessary, especially in dull or wet weather. Remove decayed berries as soon as they appear. In succession vineries where the Vines have been cleared of fruit and the foliage is changing colour they will be all the better for another thorough washing with the garden hose. Inside borders should also have a good soaking of water, as at this season of the year they are sometimes overlooked until they become too dry, and extreme dryness at the roots is not favourable to the ripening of the wood. Young Vines which were planted last spring will require plenty of light and air, and the lateral growths must be removed. Any planted later may be encouraged to grow for a short time yet, and will be assisted to ripen by plenty of fire-heat and air.

EARLIEST VINES.

The wood will soon be ripe, when the Vines may be pruned and cleaned and the house washed and made ready for starting. Mealy bug is a formidable enemy to deal with. To eradicate it every

part of the house, walls, and woodwork should be well scrubbed, the woodwork painted, and the walls washed with hot lime. Remove loose bark from the Vines, and especially from round the old spurs, care being taken not to injure the young buds. Well wash the Vines two or three times with a strong solution of Gishurst Compound (8 oz. to the gallon), and stop up any holes with the pure compound. By this means and persistent attention in the spring this pest may soon be reduced. Great care must be taken to remove the old mulch and all loose soil from around the stems of the Vines before top-dressing with any fresh compost. If the Vines are clean a good washing with soft soap will generally prove sufficient. Great care should be taken when it is necessary to place plants in vineries to see that they are clean. *Impney Gardens, Droitwich.* F. JORDAN.

KITCHEN GARDEN.

WINTER CROPS.

THE weather in this district is again very unsettled, cold winds with very heavy showers, but it may be called "growing weather," and winter crops are making rapid progress. Difference of opinion exists as to the advisability of earthing up these crops. In light soils it would be an advantage and, also in wind-swept gardens. In damp gardens Broccoli should always be earthed up, as this affords protection from severe frosts. The soil will be in the most workable condition after rain, but the leaves should be dry before work is commenced. See that the soil is not drawn into the centre of the plant. If spring Cabbage has not been got in the first planting should be done at once, choosing a dry day to go on the ground. These may be planted rather closer than summer crops—20 inches between the rows and 15 inches between the plants. Brussels Sprouts are showing signs of being a good crop. In cases where they were planted late or are on poor land they should be given applications of liquid manure or some artificial fertiliser sprinkled on the ground, which will be washed in and be of much benefit.

WINTER SPINACH.

The sowing made in early August will, perhaps, be too far advanced to stand the winter. They should, however, be thinned out to several inches apart. This will provide Spinach into the winter months. As plots in the kitchen garden are now becoming vacant, another sowing should be made at once on good land. This will be more likely to stand the winter should the earlier sowing become too large. Although strong plants are necessary to stand severe frosts very large and soft growth is not desirable. For the last sowing choose as warm a place as possible. If the state of the ground permits it should be trodden over before sowing. The drills should be 15 inches apart and the seeds sown not too thickly.

OTHER SOWINGS.

Lettuce may still be sown on a sheltered spot, and if given some protection in severe weather they will come in useful for planting out in early spring. All the Year Round is, perhaps, the safest variety to sow at this date. Another small sowing of Cabbage and Cauliflower should also be made, as the earlier sowings seem likely to become too large. Very small Cauliflower plants are to be desired for wintering in frames, and if these are selected there is little danger of the plants buttoning. The larger plants may be put into a nurse-bed, and if protected in the winter will be found useful for very early planting.

TURNIPS.

It is of little use sowing after this date. August sowings will now require thinning to prevent their running to seed. Turnips ready for use may now be lifted and stored in a cool place. There should be sufficient of these to maintain a supply until the winter varieties are ready for use. Swede varieties should be thinned to 1 foot apart or the roots will be very small.

GENTIANA CRUCIATA

[TO THE EDITOR OF "THE GARDEN."]

SIR,—With reference to the note in your issue of the 6th ult., page 87, I have much pleasure in sending you seeds of *G. Cruciata*; perhaps you might care to distribute it to applicants wishing to try and naturalise it in suitable places. [Certainly.—Ed.] *Gentiana Cruciata* is fairly plentiful in this neighbourhood; it is very welcome, coming into flower in July, thus forming, as it were, a "stepping-stone" between the spring and the autumn-flowering species, and, like all the different *Gentians*, it possesses quite an individual beauty of its own. It is, in fact, a very pretty plant, with its heads of pleasing cruciate flowers of Cambridge blue. The flowers, each nearly half an inch across, are thickly packed together to the number of twenty or more in one terminal head, a few more also springing from one or two axils of the next adjoining leaves. The seeds germinate very freely, and I fancy such positions as the lady who found the plant describes so happily as "just on the outskirts of a wood," on chalk downs, would be admirable. Here the plant grows on shallow calcareous loam, hard as a brick, but exceedingly well drained, and apparently always "near the outskirts of some wood," but nevertheless fully exposed to the sun, in very dry places in fact. In the Bavarian Highlands, between Reichenhall and Berchtesgaden, I have lately also noticed its bulky seed-heads in quantity from a distance. Success with a few plants among the grass would doubtless ensure its further spontaneous propagation, for, like all *Gentians*, it annually ripens a large crop of seeds, if some means are adopted to prevent its pretty flowers from being cut off prematurely. Any attempt, without the aid of a pickaxe, to uproot an established plant would prove futile on account of its deep root hold. E. HEINRICH.

Planegg, near Munich, Bavaria.

THE SCARBOROUGH LILY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The modern gardener has such a long list of available plants at his command, each one of which possesses some particular charm, that there is a real danger of his forgetting some of the old favourites of a generation or so ago. One of the most worthy of these neglected ones is the Scarborough Lily (*Vallota purpurea*). Although the *Vallotas* cannot boast of that wonderful diversity of colour which is seen in the *Hippeastrums*, the glossy red blooms of the hardier plant possess all the grace and elegance of the true *Amaryllids*.

In the south and south-west of England almost a hardy plant, ordinary cool greenhouse treatment will more than satisfy the *Vallota's* requirements. But though easy to grow many people find that their plants are often very chary of blooming. The cause of the trouble is more often than not that too much attention is paid to repotting of the bulbs, with the consequent disturbance of roots. Now, *Vallotas* simply hate being unsettled, and repotting should only be resorted to at the rarest intervals. As a matter of fact the more pot-bound they are the better they seem to bloom. Far better than a removal is the occasional application of a top-dressing of fresh soil. Propagation is readily carried on by means of the small offshoots which are constantly appearing. These should be invariably removed from the parent bulb as soon as they are large enough to be handled. Potted off into small pots they will soon grow, and may be shifted in the spring into 5-inch pots, in which they will bloom. The best soil for *Vallotas* is a mixture of loam, leaf-mould, and sand. It is important in potting the plants that they should be placed very firmly in position, the soil being closely pressed around the bulb. After the plants have bloomed in the autumn, some care should be

exercised as to watering, for although Vallotas must not be dried off yet the resting period should certainly be marked by a lessening of the supply of moisture. The sorts of Vallotas cannot be said to be many, but a rather striking hybrid, with vermilion flowers, *V. hybrida*, between *V. purpurea* and *Cyrtanthus sanguineus*, has been introduced. Perhaps the most distinct form is *V. eximia*; this has red flowers, with a delicate white throat.

Reading.

P. LEONARD BASTIN.

TORENIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—These soft wooded plants have been for several years almost lost to sight, and at this season of the year greenhouse flowering plants are none too plentiful; therefore the cultivation of such as these, that will provide a bright display with only a season's labour, are too valuable to be neglected. *Torenia*s last long in perfection. Many people would grow them if it were better known that plants can be readily raised from seed sown in gentle heat in early spring, or their increase can be effected by means of cuttings rooted in early autumn. If 5-inch or 6-inch pots are well drained, filled and pressed firmly with a sandy compost with a quarter of an inch of sand on the surface, and the cuttings dibbled in around the sides of the pots and placed under bell glasses, they will, if due attention is paid to spraying them and keeping the glasses wiped out night and morning, root readily. When well rooted they should be potted singly into 4-inch pots, and after making a start should be kept pinched and induced to become bushy. When the pots are filled with roots the plants should be shifted again into 6-inch pots, and, if larger plants are required, may be again moved into 7-inch, 8-inch, or 10-inch pots. Cuttings inserted in spring make handsome plants for 5-inch and 6-inch pots, and may also be flowered during the summer months. In winter they will require intermediate temperature, but in summer a cool house free from draught will suit them. *Torenia*s may also be grown in hanging baskets. Four or five plants, if allowed to hang gracefully, will in a very short time completely cover the basket with their beautiful blue and purple blossoms. When the pots are full of roots, and, in fact, while the plants are in flower, they are benefited by weak applications of manure, and by constant feeding will remain in bloom for a considerable time.

Stanmore.

C. J. ELLIS.

LILIUM TESTACEUM GROWING WILD

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I read in "Lilies for English Gardens" that *L. testaceum* has not been found wild. It may interest some of your readers to know that five years ago I was collecting small alpine plants on a hill above Ragatz in Switzerland, and came upon some plants in seed, which were obviously Lilies, but unknown to me in their then condition. I brought home some bulbs, and planted them with my other alpine plants in my very sandy, stony garden in Kent. For two years they put out leaves, and the year after flowered. They are now a very fine clump of *L. testaceum*, quite unmistakably. At Ragatz they were very short, and growing singly and in small clumps, but not as though they had been cast out of a garden. Besides that, they were high above the village, with no houses near. I thought that this might interest you, as this Lily seems mysterious in its origin.

Bickley Vicarage, Kent.

NORA CARROLL.

THE SOAPWORT (SAPONARIA OFFICINALIS).

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In some parts of England this Soapwort occurs plentifully, and one may frequently see the double form in the shape of spreading masses in cottage gardens. There is, however, a variety of it that is infinitely superior. It bears flowers of a very bright pink, which are produced with the utmost freedom, and is altogether a fine, handsome garden

flower. I first made the acquaintance of this variety several years ago. Happening to pass a Surrey cottage garden I saw a mass covering some square yards. The display was impressive, even from some distance, and it is worth noting that it was growing in that miserable sandy soil, of which there is far too much in this county. This Soapwort is, indeed, one of the finest things for covering the ground where other things die out. It is good for covering the soil under evergreens where a fair amount of light comes, but where the soil gets parched up in summer. I am told that it is largely used in this way in Hampton Court Gardens. For very small gardens, or for borders where choice things are grown, I do not recommend it, but it is one of the finest things we have for the wild and woodland garden, where it can ramble at will and do no harm. This *Saponaria* is truly a choke-weed plant, and once get it established it will smother even Couch Grass.

J. CORNHILL.

LILIUM GIGANTEUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I enclose a photograph of *Lilium giganteum*. I purchased the bulb six years ago, but I think it

LILIUM GIGANTEUM IN AN EXETER GARDEN.

was kept too dry and sheltered by shrubs for the first four years. I transplanted it to a more exposed bed, and it grew apace.

FRANCES SANDERS.

The Rectory, Whimple, Exeter.

APRICOTS FAILING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Taken altogether, the Apricot is probably the most disappointing of wall fruits grown in this country. That the trees will grow satisfactorily and produce healthy foliage is no criterion that the fruits will ripen up as they should do, and this is where the failure with many lies, especially in the more northern parts and on cold soils. Given a warm sandy or loamy soil and taking care that the requisite amount of moisture is applied during the summer months, also growing the trees on a suitable aspect for the district—as even in some parts they succeed better on a west than a south wall—then Apricots may be ripened up well with the ordinary attention generally bestowed upon them. This, however, is very different to that which obtains on cold clay soils situated at high eleva-

tions, even when given a southern aspect, as, unless for cooking, it is almost useless to attempt to grow them. The Apricot, taking the fruits individually, grows at Stourport to as large a size as I have ever seen any, and this on a western aspect; but the soil being cold and the garden at a comparatively high altitude, the fruits ripen up very indifferently. Thinking to overcome the difficulty, the trees were all lifted four years since and replanted on slightly raised mounds, the border being also well drained and the greater part given up to the roots. Anyone would think that the Apricot would thrive almost anywhere, seeing that reference is often made to the trees that used to be seen against cottage walls and outbuildings. Certain it is that the branches and the roots of such trees had but little attention, but yet we are led to suppose they thrived amazingly. In those cases where they did succeed, and the aspect they were planted on was right, it was entirely owing to the soil being suitable for them. Given a suitable soil and a good aspect, then Apricots may succeed well when given the requisite attention. Certain it is that on light soils the trees undoubtedly collapse from the want of sufficient moisture. The roots of Apricots being naturally of a fibrous description, it is not in their nature to ramble far to seek nutriment, and with the borders, as they often are, cropped up to within 2 feet of the wall, and this space trodden as hard as a road, little moisture naturally can be expected to reach them. Not only is water needed up to the gathering of the fruit, but also during the month of September. The dying off suddenly of the branches is difficult to account for, for even under the best treatment a branch will suddenly collapse. In some cases it is attributed to want of moisture, the action of the frost rupturing the sap-vessels. Hard pruning of gross shoots which predisposes them to gumming is also given as a reason. I am also of the opinion that in the case of young trees the evil is laid in their earliest existence, as it is generally at the parts where the strong shoots are cut back to form additional branches that the first symptoms of decay are seen.

Y.

PLANTS THAT NEED CAREFUL HANDLING.

(Continued from page 162.)

ANACARDIACEÆ.

AMONG the best known of the Poison Ivies of North America are the following:

- (4.) *Rhus radicans*, Linn. The Poison Ivy. (*Rhus Toxicodendron*, non Linn.)
- (5.) *Rhus diversiloba*, Torr. and Gray. The Poison Oak.

(6.) *Rhus vernix*, Linn. The Poison Sumac or Poison Elder.

The best account of these plants known to me is that by V. K. Chesnut.* *R. radicans* is best known, and has formed the subject of a research, Dr. Franz Pfaff of Harvard having shown that the poison is a non-volatile oil. The poison is destroyed, as Pfaff has shown, by an alcoholic solution of acetate of lead (sugar of lead). It is recommended not to use strong alcohol, but alcohol of 50 per cent. to 75 per cent. To this the powdered sugar of lead is added until no more will easily dissolve. The milky fluid should then be well rubbed into the affected skin. The itching is at once relieved and the further spread of the eruption is checked. "The remedy has been tried in a large number of cases and has always proved successful."

There is an excellent article on "The Poison Ivy—a Dangerous Plant," by the Earl of Annesley in the Journal of the Royal Horticultural Society, and a lengthy digest of it in THE GARDEN of March 14, 1903, page 174. The eczema-producing nature of this plant is well described, a number of striking instances being cited.

In the Botanic Gardens, Sydney, we have a plant of it growing on a stone wall, out of reach of

* "Thirty Poisonous Plants of the United States."—*Farmers' Bulletin*, No. 86, of the U.S. Department of Agriculture (1898).

visitors. It occasionally requires pruning, and the pruner generally protects himself with leather gloves. In the course of years we have found some men immune to its effects, while others are exceedingly sensitive. In fact, we cannot say, except as the result of experience, whether a man will be affected by it at all.

LEGUMINOSÆ.

(7.) *Castanospermum australe*, A. Cunn. "The Black Bean."—This well-known furniture timber of New South Wales and Queensland has, like the Red Bean (*Dysoxylon Muelleri*), been accused of injuriously affecting the health of workmen.

MYRTACEÆ.

(8.) *Eucalyptus maculata*, Hook. The "Spotted Gum."—In parts of Queensland timber getters and sawyers who handle Spotted Gum are sometimes affected with a rash called "Spotted Gum rash." I asked a number of timber experts: "Do you know any district in which this skin complaint prevails, and can you furnish any particulars in regard to it?"

Most questioners never heard of it, but Mr. A. Voge, Mt. Douglas, Paterson, N.S.W., reports: "Spotted Gum rash prevails here. Some are affected more than others. One of my neighbours that worked with me in the bush for years felt its influence if only working beside a Spotted Gum; to work one up was out of the question. If persisting in doing so he would itch, and afterwards break out in pimples. Every occasion he got affected more; at length had to sell his selection on account of it."

(9.) *Eucalyptus hemiphloia*, Fr. M. "White or Grey Gum."—I have heard on one occasion of this timber causing a rash in a man, or at least of a rash being attributed to this timber.

(To be continued.)

NURSERY GARDENS.

CARNATIONS AT EDENSIDE.

SO far as popular favour is concerned the Carnation is now admitted to be second only to the Rose, and one can hardly wonder at it after seeing the many beautiful varieties that Mr. James Douglas has in his Surrey nursery at Great Bookham. There are colours and forms to suit the most fastidious, and those who take the culture of Carnations seriously should not fail to pay a visit to Edenside. House after house is filled with plants that either are in full bloom or else are ripening seed; there are selfs, fancies, yellow ground Picotees, white ground Picotees, as well as Malmaison Carnations, and they are the very best varieties that can be obtained. *Nisi bonum* is Mr. Douglas' motto so far as his Carnations are concerned; he rigorously rejects all that after due trial prove not to reach the high standard that he endeavours to maintain. And this is the reason that a packet of seed saved by Mr. Douglas produces such a harvest of vigorous, free-blooming plants of excellent varieties.

Interest always centres in new sorts, so when recently looking through Mr. Douglas' Carnations we were specially attracted by the latest introductions. Daffodil was pointed out as a lovely yellow self, the best of all this class. It has large, handsome, clear yellow blooms. Until its advent Cecilia has considered the best yellow self, but Daffodil has surpassed it in the judgment of most growers; it won the first prize in 1903 for the best six blooms of any yellow self Carnation. Francis Samuelson is another very fine new sort. We remember seeing it for the first time at the York show in 1903, where it gained a first-class certificate; since then it has had three more. It is undoubtedly the best of the apricot-coloured varieties; the flowers are large, full, and of faultless form. It is highly recommended either for greenhouse or border culture. Glowworm will please those who are fond of a bright flower; its blooms are rich scarlet, and it is sent out as an excellent border variety. It received an award of merit at the Holland House show this year. Mrs. Walter Heriot is a very fine

yellow ground Picotee with a good reputation, for it was the premier yellow ground Picotee in 1902 at London and in 1903 at Birmingham. It also has received more than one first-class certificate. Chloris is a lovely thing, a delicate pink self, the colour of the variety Duchess of Fife, but with larger flowers and of freer growth; a useful border Carnation. Etna, a fine scarlet self, although sent out a few years ago, is still very scarce; it has twice won first prize at the Midland show as the best self. Duke of Norfolk, a large and handsome scarlet self; Banshee, lavender, flaked with scarlet; Bridegroom, pink self, very large; Kaffir, crimson-marone, an excellent border variety; and Molly Maguire, a yellow ground fancy, the petals flaked with rose (first-class certificate), are other good new ones.

There are many very fine sorts among the general collection of varieties, but it would be useless to give a large selection here, for Mr. Douglas is always glad to do that. We might, however, mention just a few that we thought particularly fine. Chanticleer is a rich yellow fancy, heavily marked with rosy red; Hidalgo is a deep yellow, heavily marked with deep red and marone; Montjoy is a new large purple that is sure to become a favourite; and the same may be said of Midas, considered by Mr. Douglas to be a very handsome Carnation, the colour deep orange-buff, suffused with scarlet. Wild Swan is a lovely white variety with large and handsome blooms, one of the best of whites. For a white Clove it would be hard to beat Bookham Clove, a pure white Clove-scented Carnation of vigorous growth that has received an award of merit from the Royal Horticultural Society.

Of yellow ground Picotees, of which Mr. Douglas has probably the finest trade collection in the country, we saw many lovely varieties, e.g., Alcious, lemon-yellow ground, distinctly margined with purple; Borderer, bright yellow, edged with red; Gertrude, petals broad, with a heavy bright rose margin; Ladas, with well-defined scarlet edge; Voltaire, bright yellow, edged and marked with rose; and Childe Harold, a most elegant bright rose-margined flower. This variety has won the premier prize as the best bloom at the National Society's exhibition for four successive years. Mr. Douglas has collections of Malmaison Carnations, Anriculas, Tree Carnations, Pinks (among which we may mention Snowdrift and the new hybrid Dianthus Lady Dixon), German Irises, double Peonies, and Narcissi.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

HOUSING.

BY the end of the present month the whole of the plants which have been grown with the object of producing large blooms should be safely housed, and when the weather shows signs of becoming unsettled the sooner this is done the better. Frost may set in at any time, and whenever there is the least likelihood of the glass reaching the freezing point protect the upper portions of the growths, as plants which have been well grown and highly fed are susceptible to injury. Though this may not be noticeable at the time, serious injury will result if the young buds become frozen, and will be seen when the buds begin to develop.

Gales of much severity generally occur at this season, and often do a very large amount of damage to tall-growing plants, however well they may be secured, but especially so to those which have not been properly tended in this respect. It is annoying after the care and hard work that have been bestowed on them for so long to find many of the most promising tops blown off in a short space of time. The supports should be examined, and additional stout cords stretched along to prevent their giving way. Each growth will be safe if small sticks about 2 feet in length, similar to the tips of Bamboos, are well fastened with broad pieces of bast to the tops of the shoots. As to the

kind of structures in which to arrange the plants, the Chrysanthemum is fortunately not so fastidious as many other half-hardy plants, and if plenty of ventilation, both at the sides and top, can be assured, and the roof made drip-proof, good plants should produce satisfactory flowers.

OVERCROWDING.

Far too often, owing to lack of accommodation under glass, plants which have given every promise of maturing blooms of exceptional quality are spoiled by placing them too thickly together. Many are under the erroneous impression that by this time the plant has done its most important work, and, providing it can be placed under glass, even though three parts of the foliage may turn yellow and be taken away, little harm will happen; but this I am fully convinced is a most serious error, as it is just now that every inducement should be given them to retain their leaves as much as possible, and the better the plants have been grown the more will they suffer when packed too closely together. It is far better to discard many of the plants which are not likely to give the best returns, or place them under a wall or similar position where protection can be afforded. Many of these will probably give useful late blooms for decorations when the others are past. The ventilators should be left open night and day top and bottom for some time after the plants have been taken in, except when it will be necessary to close them for fumigating, and this should most certainly be done two or three nights in succession, so that every vestige of thrip and aphid is destroyed. XL All Vaporiser is both safe and effectual when used according to the instructions.

When there is any signs of rust no pains should be spared to destroy it, and I know of nothing equal to paraffin. When persistently used at the rate of one wineglassful to every four gallons of soft water, thoroughly mixing it with the syringe when using by discharging one barrel into the vessel containing the mixture and one on the plant, making certain that every particle of the foliage is touched, it will never do serious harm. Many good blooms, I am aware, have been grown when practically every leaf has been taken off; but good as these may have been, there is no doubt that they would have been much better had they been free from fungus.

WATERING.

The plants will not get so dry as when in the open, and the greatest care should be observed as to this. Examine each thoroughly, and make absolutely certain that the plant is quite ready to receive it before giving any, and when doing so fill up the pots at least twice, and this should be done as early in the day as possible.

STIMULANTS.

The plants will need assistance at this stage, but overfeeding will do more harm than good. Weak applications and often will be the safest course to pursue. Soot water and Peruvian Guano in moderation are both excellent if carefully used when the plants are grouped together under glass. Caterpillars and earwigs often do considerable damage to the florets as they begin to unfold, and each should be rigorously sought after with the lamp at night. Keep the under sides of the leaves well dusted with black sulphur to prevent mildew spreading. The Japanese varieties should be arranged separately from the Chinese if possible, and the first-named will benefit with a little fire-heat after they become acclimatised, but, on the other hand, the incurved always resent artificial heat, and well-formed flowers cannot be expected when kept too warm. Sufficient fire-heat only should be given to counteract damp, and then only when air can be admitted freely.

SPECIMEN PLANTS.

Pay strict attention to these in every respect. Plenty of air must be allowed to play freely about them, turning the plants round every other day. Manure water should be given each time the plants are dry, as these need much assistance to enable them to perfect fine blooms and carry good healthy foliage, without which there is little beauty.

LATE-FLOWERING DECORATIVE VARIETIES.

These should be kept in the open as long as possible, but means must be provided thoroughly to protect them against frost. Temporary shelters should be erected in sheltered positions, then blinds or other suitable coverings can be placed over them when needed.

Aldenham House Gardens, Elstree.

A GENERAL CALENDAR.

ANNUAL FLOWERS.

NOW is the best time to sow most kinds of hardy annuals. A large proportion of them will germinate at once, make strong plants before winter, and bloom earlier and stronger than those sown in the spring. A somewhat poor and dry soil should be chosen, but it matters very little if the soil is cold and damp, for we see sometimes on the worst of soils, and on the best alike, self-sown Wallflowers, Candytufts, Mignonette, Sweet Peas, and many other things that have managed their affairs in their own way, the seeds having been shed in July, germinated in August and September, and became nice little green bushes by Christmas, and good flowering plants in the month of May.

THE BEST FOR AUTUMN SOWING.

In the display of annuals there is the same room for the exercise of taste as in the display of any other kinds of flowers. I have found the following well adapted for autumn sowing: *Calliopsis tinctoria*, *C. atkinsoniana*, *Centaurea Cyanus*, *Cladanthus arabicus*, *Clarkia elegans*, *C. pulchella*, *Convolvulus tricolor*, *Delphinium Ajacis*, *Eschscholtzia californica*, *Leptosiphon luteus*, *Limnathes Douglasii*, *Nemophila insignis*, *N. maculata*, *Platystemon californicus*, *Silene pendula*, and *Whitlavia grandiflora*.

PENTSTEMONS.

Cuttings of these should now be put in, choosing only those varieties which show healthy growth. All those with spotted or sickly-looking foliage should be discarded. To do these well a succession of seedlings should be kept up, from which may be selected those of the best colours and constitution. From these cuttings should be raised, as they almost invariably do well the first year after being propagated direct from seedlings. They strike readily in a cold frame or under a handlight if placed on a hard bottom with about 6 inches of sandy soil. Well water the cuttings after they are put in, and keep close and shaded for a few days until they begin to callus.

FIG TREES.

Some of these have abundance of growth this season, and in most instances many more shoots have sprung up than ought to be permitted to remain. And, if not already done, it will be advisable immediately to remove a portion of their surplus shoots. Also pinch out the points of those growths that are allowed to remain. By doing this the wood will become thoroughly ripened, and the buds so well developed that a crop may be expected next year. At present much of the new growth is very tender, and if we should get a sharp winter much of this may be killed by the frost, and not only a crop lost but also valuable time.

PEACHES AND NECTARINES.

The leaves that shade the fruits should be turned aside or removed altogether, so that the fruit may be exposed to the direct rays of the sun. When the fruit is all gathered the succession shoots should be looked to, and if any of them are crowded cut back those that have borne fruit close to the base of the succession shoot. This being done let the trees be frequently syringed, and should the weather continue dry give the trees a good soaking of water.

PARSLEY.

This important vegetable should receive more attention and more liberal treatment than it

generally gets. Seed should now be sown on a border with an eastern aspect. Let the soil be good and well worked before sowing the seed. This should be in drills 12 inches apart. Cover with fine soil to assist germination, which generally takes place in from four to five weeks. As soon as the plants are large enough they may be thinned to 6 inches or 9 inches apart. This will give much better returns than if the seedlings are allowed to remain in the rows as they come up.

CAULIFLOWER VEITCH'S AUTUMN GIANT.

A sowing of this made now will furnish a nice batch of plants, which should be wintered in a cold frame or under handlights. These would make good plants for planting out in the spring, and give far better results than the smaller sorts, such as Early London, raised in heat in February.

T. B. FIELD.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

SOME RARE FLOWERS.

From the Old Parsonage, Gresford, Cheshire, Mr. Mules writes: "I send for your kind inspection a bloom of a new seedling *Rudbeckia purpurea*, which compares favourably with those at present in cultivation. It is one of the new hybrids, and, so far as I have seen, is far choicer than any that have yet appeared. I send Perry's hybrid to compare. Its diameter is 7 inches, and the colour a bright pure rose. [A very handsome flower.—Ed.] *Lychnis grandiflora* (from China), the plant figured in *Paxton's Magazine of Botany*, is a very rare and beautiful plant. You will note the salmon-coloured petals, deeply fimbriated, the bright crimson ring, and blue stamens. I send a spray of *Montbretia Tragédie*. I do not see it in our catalogues; but it is one of Lemoine's best hybrids, and is, with its large golden flowers, an admirable companion to *Germania*. Here it grows 4 feet high or more. *Phlox Lienvalli* (new) is a very pretty variegated variety, of which the white stripes are clearly marked on the edges of each petal. Here *Solanum jasminoides* does well outside, and I send you a few sprays, of which the flowers are well developed."

CLERODENDRON FETIDUM.

Mrs. Nix writes from 33, Ferndale Park, Tunbridge Wells: "I sent a few pieces of *Clerodendron fetidum* to you to-day for your table, though I fear it is not a pleasant scented flower. The rosy pink corymbs of flower are very handsome, but I am afraid it fades quickly in water. Our plant came from Cornwall, and is in a somewhat sheltered corner of a south border. It has increased very quickly, and is spreading over a large part of the border. The tallest stems are over 7 feet high. It seems quite hardy here, though we have a cold and exposed situation, and do not protect it at all in the winter."

SEDUM SPECTABILE ATROPURPUREUM.

Mr. Amos Perry, Winchmore Hill, sends flowers of *Sedum spectabile* and the variety *atropurpureum*, which is a much deeper colour and more effective. Although *S. spectabile* is a most useful plant because of its lateness, easy culture, and durability of the flowers, the colour is poor; the variety *atropur-*

pureum will meet a want, and its advent is opportune. Mr. Perry also sends a pretty new semi-double variety of *Galega officinalis*.

MUTISIA DECURRENS.

From Winthorpe, Ravelston Dykes, Edinburgh, Mr. Mowbray Watson writes: "I enclose a few late blooms of the rich orange-flowered *Mutisia decurrens*. The flowers were larger a fortnight ago. This plant has had over forty blooms this year, and has now been with me ten years. As it comes from the Chilean Andes, along with the red *Tropaeolum* (*T. speciosum*) grown all over Scotland, there is no doubt about its hardiness."

GILIA CORONOPIFOLIA.

From Banksia, Milton, Sittingbourne, Mr. C. Prentis sends flowers of this plant. He writes: "I sowed the seeds last autumn, and the plants have been in flower since early July, and they are not nearly over yet. It is very showy and valuable by reason of its late and continuous blooming. It has aroused a great deal of interest among my gardening friends."

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 3, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Names of plants.—S. Abbott.—The abnormal growth on the Oak twigs is due to a gall known as the Artichoke gall, caused by the presence of the larvae of *Cynips Quercus-gemmæ*.—C. E. F.—*Abelia rupestris*.—S. J. M. Price.—The specimen you send is *Acacia melanoxylon*. It is one of the few species of *Acacia* which produce both phyllodes and true leaves at the same time. Most of the species bear either all phyllodes or all true leaves.—C. E. F.—The Bamboo is *Arundinaria falcata*.—Charles Prentis.—*Lotus Tetragonolobus*.—Q. Q.—Probably *Origanum vulgare*; too withered to say positively.—J. A.—*Linaria origanifolia*.

Names of fruits.—G. Heaths.—1, Ecklinville Seedling; 2, Cox's Pomona; 3, Braddick's Nonpareil.—James Tizzard.—Plum 1, Early Transparent Gage; Plum 2, Oullin's Golden Gage; Pear 1, Williams' Bon Chrétien; Pear 2, Forelle (the Trout Pear). We will name the Apples and Ferns with pleasure.

Woodlice in Melon frame (B.T.).—Woodlice in frame containing Melons which are now beginning to net may be greatly reduced in number by trapping before the fruit is ripe. Procure a few small dry flower-pots, put a slice of raw Potato in each, cover with a pinch of moss, and lay them on their sides in the frame. Go round every morning with a jar of boiling water, transfer the woodlice from the dry ambush to the jar, relay the traps, and persevere. Also, lay small heaps of Lettuce or Cucumber leaves about in the frames where hot water will not reach the roots or foliage of the Melons. Examine these heaps every night, and pour boiling water over the pests when feeding. Woodlice may be prevented from doing much harm by placing each fruit upon an inverted flower-pot resting rim downwards in a saucer filled with water; or instead of the saucers of water, when the ripening fruit requires dry heat, each pot may be capped with a square of glass a few inches larger than the pedestal. Woodlice enjoy heat, a dry ambush, and solitude. Therefore, by reversing these conditions as much as possible they will be discomfited. Every effort should be made to catch and kill them, as they may attack the stems and foliage after the wholesale nibbling of the fruit has been made impracticable.

A barren Fig tree (H.).—Unless this vigorous healthy Fig was of good size when planted two years ago so far you have but little cause for complaint. Figs, you must understand, are peculiar in their likes and dislikes, and yours seems to have food which it likes, hence most likely its strong infertile condition. Does it get full sun, plenty of heat and air, and is it well drained? If not, lift bodily when the leaves are ready to fall, shorten all the strongest roots, and replant in a well-drained limited area. A poor calcareous loam, not too light, two-thirds, and old lime rubble one-third, thoroughly mixed, will make a suitable compost. Make the border 18 inches deep, resting on a well-drained concreted bottom, and not more than 9 feet super at the outset. Relay the roots near the surface, give one watering to settle the soil about them, finish off, and keep dry until February. Resume watering when the buds commence swelling. Train the main shoots 1 foot apart and shorten

others not wanted, to induce the formation of short spur-like pieces, which will show fruit freely. A greenhouse Fig should have a poor larler, but plenty of water in summer, an abundance of sunlight and air to ripen the wood and give flavour to the fruit, and complete rest through winter.

Plants for wall, &c. (E. VON SCHWIND).—The following will do well for the stonework along the margin of ponds: *Silene maritima plena*, white, double; *Lithospermum prostratum*, blue; *Arabis alpinus fl.-pl.*, white; *Campanula garganica*, blue; *C. g. alba*, white; *C. muralis*, blue; *Saponaria ocyndoides*, rose; *Polygonum Emmonit*, pinkish red; *Arenaria balearica*, white; *Ambrosia Hendersoni*, A. Leichtlini, A. graeca, *Gypsophila prostrata*, white; *Thymus lanuginosus*, *Veronica rupestris*, deep blue; *Phlox setacea* Vivid, rich rose; P. s. The Bride, white; P. s. atropurpurea, *Eriogonum macrocarpa*, large yellow; *Emphalodes verna*, intense blue; *Hemerilla glabra*, *Campanula pumila*, C. p. alba, *Helianthemum* in variety, *Saxifraga Wallacii*, white; *S. rhei* superba, pink; *S. Sternbergi*, white. Those marked * will also do for the tower, and you may add *Dianthus cæsius*, *Armeria alpina*, *Sedum spurius*, *Sempervivum*, *Wallfomentosum* (which is suitable for pond), *Achillea umbellata*, &c. All are quite hardy, and you will find quite an interesting variety. The plants are all inexpensive.

Plants for hanging baskets (STAMP).—For hanging baskets in a verandah to be effective during autumn and winter it is of course necessary to employ only quite hardy plants, and the choice of suitable ones is extremely limited. The most effective baskets for winter in such a position are Ivies, one variety in each basket, and in hanging them up alternate the green and variegated-leaved forms. There are so many varieties of Ivy that the better way will be to make a selection from a nursery, avoiding as far as possible the very strong, large-leaved forms. The baskets must be effectually lined with moss or thin turves, and in planting the Ivy in the centre take care that the soil is worked thoroughly around the roots. The longest shoots may be pegged around the outside of the basket, leaving the minor ones to dispose themselves at will. After the Ivies have made a little growth the stiffness incidental to newly-planted subjects will disappear. The soil of your border is, we should say, much too light for Carnations, but it might be made suitable by incorporating with it some heavier material. At all events it is worth trying a few, for sometimes unpromising soils give far better results than one might anticipate. Herbaceous plants that will do well under such conditions are *Alstræmerias*, *Asclepias tuberosa*, *Asters* (Michaelmas Daisy section), *Chrysanthemum maximum*, *Dictamnus Fraxinella*, *Doronicum*, *Eryngium* (Sea Holly), *Galega officinalis* and its variety *alba*, *Gaura Lindheimeri*, *Gypsophila paniculata*, *Helianthus*, *Hemerocallis*, *Iris germanica*, *Iberis*, *Linum*, *Lupinus*, *Enotheras*, *Potentillas*, *Pyrethrums*, and *Rudbeckias*. Of annuals you have the choice, among others, of *Eschscholtzias*, *Godecias*, *Larkspurs*, *Lupinus*, *Marigolds*, and *Tropæolums*. Of these last the different forms of *Nasturtium*, both climbing and dwarf, are very desirable for a hot border, as in such a place they flower far more profusely than in rich soil. For spring flowering the low-growing *Phlox setacea* and the different *Aubrietias* will thrive under such conditions, while numerous bulbous plants are also available, particularly *Hyacinths*, *Tulips*, *Daffodils*, *Scilla sibirica*, *Chionodoxas*, *Crocus*, &c. *Gladioli* will also form a bright feature in late summer.

Tea Roses upon Laxa stock (BELLBOUGHTON).—For forcing purposes we believe *Rosa laxa* would be an excellent stock for Tea Roses, and superior to the seedling Briar, but for outdoor growth nothing can surpass the seedling Briar. In some localities the seedling Briar is not a success, and in that case the Briar cutting is next best; but we should not recommend *Crimson Rambler* as a stock for Roses, although, of course, this and any other strong-growing multiflora, *Follyanthus*, *Sempervivens*, or *Ayrshire Rose* could be used, if necessary, for Tea and Hybrid Tea Roses. We saw some time since in an amateur's garden some splendid plants of *L. Ideal* budded upon *Manetti* stock, but possibly if such plants were transplanted they would fail to grow. So much depends upon locality as regards the fitness or otherwise of certain stocks. We know an eminent raiser of Roses on the Continent who largely employs *R. laxa* as a stock; his chief reason for doing so is that this stock, being so active, if budded in May, and the tops bent down to the ground, will so stimulate the growth of the inserted bud that quite nice little plants are available the same year as budded. If you are able to provide a good depth of soil for your Tea Roses, say 2½ feet to 3 feet deep, then we strongly recommend you to use seedling Briar, or Sweet Briar, as they are deep rooting and will continue to grow well into October, and thus produce the autumn blooms valued so much.

Roses on bank (LONDONER).—We presume that it is your intention to furnish the arches with some of the many delightful Roses suitable for the purpose; at all events, we should advise you to do so. But in the event of a greater variety of plants being preferred, you may, if you wish, clothe them with a selection from the fine varieties of *Clematis* now so popular, or a Rose and a *Clematis* may be planted alternately. The following Roses are all good for the purpose, and would give satisfaction: *Amée Vibert*, an old and well-known Noisette, with large clusters of white flowers; *Crimson Rambler*, known to all; *Electra*, a cross between the typical *Rosa multiflora* and *William Allen Richardson*, with pretty little flowers, yellow in the bud state and white when expanded; *Euphrosyne*, the Pink Rambler; *Félicité Perpétue*, a pretty creamy white flower; *Flora*, deep pink, handsome leafage; *Gloire de Dijon*, well known to everyone; *Longworth Rambler*, belonging to the Noisette section, with bright carmine flowers; *Mme. Alfred Carrière*, a grand Rose for arches, with large sweet-scented white flowers; *Queen Alexandra*, of the multiflora section, with pink flowers; *Reine Marie Henriette*, bright crimson; *Reine Olga de Wurtemberg*, brilliant red, semi-double, a grand climbing Rose; *Waltham Rambler*, a multiflora Rose with single pink flowers; *Waltham Climber No. 1*, bright crimson; *W. A. Richardson*, deep orange. The

variety *Fellenberg*, though not a China but a Noisette Rose, is just the thing for massing, as it is bright in colour, and flowers profusely, while a succession of blooms is kept up for some time. We think you could not do better than plant this Rose in the situations suggested.

Climbers for fence (LONDONER).—Of climbing or rambling shrubs suitable for clothing a 6 feet Oak fence the different *Clematis*, though beautiful, hide the wood but little during the winter months. A certain proportion of evergreens is necessary for the purpose, and these may, if preferred, be alternated with deciduous plants. Suitable evergreens are not numerous, yet the following will do well: *Cotoneaster microphylla*, *Berberis stenophylla*, which, though a shrub in habit, is very good for walls of the height named; *Escallonia macrantha*, *E. philippiana*, and *E. rubra*, the best three *Escallonias*. Deciduous plants would embrace: *Cotoneaster horizontalis*, *Forsythia suspensa*, *Hydrangea petiolaris* (volubilis), *Jasminum officinale*, *J. nudiflorum*, *J. wallichianum*, *Lonicera japonica*, and *Akebia quioata*. If a few *Clematis* are desired, you may plant of true species, *C. flammula* (Virgin's Bower), *C. montana*, and *C. viticella*; while garden varieties may be selected from *alba magna*, white; *Beauty of Worcester*, violet; *Blue Gem*, pale blue; *Countess of Lovelace*, lilac; *Duchess of Edinburgh*, white; *Jackmanni*, violet-purple; *Jackmanni alba*, nearly white; *Lady Caroline Neville*, French white, deeper bar; *laingnosa candida*, greyish white; *Nelly Moser*, silvery lilac, purple bar; *Star of India*, rich plum, with deeper bar down each petal.

Destroying deep-rooting weeds (H. M.).—Ploughing ground, then well harrowing it to destroy deep-rooting weeds such as Thistles, Nettles, Coltsfoot, &c., would have but a temporary result, as the movement of the plough would break the fleshy roots into many portions, and every piece would become a new plant. But in a garden ploughing is out of the question, and some good may be done by deeply forking the ground and thus picking out every piece of root possible, and, if trenched two spits deep, the work would be more effectual still for a time. But there would be a recurrence of growth the following year, though less strong, and that should be taken advantage of to keep the hoe in constant use, cutting off hard every evidence of weed growth seen. Were that done one whole season the effect would be to weaken the root growth greatly, and it is most probable that a second year's constant hoeing would kill the weeds entirely. If the roots cannot make leaf growth they must presently die away. But the hoeing must be constant, keeping down every bit of leaf growth that is seen at once. That, however, should at the first be done by weekly hoeings, and later in the season by fortnightly ones. Where arable fields have been allowed to go to ruin through weeds of the nature you name, a heavy responsibility rests on those who rent or own land, and a vast deal of what is seen in both arable fields and pastures is due to the neglect to use the hoe. In a garden such neglect is quite inexcusable. Growing weeds means ruin, but growing good clean crops always means prosperity. That is always our experience. There are few garden or field tools of more value than the hoe when freely and ably used.

Peat for Rhododendrons (A READER).—(1) The ordinary sandy peat known as "Rhododendron peat" is the kind generally used. The superior fibrous peat used for Orchids and other choice pot plants would be too expensive and not necessary. We have grown Rhododendrons in sandy loam with leaf-mould very satisfactorily. Some nurseries grow their young plants in loam; others in peat. It is better to get plants from a soil similar to that in which it is intended to grow them permanently. In any case the soil must be free from chalk or lime. (2) Rhododendron peat is sold by the ton; about four tons would probably make a truckload. Without carriage the price would be about 20s. per ton. (3) We do not know of any peat in the neighbourhood of Marlow-on-Thames. If none is found there it would be better for the nurseryman who supplies the plants to supply the peat; both could come together, and we think it would be cheaper and more satisfactory.

Arbor-Vitæ hedge (CROMWELL).—You do not say at what time the above was planted, and, as all else appears to favour success, we imagine you planted somewhat late for this particular shrub. The size of the plants and the method of preparing the trench are good. Planting should have been done quite early in October, or left over until March or early April. The above and a few others we could name are quite unsuited to late planting on heavy soils, where the root-fibres may long remain inactive. In place of the above we suggest the planting of Yew trees to form the hedge. Plants not exceeding 2½ feet high are generally satisfactory for transplanting. These may be put out in October, or, if this cannot be arranged, defer the planting till March. The Yew is a capital subject for soil such as you describe, the other plant generally preferring a lighter soil. If you care to try the *Arbor-Vitæ* again, you may, in addition to what we have said already, endeavour to place some lighter soil about the roots to afford the plants a start. Leaf-mould and road-grit freely mixed with the staple soil would greatly assist. A similar material may also with advantage be incorporated with the soil of the trench. If you do not plant before March you will ever have to guard against piercing winds, for nothing is more disastrous to freshly planted trees or shrubs. In such a case frequent syringing of the plant is highly desirable, so that the branches may remain fresh and thus more quickly promote root-action. You may improve the condition of the soil for gardening purposes generally by freely adding the ashes from burnt garden refuse, road-grit, fine ashes, or the burnt clay earth which as ballast is usually plentiful in districts where clay abounds. If you can obtain this in plenty you may, by taking the garden piecemeal, greatly improve it and generally prevent the cracking. By first making sure of the drainage and adding the grit and other things in plenty for a season or two, together with light manure in preference to heavy, a decided improvement will follow. In addition, if you employ a small fork for pricking over the surface in place of the hoe, and lightly mulch the surface with manure of the old Mushroom bed type, you will find, by working this

continually into the surface, that the soil contraction will diminish. A rough sketch like the one sent is usually sufficient.

Maund's "Botanic Garden" (ALFRED JAMES). Maund's "Botanic Garden" consists of thirteen volumes, with 312 plates; Maund's "The Botanist" consists of five volumes, with 250 plates; and Maund's "Floral Register" of two volumes, one of which is called the Auctarium.

Books on Orchids (G.).—The best illustrated books dealing with Orchids are Sander's "Reichenbachia," Williams' "Orchid Album," Linden's "Lindenia," "Orchids: Their Culture and Management." The price of the last named is one guinea (Upcott Gill), the others are more expensive. "The Book of Orchids" (Lane) is 2s. 6d. We will make further enquiries about the other one you name. Mr. G. F. Wilson died on Good Friday, 1902, and a notice, together with portrait, appeared in THE GARDEN for April 5.

Climbing Roses under glass (S. J. KNOX).—It is impossible to give these too much air or light at the present time. If the growths have been somewhat neglected lose no time in separating them while still only partially ripe, as not only will they bear shifting much better now, but they will also ripen better when isolated. The whole secret of a good crop of Roses from these extra vigorous and climbing Roses is in getting plenty of well-matured wood each autumn. You will then be rewarded with a grand show of bloom throughout the full length of each growth. In order to assist to this desirable end it is well to cut away all growth that has flowered. The sooner this is done after dowering, the more strength will the young growth that is to form flowering shoots for next season have. Keep your Roses under glass rather dry at present, so as to help mature the growths. Shading that was put on during the summer, and that has not yet been washed off by rains, should be removed.

Tigridia Pavonia (N. Y. Z.).—The above and other species and varieties of the genus are for the most part cultivated in the South of France, the Channel Islands, and other places. Natives of Mexico, South America, Chili, &c., they require protection during winter in this country, and this is generally afforded them by early autumn lifting and storing away in a place secure from frost. If carried to excess it certainly does harm. Generally, however, with good roots a fairly good flowering results in the first year, after which you may modify the drying to a large extent. If you grow the plants in large pots the latter may still retain the roots with the soil quite dry. If you cultivate them in the open ground select a sunny position. The soil should be light and rich, deep and very sandy. When matured after flowering place the roots in dry sand or soil, and avoid exposure to external influences, which is the chief cause of excessive shrivelling.

CORRECTION.—"Iris susiana at Colchester." The illustration of *Iris susiana* that appeared above this title last week was from a photograph taken at Wretham Hall, and not at Colchester.

TRADE NOTES.

WEST'S RAFFIA TAPE.

We have not seen a better material for tying plants and flowers than that submitted to us by Mr. C. E. West, Higham Hill, N.E., under the above name. The tape is a pleasing green colour and very tough; it is corrugated, which makes it keep flat and prevents its twisting, so that it cannot cut or injure the most delicate plant. Mr. West says that however tightly it may be tied it will always expand with the growth of the plant. The corrugated surface also prevents its slipping backward when tying, so it is very easy to use. On account of its colour it is much less noticeable than ordinary raffia, and the appearance of the plants is in no way interfered with. After a short exposure to the weather the green will soon lose its brightness. It is much cheaper than raffia, yet it is much stronger and almost imperishable. We think West's Raffia Tape will prove very serviceable in the garden. There are many other novelties in Mr. West's Catalogue, which will well repay perusal. Among them we may mention "The Hand Fumigator," "Sprayer," "Spray Syringe," "Powder Diffuser," "Earwig Traps," a wire mesh substitute for crocks in pots, Weed Extractor, as well as a great variety of insecticides, manures, &c. Some eighty-five pages are devoted to the description and illustration of garden requisites.

It is announced that *The Studio* will shortly publish a special autumn number devoted to the work of two of France's greatest humorous draughtsmen—Daumier and Gavarni. In these hurrying days these two remarkable geniuses are almost forgotten, yet both of them can, without hesitation, be assigned places amongst the most powerful and the most imaginative draughtsmen the world has ever seen. They were humorists of the first order—sometimes subtle, sometimes grim, and sometimes boisterous, but always humorists in the best sense of the word. Each of them at times took excursions into the realms of tragedy and pathos, in astonishing contrast to his usual habit of brimming humour, but above all things each, by the force and flexibility and the significance of his line, was a draughtsman of the very first rank. *The Studio's* special number will contain, as usual, a large number of coloured plates and photographs, as well as full-page facsimile illustrations in black and white.

CATALOGUES RECEIVED.

THE GARDEN

No. 1714.—VOL. LXVI.

[SEPTEMBER 24, 1904.]

THE AUTUMN ROSE SHOW.

THE new Horticultural Hall was crowded with exhibits and flower-lovers on Tuesday last. There were beautiful groups of September flowers, rare hybrid Orchids, superb vegetables from Lord Aldenham's garden, and miscellaneous displays, but the chief attraction was the first Rose exhibition in autumn.

It was a mild reflection of the splendour of the summer shows, and somewhat disappointing, although we were not prepared for a more imposing display. The weather in the South of England has been none too kind of late. A low temperature, drenching rains, and a wintry wind have not tempted the flowers of even the most famous of autumn varieties to expand in a way to delight the heart of an ardent exhibitor. But the exhibition was sufficiently representative to instruct those wishful of bringing the fragrance of summer into the autumn garden.

Many of the exhibits were superb, and two new Roses gained the coveted gold medal. One was named J. B. Clark, a Hybrid Tea, shown by Mr. Hugh Dickson, and reminding one of Crown Prince, the colouring being a warm velvety crimson-purple, the petals pointed, and the whole flower suggesting great possibilities for exhibition. Of quite a different class was the other gold medal Rose, which was shown by Messrs. Alex. Dickson and Sons, Newtownards, Belfast. The name of this is Irish Harmony; the flower is quite single, suggesting Jersey Beauty, soft creamy yellow, deep yellow anthers, and very beautiful in all ways; a vigorous Rose, that must be welcomed for its freedom in autumn, as an addition to the increasing roll of varieties that bloom at this season.

Mr. Hugh Dickson also showed another Rose of much beauty, and named Hugh Dickson; it is a seedling, we believe, from Grüss an Teplitz and Lord Bacon, and has large, broad, strong petals of a crimson colour. It may interest our readers to know that Mildred Grant gained the silver medal for the finest Hybrid Tea, and in the true Tea class, E. V. Hermanos was the most successful. This is a flower of delightful colouring, apricot, rose, and yellow melting into each other, and a Rose to make note of. It is not new, but not much known in gardens.

What are called "garden" Roses were very fresh and beautiful in colour, and the first prize collection, from Messrs. Frank Cant

and Co., Braiswick Nursery, Colchester, consisted of the following sorts, which indicate the Roses that may be trusted to flower freely in September, and, if the weather is warm and not too wet, far into October: Mme. Pernet Ducher, Souvenir de Catherine Guillot, Marquise de Salisbury, Augustine Guinoisseau, Petit Constant, Comtesse Laura Saurma, Mme. Jeanne Dupuy, Papa Gontier, Perle d'Or, Fairy Queen, Mme. Eugene Rene, Corallina, G. Nabonnand, Comtesse de Bardi, Irene Watts, Marie Pavie, Mme. Laurette Messimy, Safrano, Dr. Grill, Mrs. B. R. Cant, Mme. Charles, Leoni Lamesch, Gustave Regis, Rainbow, Mme. Ravary, Cecile Brunner, Mme. Jules Grolez, General Schablikine, Queen Mab, Antoine Rivoire, Killarney, and Fabvier.

The Tea, Hybrid Tea, and China Roses thrust out almost completely the Hybrid Perpetuals, which are the glory of the summer shows, but it is possible that in the future a race of Hybrid Perpetuals as sweet in scent and beautiful in colour may be raised for autumn flowering. The warm colours of this group were missed, but when we think of the tremendous upheaval in the Rose world during the past few years, the many exquisite flowers that have been raised for gladdening the garden in autumn, it is ungracious to utter one word of regret.

The Hybrid Perpetual Rose of the show was Frau Karl Druschki, and the flowers from Newtownards were as perfect as anything we have seen this year, so white and large, without any suggestion of coarseness. As this gives freely of its flowers in autumn, it is not unreasonable to suppose other colourings may be obtained in the future.

We repeat that the show was not brilliant, but as a first attempt sufficiently so to warrant its continuance. It will grow in interest to the exhibitor and general public, as new varieties or hybrids are raised with the special virtue of autumn flowering, and in such a year as the last, when the beauty of the Roses in autumn remain a pleasant memory, the competition would have been much keener, and the flowers generally of greater excellence.

It was, however, an interesting occasion, and the members of the National Rose Society should look back upon the initial exhibition with reasonable pride. Never has the fairest flower that graces the English garden excited greater interest than at the present time, when a garden is not thought worthy of the name without an almost overflowing of the most

beautiful varieties in the various sections. During the coming weeks thousands of Roses will be planted in the home gardens, and a general desire is to acquire not sorts that have a too brief flower life, but that will continue in beauty from summer until late autumn. We want more of the Dorothy Perkins type, and feel happy in the thought that the hybridist is striving to gratify our wishes.

There were several miscellaneous groups of Roses, in which the variety of sorts was as noticeable as the freshness of the flowers; but as these are recorded in our report, further reference to them is needless. The Rose show in autumn should be an annual fixture, and the National Rose Society will be wise in continuing it, if only to encourage raisers of new sorts to make September a month of Roses as fresh and fair as those of sunny midsummer days.

EDGINGS IN THE KITCHEN GARDEN.

OF what use are edgings, and what do we require of them? They ought to help keep in place the soil immediately adjoining the walks, to delineate their outlines, and to form a separating line between the walks and beds. To attain this result, for a long time past the dwarf Box, known as edging Box, has been used. It is a very small evergreen shrub, and, thanks to the cutting, which it stands well, easy to keep in place. After some years it must be renewed, for becoming too high, in spite of severe trimmings, it surpasses the limits assigned to it. This renewing is generally done in the autumn, but is better done in spring when growth begins. Box is replanted by placing it deeper in the soil and less closely together. It has always been urged against Box that it harbours many insects, and more particularly slugs and snails, which devour the young plants cultivated near it. In the hope of preserving kitchen garden plants from their depredations, tiles placed upright in the soil, and buried for two-thirds of their height, are often used to border the paths. Very often in small gardens tiles are used, of which the end intended for placing in the ground is rectangular, while the top forms an undulating or broken line. They are seldom graceful, and the more or less pronounced brick-red tint harmonises badly with the rest of the garden. If Box and the different kinds of tile are eliminated from the material for the composition of borderings, we must seek among the useful plants themselves, which, from their reduced size, their foliage, and their manner of growth, may be used with good prospect of success for the purpose.

THE CRIVE is a plant to be recommended for an edging. It is a small perennial, which does not get out of place during development. If, after the leaves have been cut off close to the ground before winter, it is covered with a little soil it may remain in place for three or four years. If it spreads a

little too much, its lateral development can be limited by a cut made with the spade on either side of the border. It is generally replanted in April by dividing the tufts, from which for preference the outside parts are taken, as being younger and more vigorous. In the spring this pretty little plant is covered with bunches of flowers scarcely higher than the leaves; their great number form for a time a pretty ribbon of violet-red.

CURLED PARSLEYS, especially the dwarf green variety, are very well adapted to the purpose. Sown rather thinly, and frequently renewed by the removal of the old leaves, their foliage remains fresh and green; the crinkled leaves render them very ornamental. As Parsley runs to seed the year following its sowing, it is necessary, in order to have well-furnished edgings of it, to make new sowings every year.

SMALL BURNET is a hardy plant, growing in almost any soil, of small size, with light foliage easily renewed within a short time after having been cut, and thus the plants remain furnished. It is sown either in autumn or in spring, and since it is perennial will last for several years; but as in time some gaps are formed in the border, it is better to renew it every two years.

DE GAILLON STRAWBERRY OR ALPINE STRAWBERRY without runners is very suitable for a bordering. Thanks to its tufted and erect habit, as well as to the complete absence of runners, this plant takes up but little room. It may be multiplied by sowing, though with this method of propagation all the specimens are not always of regular growth. This fault may be remedied either by sowing apart, and selecting plants from the seedlings for a year at least before putting them in their permanent situation, or, which is much simpler, by dividing early in the spring the old roots and replanting them in line.

SORREL, though it is not ornamental, is frequently grown as a bordering. It does not run to seed, or at any rate it constantly sends forth shoots, if care be taken only to plant male roots. Borderings can thus be obtained of considerable duration. They are renewed every three or four years by dividing the tufts, which are afterwards replanted, advantage being taken of this replanting to eliminate the female roots, if by chance there were any in the preceding planting.

COMMON THYME is also frequently employed for edgings. It succeeds where many other plants would suffer from the heat, for it likes, and does best, in warm situations. It is propagated by sowing, where it is to flower, in April. If, however, it is requisite to grow it on a sloping surface, where watering is difficult, it would be better to sow it in the nursery, and when the plants are sufficiently developed to bear removal without danger to transplant them in the following June or July. Since Thyme grows quickly, it will be as well to trim it back when growth begins the next year in order that it may not spread beyond the limits assigned to it; clipping the ends of the young shoots while green will, while preventing their elongation, give a denser growth, more suited to the object in view. Although other kitchen garden plants can be used for the purpose, we will here end our choice, for we do not recommend the different varieties of wild Chicory, which in the interior of the beds, as borders for the working paths, can trail their long leaves without harm to the general effect.

V. ENFER, in *La Revue Horticole*.

NOTES OF THE WEEK.

FORTHCOMING EVENTS

October 4.—Royal Horticultural Society's Fruit Show in New Hall (three days).

October 5.—National Chrysanthemum Society's Show at Crystal Palace (two days).

October 12.—Royal Botanic Society's Show.

October 18.—Royal Horticultural Society, Meeting of Committees, 12 noon.

October 25.—Croydon Chrysanthemum Society's Show (two days).

Great autumn show of British-grown fruit.—On Tuesday, Wednesday, and Thursday, October 4, 5, and 6, the Royal Horticultural Society's eleventh annual show of British-grown autumn fruits will be held in the new Hall, to which the public will be admitted at one o'clock on the first day and at ten o'clock on the other two days. The show will remain open till 10 p.m. on the first two days, and will close at 6 p.m. on the last day of the exhibition. Copies of the schedule and entry forms may be obtained on application to the secretary of the Royal Horticultural Society, Vincent Square, Westminster.

Dryas octopetala.—An unfortunate mistake, through a mixing up of blocks, occurred in *THE GARDEN* of last week, page 195. An illustration of *Dryas octopetala* was inserted for one of *Anemone alpina*. Happily the mistake is obvious, as several correspondents have kindly pointed out.

Romneya trichocalyx.—This new species of the genus *Romneya*, which was introduced into England a few years ago, has recently flowered at Kew for the first time. It is allied to *R. Coulteri*, but it is distinguished from it by its woolly calyx (a peculiarity indicated by the specific name) by its more slender, spreading, and leafy stem, and by its leaves, which are from three to five lobed. The plant grows vigorously; the specimens in flower at Kew were 4 feet to 5 feet high. The colour of these flowers is white.

IN MEMORIAM.

SAMUEL REYNOLDS HOLE, DEAN OF ROCHESTER.

LET all the Roses that remain
After the August wind and rain
Shed teardrops and be sad awhile.
For he is dead who loved them so,
From Damask Rose to Jacquemont,
And every Sweet Briar bud ablow
In the four quarters of the isle.

Bright-blossomed Marie Henriette,
Are not your leaves and flowers wet,
Although last night there was no rain
The grass upon my lawn is dry,
But drops are on the Verdier nigh;
And Seven Sisters, near to die,
Have yet got strength enough to sigh,
"Good-bye—until we meet again."

The Roses that you loved are bound
Also to All-Men's-Meeting-Ground,
The earth's brown bosom, warm and kind.
Preacher of gentle works and ways,
Lie down to slumber, full of days
And honours, while the Roses raise
Triumphal arches in your praise,
And breathe your name upon the wind.

NORA CRESSON, in *Country Life*.

A fine Apple.—Connoisseurs in cooking Apples will do well to plant a few bushes of Thomas Rivers. This variety, though it obtained a first-class certificate of the Royal Horticultural Society, seems to have escaped general recognition and does not appear in all catalogues. The tree, in the form of bushes on broad-leaved Paradise, is a magnificent grower with me, robust, short-jointed, with dark leathery foliage, and seems a sure and heavy cropper. The fruit swells to a large size, even when left in bunches of three or four. The form is somewhat egg-shaped, and the colour, in full exposure, of an attractive yellow, more or less streaked and flushed with red. This Apple is remarkable for its weight and density of flesh, but still more for its quite extraordinary flavour, which is that of a rich Apple, with the aroma of a fine Pear thrown in. I know nothing at all like it. We are using it at present (September 19), and it keeps well up to Christmas.—G. H. ENGLEHEART.

Mr. J. F. Hudson, M.A., B.Sc., has been appointed Principal of the Huddersfield Technical College. Mr. Hudson (for some years honorary secretary of the National Dahlia Society) was educated at St. Paul's School, West Kensington, and was Open Scholar Exhibitioner and Prizeman at Jesus College, Oxford. He obtained First-class Honours in the Mathematical Moderations of 1893, and in the finals of 1895, and honours in Physics, 1896, when he took his degree of M.A.

He was Assistant Lecturer in Mathematics at Jesus College and Demonstrator of Physics in the Clarendon Laboratory, Oxford, from 1897 to 1900. Mr. Hudson, who is thirty-two years of age, was recently head of the Department in Mathematics in Hartley University College, Southampton. The salary at Huddersfield is £500, with the prospect of being eventually appointed Director of Education for the borough. Mr. J. F. Hudson is the son of Mr. James Hudson, head gardener to Mr. Leopold de Rothschild, Guernersbury, and a member of the council of the Royal Horticultural Society.

Mr. J. H. Goodacre.—We are glad to hear that Mr. Goodacre, head gardener to the Earl of Harrington at Elvaston Castle, and widely known as an expert fruit grower, is recovering from his recent severe illness. Mr. Goodacre was taken ill at the Shrewsbury show.

Some hardy flowers worth growing.—The plants mentioned below will interest those who love hardy flowers and are worth growing: *Lysimachia Fortunei*, like *L. clethroides*, but better. *Vitis* (*Spinovitis*) *dauriana*.—To the lovers of Vines this is an interesting addition. It is a strong climber, with handsome foliage, the stems prickly. *Polygonum equisetum* (*australe*).—For a warm rock garden this is a lovely thing. It is hardy here and stands the winter, does not run unduly, and has long streamers of white flowers. *Polygonum baldschuanicum*.—Many of my friends tell me they cannot grow this, and decry it accordingly. Here it completely envelopes a tall Pear tree so as to hide the natural foliage, and is now in its second blooming this year, a pyramid of pink sprays 18 feet in height. *Rhodochiton volubile*.—I pointed out the beauty of this charming creeper in a previous note, but a letter from one of your best known contributors complained of its dulness of colour. If it is grown on tall Hazel branches, shaded slightly from the midday sun, and so placed that the western sun shines through it it is indescribably lovely; a wall spoils it. *Campanula mirabilis*.—Five years since I obtained seed and raised a large number of seedlings. None flowered till the third year; the bulk in the fourth year. Even yet a few will wait until the fifth year. It is very hardy; very beautiful, and seeds freely, self-sown seedlings coming up in every direction. *Gentiana macrophylla*.—I have a very fine variety of this from Italy. It is exactly like the pale yellow variety in growth, but the flowers are a beautiful blue. The past season should prove a perfect seed year, and we may look forward to success in establishing new varieties.—P. H. MILES, *The Old Parsonage, Gresford*.

Glasgow Parks Department.—Some interesting figures appear in the accounts of the Parks Department of the City of Glasgow for the past year, and a few points may be worth recording in *THE GARDEN* as showing the condition of matters in a city which has shown such an enterprising spirit in providing open spaces for its citizens. The revenue for the year was £82,812 17s. 1d., while the total expenditure, including sinking funds, amounted to £79,498 0s. 5d. The surplus was thus £3,314 16s. 8d. Every penny per £ of rental produces £19,630, fully £700 more than in the previous year. The estimated revenue for this year is £83,400, while the estimated expenditure is £82,092. The assets of the department are valued at £1,123,063 4s. 11d., and the liabilities (including £148,498 of sinking fund) amount to £918,518 8s. 6d. The position is thus a favourable one, and reflects much credit upon those responsible for the working of the various departments.

Cactus Dahlia Columbia.—Of the fancy striped type of Cactus Dahlias this variety still holds its own very well indeed. At the Alexandra Palace show on the 7th inst., Messrs. J. Cheal and Sons, Crawley, showed a fine lot of blooms in a spray of six, and each bloom was of a high order of merit. A good description of its colour is as follows: Rich bright vermilion ground, the centre and top of each floret being pure white. The form is exquisite, the florets being long and incurving. As a garden plant this variety has much to commend it, being free flowering and consistent, reaching a height of rather less than 4 feet.—D. B. C.

Montbretia George Davison.—Of all the pure yellow forms of *Montbretia* George Davison is quite the best. The growth is vigorous, the blossoms freely produced, and the colour two shades of yellow—orange and a paler tint in the centre.—E. M.

Montbretia Germania.—For brightening the border in September this *Montbretia* is much better than *M. crocosmæiflora*, not only in freedom of flower but in brilliancy of colouring. This is orange-red, with an especially bright eye. No *Montbretia* that I know will give such a mass of colour as this.—E. M.

Anemone japonica Queen Charlotte.—By far the best of pink flowering varieties is this. Not only does it give its flowers in greater abundance, but they are so decided in colour, a delicate soft shade of pink, darker on the outer petals. So stiff and branching are the flower-stems that they require no support whatever.—E. M.

Clematis davidiana.—Among September flowering plants in the open border none is more showy and attractive than this herbaceous *Clematis*. In the colour of the flower there is something about the delicacy of the blue tint that is unrivalled. Under good culture the plant reaches 3 feet in height, and is easily supported. No question has ever arisen in my mind about its hardiness; I find it perfectly so, and recommend it wherever flowers of this colour are required.—E. MOLYNEUX, *Bishop's Waltham*.

A fine Grape room.—A dry, well-ventilated room in which to store cut bunches of Grapes in the winter after vineries have been cleared of their crops is essential in all good gardens. Probably there is no more completely fitted room anywhere than the one recently erected at the Royal Gardens, Frogmore, and which has a capacity to store no less than 1,000 bunches. The room forms a part of a long range of lean-to stores and sheds. The walls are boarded, and to these, back and ends, are fitted, one above the other, five stout rails; each rail, which has a slanting or oblique face, is bored 3 inches deep at intervals to receive the bases of the bottles. There are also eight sets of crossbars projecting from the back. Each set is of five bars, and each bar is bored to take eleven bottles on each of its oblique faces, in all 110 bottles. Late Grapes, especially Lady Downe's Seedling, have been largely planted in the new vineries.—A. D.

The Persimmon.—The other day, in Canon Ellacombe's most interesting garden at Bitton, I saw *Diospyros Kaki* against a wall with a fine crop of about forty fruits. Canon Ellacombe informed me that it fruited with him almost every year. It has occasionally fruited in the open elsewhere in the British Isles, and in *THE GARDEN*, page 90, Vol. LIX., I recorded its having fruited near Teignmouth, South Devon, while on page 40, in the same volume, Mr. T. Shaw mentions it as having fruited at Caerleon, Killiney, Ireland. The fruit borne in South Devon, which I tasted and found palatable, was dull red in colour and about 3 inches in diameter.—S. W. F.

Lilium speciosum Melpomene.—This Lily, referred to on page 166, is, as there stated, one of the most handsome of the varieties of *L. speciosum*, and one of the richest coloured. It is imported every year in large numbers from Japan, and finds a ready sale in this country. Formerly the Lily bulbs disposed of at the London auction rooms under the name of *L. speciosum rubrum* consisted principally of the true *rubrum* and *Melpomene* mixed, but within the last few years those of *Melpomene* have been kept distinct by the Japanese themselves and catalogued as such. Still, even now there is a certain amount of mixture among them, and of course a good deal of individual variation. Anyone accustomed to handling in quantity the bulbs of these Lilies can almost unfailingly select those of *Melpomene* from *rubrum*, as in *Melpomene* they are darker in colour and show a great tendency to divide into several crowns, whereas in *rubrum* they are more compactly built. Apart from the rich colour of its blossoms *Melpomene* is distinguished during growth by its dark-coloured stems and leaf stalks, while the leaves are deeper in tint and

rounder than those of any other variety. Large bulbs of this, too, will often push up a number of stems. It is very interesting to note the great difference between the bulbs of the several varieties of *L. speciosum*, thus those of the two varieties in which the flowers are white tinged on the exterior with green, viz., *album novum* and *Kratzeri*, are of a yellowish hue, whereas in *album* (of the Dutch), suffused chocolate outside and white within, they are of a deep mahogany tint.—H. P.

Campanula pulloides.—I send you a small photograph of the very scarce *C. pulloides*, a supposed hybrid between *C. pulla* and *C. turbinata*. It is a most showy, free flowerer at the end of June and during July. The flowers combine the substance of *C. turbinata* with the intense glistening purple-blue of *C. pulla*, which species it resembles in general habit of growth; the height is about 5 inches. The stems and foliage are sparsely covered with long stiff hairs. In a mixture of half fresh loam, a quarter grit or clean river sand, and a quarter leaf-soil the plant grows splendidly. It must have a sheltered but a north or west exposure, as, although the fleshy and almost globular flowers are substantial enough,

THE RARE CAMPANULA PULLOIDES.

(A supposed hybrid between *C. pulla* and *C. turbinata*.)

along with many others of our brightest flowering things, they resent even the shortest periods of bright sunshine.—J. Wood, *Hardy Plant Club, Kirkstall*.

Argemone grandiflora.—For a long time this handsome Poppy-wort has been producing a succession of its large white flowers. Although it is stated to be a perennial in its native country (Mexico), here it has to be treated as a half-hardy annual, sown in heat in the beginning of March, and planted out when large enough early in the month of May. Like many of the plants of this family it dislikes being transplanted, and great care should be exercised in planting it out, the least twist given to the seedling being fatal. A rapid grower, it makes a bushy plant about 4 feet high, with branching purplish stems covered with a glaucous hue, the pinnatifid leaves are from 6 inches to 9 inches long, with light midrib and veins. They are also prickly underneath, although this species is the least prickly of all the *Argemones*. The large white flowers, like those of a *Romneya*, are fully 4 inches in diameter, and have a bunch of yellow stamens in the centre. With a

number in flower at a time the effect is charming, and considering that it commences to flower at the end of July and keeps on till cut down by frost, it is a useful plant for borders. Unlike most of the other members of this family its seeds are not produced freely, and it may be due to this fact that it has not become common, although introduced into this country in the year 1827. A similar plant with even larger flowers is *A. platyceras* from the open plains and banks of streams in California and Texas. It differs in having a bunch of red stamens in the centre of the white flower and in being much more prickly all over, especially the fruits, which are closely packed with spines. Quite as free flowering as *A. grandiflora* and still in full flower, it promises to ripen plenty of seeds. There is said to be a rose-coloured or purplish form of this to be found in southern Texas, and altogether it is a more variable species than the former. A sunny position in light sandy loam is suitable for both plants.—W. I.

Window-box prizes at Dalkeith.—The improvement effected in many towns by giving prizes for the best window-boxes has been generally recognised, but there are few towns of its size so well situated as Dalkeith is at present through the generosity of Provost Chisholm, who this year again gave the handsome sum of £35 for prizes for window-boxes within the burgh. The competition has created much interest, not only among the competitors, but also among their neighbours and others. Three sections have been formed, and for each of these several first, second, and third prizes are awarded. The judges have announced their decisions, which appear to give general satisfaction. A number of the boxes show both tasteful arrangement and good cultivation.

Rosemary as a wall climber.—Where a dense evergreen growth and something unusual are appreciated as a wall covering Rosemary is worthy of consideration. Planted at the foot of a west wall it quickly grows, flowers abundantly, and needs but little attention in the way of training or pruning. The chief point is to lay in the leading growths as many as are required to cover the desired space, and then spur in the foreright shoots. After that is achieved allow these growths to produce their blossoms at will, and in the early autumn cut back superfluous shoots.—E. M.

Montbretia Chloris.—This variety of *Montbretia* is by no means new, but it is rare enough to warrant a note as to its usefulness at the present season. It closely resembles George Davison, a splendid form of recent introduction, but the flowers do not expand so widely, and they can only be described as broad bell-shaped. In colour they are a deep saffron-yellow, almost self-coloured, and the spikes are ten to twelve branched, fully 2 feet high, and they flower very freely, a display being maintained for six weeks. It is an unusually vigorous *Montbretia* of a good clear colour, and a distinct advance on the rank and file of *Montbretias* now so popular. One cannot grow the plant too well, and in the North it may be necessary to lift the bulbs to ripen, but not to dry, so that the stout, green shoots become withered, for these produce the strongest flower-spikes. It has unusually broad leafage and flowering growths.—G. B. M.

Plantago maxima.—It is not often one can appreciate beauty and garden value in a Plantain, yet *P. maxima* certainly has both, and that in appreciable quantity. Its leaves are broadly elliptical and boat-shaped, and form a lax rosette. A series of spikes 2 feet long are produced throughout summer, the flowering portion of which is 6 inches long, somewhat resembling *Cimicifuga* or *Sanguisorba*. The spikes are an inch in thickness, and are mainly composed of bristling white anthers, and arranged bottle-brush fashion. The plant is never likely to become popular, yet everyone who sees the flowers admires them till they know it is a Plantain. To my mind, a clump of half a dozen plants in flower is a pretty sight, and one would not need apologise for its presence in the flower border if its name could be kept in the back-ground. It is an extremely handsome Plantain, however, and many will, doubtless, admire it.—G. B. M.

SOME SUMMER AND AUTUMN - FLOWERING BULBS.

IN the word "bulb" there is a latent magic, though it is one of the ugliest of the many ugly ones in the English language, and when the summer glory of the garden begins to wane, and there comes an autumnal feeling, however slight or transient, into the air, the soul of the true gardener at once responds in obedience to a familiar but overpowering influence, and flies eagerly forward to the future delights of the spring bulbs.

How delightful they are, indeed, and how splendid our display is going to be this next spring! What improvements we have in our mind, what delicate combinations of colour, what nice little nooks and corners there are to be filled with *Scillas* and *Chionodoxas* and *Daffodils*! And then that first bulb catalogue of the autumn; what a thrill of delight we experience on finding it lying on the table among our letters. It may be from an untried, perhaps unknown, firm, but we hastily tear off the cover, study the long list of good things and their prices, wildly mark nearly every one of them, and then—we carefully put it away for future reference, and do the same to the next catalogue we receive. The cry is "Still they come," but in the end we settle down to business and write our order, and even send it off, probably to some familiar firm that we have dealt with before, and await the result.

We know that we have ordered many bulbs that we don't want or can't hope to grow, and have forgotten several most desirable ones; but no matter. The question is, When shall we get them! They ought to be planted soon. Are we not a bit late, after all? Will they do as we particularly asked them, and send the *Narcissi* at once, or shall we have to take our chance with the rest of the orders, and find ourselves behindhand, as usual? All this is so familiar to myself, such a part of my year's gardening, that I have ceased to struggle against fate, and do the best I can when the long-expected and beautifully-packed parcel of bulbs does eventually arrive.

Still worse is it when we are ordering autumn-flowering *Crocuses*, *Sternbergias*, *Colchicums*, &c. The suspense is fearful, and the "agonised" post-cards to the much-abused firm of nurserymen, urging them to the immediate despatch of the goods, are sent off two or three times a week. Of course, we are aware that such bulbs ought to be safely planted in August, as, indeed, ought all the spring-flowering *Narcissi*, but we do not always realise how time is slipping away, and how late we are in making out our order for them. Anyhow, we won't forget another time, and, perhaps, with favourable weather we shan't do so badly after all this autumn with *Crocus speciosus* and the *Sternbergias*; besides, if you remember, the *Daffodils* we put in last November flowered splendidly in the spring. And so we go on from year to year—at least, some of us do, myself among the number, and yet we are quite happy and love our bulbs more and more, and contrive to have a charming display in their flowering time. But I think we are all just a bit too much devoted to the spring bulbs only, not paying sufficient attention to those that bloom in the summer and autumn. It is in reference to these, many of them gloriously beautiful, easy to grow, and by no means expensive, that I venture to make the following remarks. I propose to confine myself to the bulbs or bulbous plants of the great natural

order *Liliaceæ*, and take them alphabetically. The list contains most of those that can be recommended for their beauty and comparatively easy culture. Some of them, it may be said, are not bulbs in the true botanical sense of the word; but we gardeners are not too particular, and may safely include them all under that denomination.

ALLIUM.—Many of the *Alliums*, in spite of the "soupçon" of garlic in their handsome flower-heads, should certainly be grown more commonly, either in the borders or in the wild garden, for they are remarkably easy of culture and very effective. Those that flower in the summer are *A. acuminatum*, deep rose, and its variety *murrayanum*, rosy purple; the distinct and handsome *cœruleum*; *macnabianum*, of an unusual magenta colour; the old familiar and delightful *Moly*; *narcissiflorum*, a graceful species with fine rosy flowers; the well-known *neapolitanum*; *nigrum*, with green-veined whitish or violet umbels; *ostrowskianum*, rosy purple; *Schuberti*, a comparatively new species, somewhat tender, with very striking rosy or lilac flowers having red stamens and white anthers; and the white-flowered sub-*hirsutum*. Well-drained soil, with a good mulch of leaf-mould or old manure in summer, and plenty of water in dry hot weather, will enable us to grow many beautiful flowers of the *Allium* in sunny parts of the garden, and we certainly have a pleasing variety of colour at our disposal. *Alliums* seed freely, and the young seedlings are sometimes rather a nuisance, but they are easily got rid of when small. I remember a certain *mauvais quart d'heure* on my knees, extracting tiny plants of *ostrowskianum* from my pet clump of *Nierembergia rivularis*, and I now keep a better look-out for the insidious little strangers.

BLOOMERIA.—Both species now in cultivation, *B. aurea* (*Allium croceum*) and *B. Clevelandi*, are very little grown though they are handsome and effective, with bright yellow flowers. They require a warm sunny corner, a good light sandy loam, with a little judicious coddling in winter.

BREVOORTIA.—The extremely pretty *B. Ida Maia* (*Brodiea coccinea*), or "Californian Fire Cracker," is sadly neglected. A clump in a warm border, in rich light soil, with the tall delicate flower-stems artistically staked or otherwise supported, is truly delightful. The corms may be safely left in the ground, if slightly protected with ashes or peaty soil in winter.

Yalding, Kent.

(To be continued.)

THE ROSE GARDEN.

ROSE SOUVENIR D'HELENE.

ALTHOUGH as a novelty it appears to be wanting in form this Rose must not be forgotten. As the collection of Hybrid Teas is now so large caution is needed by raisers before they swell the already large group with second-rate sorts. The flower is too full, as exhibitors would say, consequently a special season would probably suit it best. In opening the colour is something in the way of *Souvenir du President Carnot*, but as the flowers unfold more of the salmon tint is perceptible. It apparently belongs to the *Caroline Testout* race, and for this one must be thankful, for this means freedom of growth. The weak point about the variety is the folding over of the centre petals, which to some individuals is a detraction in *Caroline Testout*. Were it not for this *Souvenir d'Helene* would be a beautiful Rose, and it is

very fragrant. I have not yet proved the Rose on cut-backs; perhaps it may unfold better from such plants. P.

ROSE MORNING GLOW (TEA-SCENTED).

THIS is a remarkably good Rose for the garden, and I believe it will be in much request. The colour is so attractive—a rich and glowing rosy crimson, suffused with orange and fawn. In some respects it resembles *Mme. Lambard*, but there is a more constant effect of colour as compared with the varied tints which are seen in flowers on plants of the old favourite named. *Morning Glow* is very vigorous in constitution, equalling in this respect *Mme. Lambard*, *Marie van Houtte*, and other Roses of that type. It cannot fail to please all who cultivate Roses, for there is a subtle charm about its colour which appeals to those who place colour and vigorous growth before form. As a pot Rose *Morning Glow* is a great success. P.

SEASONABLE NOTES.

ROSE PEACE.

AS soon as I was aware that this Rose was a sport of *G. Nabonnand* I could see that we had obtained a really good thing. It has all the points of the latter incomparable garden Rose, and only differs from it in colour. This is a pale lemon-yellow, changing to delicate lemon-white. The two sorts mingled, or placed in juxtaposition, would have a nice effect.

ROSE SULPHUREA.

This beautiful bedding Rose is proving one of the best varieties that have been introduced for several years. Its chief charm is the way in which the individual blossoms display themselves, each flower being quite erect and well away from its neighbour, so much so that it is not at all uncommon to see one truss of four and five blossoms having a spread of 15 inches to 18 inches. The colour effect of *Sulphurea* in the distance is white, but on close inspection the pale sulphur-yellow is seen especially in the charmingly-formed buds. It is to be hoped Messrs. William Paul and Sons, the raisers of this Rose, will give us more of this type in other colours. Their new variety *Warrior*, which was exhibited in the early summer at *Regent's Park*, struck me as being another good thing. Its colour is much deeper than *Papa Gontier*, and the growth even better than that popular sort. It is brilliant bedding Roses we want, then we shall be quite independent of other bedding things. It is freely admitted that the bedding Tea and Hybrid Tea Roses for continued effectiveness through the summer and autumn months are among the best subjects for this purpose. By careful preparation of the beds, ensuring the roots a good depth of soil, growth goes on unchecked, consequently there is nothing but vigour and free blossoming from this race.

ROSE RAINBOW (TEA-SCENTED).

All who can appreciate striped Roses should have *Rainbow*. It has all the good attributes of its parent, and only differs in that its flowers are pale pink, heavily flaked with the reddish crimson of *Papa Gontier*. The buds just before they unfold are very pretty, and the variety is certainly worth growing, not only as a novelty but also for its decorative value.

ROSES COMMANDANT FELIX FAURE AND BOB DAVIDSON.

These are two grand high-coloured Roses, which we welcome most cordially. The former is a brilliant vermilion, richly shaded with the blackish maroon of *Prince Camille de Rohan*. The flowers are large, inclined to be globular, but quite expansive enough to unfold well. It is a splendid grower, and must take a prominent place in our gardens. The growth being somewhat spreading, this Rose should make an excellent standard.

Bob Davidson is quite a different Rose, its pointed petals and rather tight flower being distinct characteristics. The colour is of the intense shade seen in *Victor Hugo* and *Duchess of Bedford*; it is apparently a better grower, being more branching

than either. I regard these two brilliant Roses as first-rate additions to our Hybrid Perpetuals, and it would be a commendable work if hybridisers would seek to infuse the free flowering habit of the Hybrid Teas into some of our brilliant and fragrant Hybrid Perpetuals.

ROSE EARL OF PEMBROKE.

This fine crimson Rose is always good in autumn. It is one of the late Henry Bennett's seedlings, and a good one it is. Possessing much of the habit of Marquise de Castellane, from which the variety was raised, the pollen parent, Ferdinand de Lesseps, has apparently imparted the crimson tint and less rigid growth than is present in the seed parent. Coming from two such fine Roses it is quite natural Earl of Pembroke should be very fragrant. This Rose always reminds me of a variety raised by Thomas Laxton and named Charles Darwin. There is a perceptible brownish hue about both. If neither of these Roses is in the collection I would advise my readers to procure them.

ROSE MME. VERMOREL.

This splendid Tea Rose has been very fine lately, in fact it is always good. It is one of those large double Teas that will expand well, no matter what the weather may be. Its only fault is that the blossoms droop because they are so weighty; but I do not think that any detriment, because such a fine bloom will well repay the trouble of tying the growths to a small stick. It reminds me somewhat of Jean Ducher, but there is more of a rosy hue on the outer petals. The predominant colour, however, is coppery yellow. It is a fine vigorous grower, and should succeed well at the foot of a wall, as a bush in the open garden, or as a standard. For forcing, too, it would be an excellent addition to the good winter-blooming Roses.

ROSE ULRICH BRUNNER AND OTHER HYBRID PERPETUALS FOR JANUARY BLOOMING.

Established plants in pots of the above grand winter Rose should now be dried off preparatory to pruning them in October. Although Liberty is certainly the most brilliant of our winter Roses, the bold flowers of Ulrich Brunner have a special value so early in the year. Plants that were potted from the open ground last autumn would be the best for this work. They would not now need repotting, but their crocks should be examined and a top-dressing with some good compost afforded. This Rose should be worked on the Manetti stock for this early forcing; in fact, I think it is best for all Hybrid Perpetuals in pots, although such plants are not so lasting as those on the Briar. If some bone-meal were put into the compost at the time of potting, the plants would require no stimulants until the buds are about the size of Peas. Then a sprinkling of Clay's or other good fertiliser will be beneficial, in addition to liquid manure made by steeping some cow manure and soot in a tank or cask. By a system of resting the plants every other year, then hard pruning, fine long growths can be secured. But if such growths are cut away with the flowers it does not pay to grow the plants a second year, seeing that bush maiden plants are now so cheap. Of course to provide for this discarding of old plants a fresh batch must be potted up each autumn.

ROSE PERLE VON GODESBERG.

I think rosarians have been rather premature in condemning this Rose. It is true the blossoms do not show the golden yellow which we may have expected, but there are signs that this colour is lurking in the variety which careful selecting may bring out. Undoubtedly the introducer distributed the Rose before it was "fixed." In any case the variety appears more vigorous than Kaiserin Augusta Victoria, from which it sported, and even

if we do not obtain a "yellow Kaiserin," as we expected, we have at least a grand variety with a constitution much superior to the Kaiserin. P.

TREES AND SHRUBS.

CATALPA BIGNONIODES.

I AM sending you a photograph of *Catalpa bignonioides* (the Indian Bean Tree). It is perfectly hardy here, and flowers profusely every year, producing seed vessels from 6 inches to 10 inches long. It flowers in August, a season when few trees or shrubs are in blossom. I believe this tree is better known as *C. syriacaefolia*. The photograph was taken on August 16.

The Gardens, Fairlawn, Tonbridge. F. C.

AUTUMN PLANTING.

THE season for planting trees and shrubs is now close at hand, and no time should be lost in preparing

will save much labour and expense in the future. Preparation of the ground should have already been done, but if not it should be taken in hand at once. Where borders or shrubberies are to be planted, the ground should be thoroughly trenched, the depth depending on the nature of the subsoil and the amount of drainage. Light ground with a gravelly subsoil can be broken much deeper than where the subsoil is stiff and clayey, as in the former the roots must penetrate deeply to find sufficient moisture in dry weather, but in the latter the water is liable to collect in the lower part of the trenched portion, especially if the surrounding ground is unbroken. Where isolated specimens are to be planted, holes 6 feet in diameter should be dug out and left open until required. It is better to make the holes too large than too small, as the larger the holes the longer the roots will be before they get into unbroken ground, and the faster will be the growth of the trees for the first few years. The shape of the holes is immaterial, the chief thing is to make them large enough. Manure will only be required with such as Hollies, Yews, Box, &c., though a good mulching of all fresh-planted trees and shrubs is beneficial the first year.

CATALPA BIGNONIODES AT FAIRLAWN, TONBRIDGE.

for it, as during the next six or eight weeks the conditions of soil and climate are the most favourable for the production of new roots by freshly-moved plants. Before the actual planting takes place, however, there is much to be done in the way of arranging where things are to be planted, preparing the ground, digging holes, &c. There are also stakes to be provided for those trees that may require them, together with string or wire for ties, and pieces of sacking or old hose-pipe to prevent the stakes from rubbing the bark of the trees. Some of these things may seem minor matters, but it is the attention given to details that ensures success in planting as in every other garden operation.

In arranging where the various trees and shrubs to be planted are to go, attention must be paid to the ultimate size they will attain, as it is poor policy to put a large-growing tree like a Lime, Elm, Douglas Fir, or Spruce in a place where a flowering Cherry, *Pyrus floribunda*, or a Holly would be large enough. A little forethought about what to plant, and where to plant it,

Those trees that require it should be staked as soon as planted, using three stakes to each tree. These should be driven well into the ground 4 feet to 6 feet from the base of the tree at equal distances all round, and be brought together at the stem and tied there, using a piece of sacking or some such material to prevent the bark being rubbed. Large bushy evergreens can be made secure by using three lengths of string or wire fastened to pegs driven into the ground instead of staking them. Wire is better than string for this purpose, as it does not alter in length during changes of weather in the same way that the latter does. When trees or shrubs are bought in they should be looked over before being planted, and any broken or bruised roots cut off with a sharp knife, cutting upwards from the lower side of the root, so that a wedge-shaped end is left to protect the cut portion from water soaking in from the surface of the soil. If the roots are dry they should be soaked an hour or two before planting, and protected from wind and sun by mats. In light soils trees and shrubs should be planted slightly deeper than they were before,

but in heavy ground they do better if raised a little, especially if the ground is inclined to be wet. Before planting the bottom of the hole should be made moderately firm, the plant set in, and the roots laid out separately all round, covering them with the best and finest of the soil, which should also be worked into any hollow places at the base of the stem. When the roots are covered fill in the hole and make the soil firm. If the mass of soil and roots is rather hard, the outside should be loosened with a pointed stick.

To sum up, there is much to be done besides the actual planting, and if everything is arranged and provided beforehand it will mean time and labour saved, besides giving the plants every chance of recovering after their removal.

Bayshot, Surrey.

J. CLARK.

THE CLEMATISES.

COCCINEA HYBRIDS.

(Continued from page 154.)

CLEMATIS BERGERONI is a pink-flowered plant, very similar to some forms of *C. intermedia* in habit. It blossoms freely during July and August.

C. calycina cannot be said to be everyone's plant, for it flowers in midwinter, and is rarely seen in good condition. It has evergreen, very finely divided leaves, and dirty, greenish white blossoms 2 inches to 3 inches across. It is found in the Balearic Islands, and should have a place on a warm wall.

C. campaniflora.—This is one of the daintiest of all, and one that should be grown more largely than at present. It attains a height of quite 15 feet, and quickly makes a fine mass. It was introduced from Portugal in 1810, and is distinguished by means of its slender stems, small simple, bi- or tri-parted leaves, and tiny campanulate blossoms barely 1 inch across. The colour may be either white or pale blue or mauve, and it is at its best in July and August.

C. cornuta is a strong-growing, large-leaved Himalayan plant. The flowers are small, tubular, and pale yellow. It is not a very ornamental species.

C. crispa differs from most by the shape of its blossoms. It comes from the Eastern United States, grows 5 feet to 6 feet high and bears somewhat fleshy cylindrical flowers, which are from 1 inch to 1½ inches long, the ends of the sepals being reflexed. The blossoming period is late summer, and the colour of the flowers pale lilac.

C. Flammula is a well-known, strong-growing European plant, bearing during late summer large panicles of fragrant white flowers. It is an excellent subject for a semi-wild position.

C. grata forms a strong-growing plant, with large, bright green leaves and big panicles of small white flowers borne in August. It is found in the Himalaya.

C. heracleifolia and its varieties make a distinct group of sub-shrubs. They come from China, and vary in height from 1 foot to 4 feet. The leaves are ternate and large, the flowers small, tubular, and blue, and borne during late summer in axillary and terminal clusters. The best known varieties are *dauidiana*, *Lavallei*, and *Stans*. *C. h. davidiana* makes a good subject for a bed.

C. montana.—This is a popular spring-flowering species from the Himalaya. It was introduced in 1831, and is a very strong grower, rising to a height of 18 feet or more. It is an excellent plant for walls, pergolas, and similar places, and flowers well in April, the blossoms being pure white and forming long elegant sprays, single blooms being borne from most of

the leaf axils. In the warmer parts of the country it does well in the open.

C. orientalis.—In 1731 this species was introduced from the Orient. It is very distinct, making a graceful climber 7 feet to 9 feet high, with small pinnate leaves. The flowers are pale yellow, and are in evidence from July to September. A variety called *tangutica* has been introduced within the last few years. It is a great improvement on the type, having much larger deep yellow blossoms with long acuminate sepals.

C. paniculata.—It is only in the warmer parts of the country that this Japanese species does really well, for although it makes a lot of rank growth about London it rarely blossoms well. In Cornwall I saw a very fine specimen in full flower last September, the whole plant being smothered with panicles of pure white flowers, each of which was from 1 inch to 1½ inches across. When planted it should be given a warm wall, except in the south-west counties.

C. virginiana is a native of the United States. In many respects it is similar to *C. Vitalba*, and can be used in half-wild places.

C. Vitalba is well known as a hedgerow plant; it is, however, worth growing in the wild garden or back of a shrubbery, where it can have lots of room to ramble.

C. intermedia is of sub-shrubby habit and bears numerous purple flowers in July. There are forms with pink blossoms.

The herbaceous group contains very few that call for special notice. *C. coccinea*, a native of Texas, is very distinct and showy, the flowers being tubular and scarlet. It should be grown at the foot of a south or west wall.

C. recta is found in South Europe, and grows from 2 feet to 4 feet high. The leaves are pinnate and the flowers white, fragrant, small, and borne during June and July in large terminal panicles. It is a good subject for a bed.

Other herbaceous species are *Douglasii*, *Fremonti*, and *integrifolia*.

TENDER SPECIES.

Of these there are a great many, but the majority are not of decorative value.

C. aristata is a pretty, small-leaved white-flowered Australian species, and *C. megeniana* a small-flowered plant from China with fragrant white blossoms.

C. indivisa is well known as one of the most useful of evergreen cool house climbers, and is particularly showy in late spring when smothered with its lovely white, star-shaped flowers. It is from New Zealand.

C. Stanleyi is a curious South African plant with herbaceous stems and curious woolly flowers 2 inches to 3 inches across and cream coloured.

In addition there are numerous others, but they are of botanical rather than commercial value.

W. DALLIMORE.

UTILISATION OF PEAT IN GERMANY.

NO opportunity is lost by the Germans of proclaiming their superiority to other nations as regards the application of science to the needs of industry, and there is only too much reason for conceding the justice of their claims. Particularly interesting to Irishmen is an exhibition which is now being held in Berlin, and which is entirely devoted to showing how German scientists have successfully grappled with the problem of making the marshes and bogs of Prussia add their quota to the yield that agriculture and industry extract annually from the soil of the

Fatherland. The exhibition has been promoted with the object of showing the result of the labours of a society formed in 1880 for the purpose of exploiting the waste lands of Prussia, and it is due exclusively to the services of the scientists called in to assist the society that the exhibition can boast of such wonderful success.

The exhibition is divided into two parts, one dealing with agriculture, the other with industry. In the first specimens are shown of the Beetroot, Cabbage, Potatoes, Wheat, Oats, Clover, Lucern, and other plants that have been raised on the bogs now under cultivation, whilst a series of drawings, paintings, photographs, and models shows the means employed to reclaim the land, and the systems of drainage in use. Statements of the manures found best suited to the reclaimed land are also exhibited.

In the second section are shown the industrial products manufactured from the peat. Briquettes for burning purposes, of course, figure in the first line. Then comes peat litter, which is stated to have the greatest absorbent power of any litter known and to make an excellent manure when decaying. Next comes a fabric, known in Germany as "torfmull," used in making the hygienic mattresses to be found in every hospital in the Empire, and also useful for protecting trees and shrubs from frost. This "torfmull" is further recommended as a lining for the walls of dwelling-houses, which it serves to keep both warm and dry. Paper made from peat is another exhibit, and peat paving blocks form a class to themselves. Specimens of artificial cork made from this material are on view, and the exhibitors state that it can be worked similarly to wood, can be cut or planed, will hold nails like a wall, can be painted, has the advantage of not conducting either sound or heat, and of being incapable of becoming impregnated with moisture. This cork can be rendered fire-proof by chemical treatment, and is so light that the cost of transport is reduced to a minimum. German architects predict a great future for this product, and the society hope soon to be able to build up a large export trade in it.

Germany's first aim seems to have been to endeavour to reclaim the land to agriculture, and then, in case of failure in particular districts, to utilise the peat for industrial purposes. It is hardly likely that the first portion of her programme will as yet be carried out in Ireland on a large scale, but it is to be hoped that with the quantities of similar raw material lying throughout the country some means will be found to enable Irish peat products to enter the world's markets in competition with a few at least of the articles now on show in Berlin.

T. N., in *Irish Times*.

ROSES — PAST, PRESENT, AND FUTURE.

BY THE LATE DEAN HOLE.

(Continued from page 189.)

WITH the exception of those mentioned, the Tea Roses were regarded as too tender for our English climate, and as requiring the protection of glass; but gradually we discovered (and it was my privilege to be a pioneer) that, budded low on the Briar, whether from cutting or from seed, and mulched in the winter months, they were quite safe in the open ground, and, where they had congenial soil and surroundings, acquisitions to our gardens not to be surpassed for their loveliness or their liberality. No Roses are more admired at our exhibitions, no Rose is more likely to take the prize as "the best single specimen" in the show than a perfect bloom of *Comtesse de Nadaillac*, and at home they delight us always with their diversity and profusion. Of course you may secure in the Rose house a much earlier bloom, and your flowers will not be deformed by sullen rains,

nor by that chartered libertine, the wind, which visits their cheeks too roughly; but when summer comes their beauty will be far more abundant in the garden. And when the Hybrid Perpetuals have made their first (and in many many instances, despite the proud appellation, their only) efflorescence, they will make that garden gay. Visitors have said to me, "How late your Roses are; ours are nearly over," and my reply has been, in the words of the advertiser, "Buy our carefully-selected Teas."

Then I give them the names of the best, but before I repeat this process for my readers, I must introduce them to another most charming group, allied by marriage with the two families which we have had in discussion, and possessing in combination their vigour and refinement. They are designated as Hybrid Teas, and they include flowers of such an excellent quality as to evoke the exclamation which I once heard from a young enthusiast, "I'll have that Rose, though I pawn my hat." There is, for example, no Rose which can claim precedence from La France; and Caroline Testout, Captain Christy, Bardou Job, Gloire Lyonnaise, Grace Darling, Gustave Regis, Kaiserin Augusta Victoria, Lady Mary Fitzwilliam, La Belle Siebrecht, Papa Gontier, and Viscountess Folkestone should be in every collection.

The Tea-scented Roses and their hybrids are undoubtedly at this time the most interesting varieties in cultivation, both for forcing under glass (Niphetos and La France are grown by the acre) and in the open ground. In addition to the hybrids which I have named, I commend to the amateur forming a rosarium the climbing varieties, to be planted in beds sheltered from rough weather, but in full enjoyment of sunshine, the following selection being in my belief the most reliable of their class. First and foremost Marie van Houtte, then in alphabetical order, Anna Ollivier, Catherine Mermet, Homer, Hon. Edith Gifford, Mesdames Chedane Guinoisseau, Falcot, Hoste, Lambard, Maman Cochet, Perle des Jardins, Princess de Sagan, Souvenir d'un Ami—only a sample, but sufficient to secure the allegiance of the owner and his anxious yearnings for a further association with the Teas. Farmyard manure must protect the plant and enrich the soil early in December, and the pruning knife must be applied early in April.

What shall I say of the Roses of the future? We may predict with a sure confidence that from his fond love and patient industry the rosarian will continue to add new treasures to his store. It is not only that the cult of the Rose has so largely increased, and that the places of worship are multiplied throughout the land, but the spirit of the worshipper is so much more real and comprehensive. It is no longer restricted to Roses of great size and symmetrical form, to one conventional type (though it may be of all the best), but he has a fresh enjoyment in the diversity of colour and shape which he finds in his Roses, be they double or single, little or big.

Moreover, the success of our hybridisers at home, dispelling the common idea that we had not sunshine sufficient to ripen our seed, can hardly fail to promote a keener ambition and a more splendid success in the production of novelties. Messrs. Bennett, Paul, and Dickson have shown us what can be done, and the possibility of introducing such a Rose as Mrs. John Laing should encourage a zeal in others which no failures can destroy. And it would be helpful, I think, if prizes of considerable amount were offered at our great exhibitions of Roses for seedlings of real merit which were proved to have been raised at home by English, Scotch, Irish, or Welsh rosarians.

There will be great improvements. We rejoice in the anticipation without envy; the Roses of the future, though they should be large as punch-bowls, cannot be more enjoyed than our own.

May the royal Rose enlarge her dominions and increase the happiness of her subjects until the most stubborn of all the Boers acknowledge her suzerainty. Let John Bull place Her Majesty in his coat; Jonathan, his American Beauty; the Scotsman, his Ayrshire Rose; the Irishman, Marchioness of Londonderry; the Welshman, Princess of Wales; the German, Kaiserin Augusta Victoria; the Austrian, Austrian Copper; the Italian, Pius IX.; the Russian, Empress Alexandra; the Chinaman, his Fortune's Yellow; the Indian, his Indica odorata; and let them proclaim throughout the civilised world that the Queen of all Gardens is the Queen of all Hearts!

CHRYSANTHEMUMS.

WHITE EARLY-FLOWERING VARIETIES.

THE number of white Japanese Chrysanthemums belonging to the early-flowering section is not large, and as they have a value that others do not possess their brief enumeration may be helpful to some. Mme. C. Desgrange, an old favourite for market culture, is being fast superseded. Only when grown well and rigidly disbudded can the flowers of this variety be appreciated; it is very weedy when not disbudded. Lady Fitzwygram, sent out by Mr. Agate of Havant some eight or ten years ago, is another plant that is seen in poor condition when grown freely. It will carry a dozen to twenty useful flowers, and as the habit is dwarf and sturdy it makes a pretty specimen. Bouquet Incomparable is a small dwarf sort that has little to commend it this season. The blooms are not very striking, and the habit is not good. In other seasons the plants have generally been better. Charlie is a new sort, with a rather spare habit of growth. The flowers are pretty, however, and may be described as white with cream centre; height about 2½ feet. Doris Peto is a very beautiful flower of the purest white, and in some respects is not unlike Mychett White and Market White. It is a plant that deserves to be extensively cultivated, both on account of its pleasing habit and its refined Japanese blossoms. The plant comes into flower in August and continues into October.

Grace Attick is a variety that many of the earlier growers have almost forgotten. It has quaint and curious spidery flowers of pure white, and they possess but little quality. The plant, however, is dwarf and compact. In Mrs. Squires we have a first-rate plant, not over large, perhaps, but with flowers rather larger than most others, and of true Japanese form. The flowers are pure white, and are borne on a useful length of foot-stalk; height 2 feet. Mychett White is a very beautiful pure white. The flowers are borne freely on a fairly good habit of growth, but the constitution of the plant is far from being robust. However, the flowers are so beautiful that any extra care given to the plants is amply repaid. When Owen's Perpetual was first introduced it was hoped that we had acquired a plant of promise, but it has proved disappointing. It is not very free flowering, and has a poor habit. The flowers are white, very slightly tinted pink; height about 2 feet. Queen of the Earlies is a fine large flower, much grown for market. The earlier blooms are always hidden away among the foliage, like so many of the newer Cactus Dahlias, and on this account lose much of their decorative value. The plant attains a height of almost 4 feet. Ralph Curtis, the creamy-white sport from Mme. Marie Masse, bears profusely on plants with a splendid branching habit of growth. On some soils the flowers are freely suffused a

salmon-cerise at the base of the florets. In time there is good reason to believe we shall get a pure white sport in this section of the early-flowering Chrysanthemums. Satisfaction is a plant of which little is known. This is a variety which has a distaste for wet and disagreeable weather, but in warm and dry autumnal seasons the pretty ivory white flowers are very dainty. The plant has a spare habit and a poor constitution; height 2½ feet.

Silversmith is only a passable sort, having a free display of white flowers of fair quality; height 2½ feet. Quite an unique style of growth is that seen in plants of White Grunerwalde. The habit is very spare, but the blooms are developed on single stems on a good length of flower-stalk. White Quintus is really a semi-early or mid-October flowering kind. It is a specially good sort for all forms of decoration, and individual flowers are of perfect form and of the purest white. This variety is a sport from the pink-flowered O. J. Quintus. Market White should be in capital condition by the end of September, and as it has a better constitution, or rather better than most of the late Mr. Russell's productions, a special note should be made of this variety. Cranford White is a kind of reflexed Japanese, with stiffish florets. The blooms are of good size, full, and of a white shaded blush colour. Capital bushy habit; height about 2 feet. In flower during September and later. Parisiana is one of the largest pure white flowers in the early flowering section, and of Japanese form. The habit in this case is somewhat spare, and in consequence the display is limited. Each flower is borne on a long erect footstalk. In cases where the plants have been pinched a bushy style of growth has subsequently developed. Another large flower is Mychett Gem. Milk-white aptly describes the degree of whiteness. This needs to be disbudded to be appreciated. There are a few newer white sorts, of which something may be said in subsequent notes.

Highgate, N.

D. B. CRANE.

NOTES ON HARDY PLANTS.

PINKS IN THE ROCK GARDEN.

PINKS, with their broad carpets of handsome glaucous foliage studded in spring and early summer with numerous flowers, may with justice be termed one of the chief ornaments of the rock garden; one that lacked a few representatives of this genus would be strangely incomplete. Consisting as it does of a large number of different kinds, the genus contains various species which may be used for many positions in the rock garden. Some are at home on sunny ledges, where their foliage forms a curtain over the face of the rocks, others may be planted while very small in rocky fissures or in the cracks of old walls, where they quickly take hold, sending their roots down in search of moisture and soon forming beautiful evergreen tufts. There are one or two which do not flourish under these conditions, but require more shady places in which to develop their full beauty, and some from higher altitudes need specially selected positions for their successful cultivation. Amongst the more robust spreading species *Dianthus plumarius*, with its numerous and varied forms, easily takes first place, growing almost anywhere, self-sown seedlings springing up in various places around the old plants. This may with advantage be used for covering the rougher parts and banks of the rock garden as well as old walls.

A plant with a much neater habit is our native Pink, *D. caesus*, which will succeed in similar positions. Of this species there are several forms, some with stems 2 inches or 3 inches high, and bearing large single flowers,

while others have branching stems and reach a height of 6 inches or more. *D. petraeus* is another species that forms large tufts of foliage with numerous small white flowers, while an old favourite is *D. arenarius* with its deeply-fringed blossoms. A shade-loving plant is *D. sylvestris*, which forms tufts of grass-like foliage and freely produced pretty pink flowers on stalks about 6 inches or 9 inches high. Almost the same habit as the last, but with longer grassy foliage and larger flowers, with a dark-bearded zone, is the beautiful *D. monopetalus*. All these are easy to manage, and form a selection suitable for the ordinary rock garden. For those who have a taste for choicer and rarer plants that require a little more attention, there is the alpine Pink (*D. alpinus*), which may be grown in a sunny position planted in gritty loam. Others well worth growing are *D. neglectus* and *D. glacialis*, the latter of which benefits by the addition of granite chippings to the soil in which it is planted. Another, and one of the most beautiful, is the zoned Pink (*D. callizonus*), which requires a slightly shady spot. All are readily raised from seed sown in spring in slight heat. When large enough they should be pricked off into small pots, from which they may be transferred to their permanent quarters.

W. IRVING.

IRIS RETICULATA.

UNDOUBTEDLY this is one of the most beautiful of early-flowering spring plants. I know of no bulb that repays so well for good cultivation. To those who have not tried it I would say obtain good bulbs from some reliable source; during the early autumn they can be bought for 5s. to 8s. per dozen. I consider the best time to plant them is during September and October, or they may be potted four in a 5-inch pot, planting permanently when well rooted. The best soil for them is a light sandy one; if heavy it is easy to remove a portion, adding peat, leaf-soil, or light potting soil with sand. This should be 12 inches deep, planting the bulbs at a depth of 4 inches. This is the way we grow it in a sunny border with other hardy plants, and it is no uncommon thing to be able to count fifty to a hundred blooms on one of the clumps; with us it increases rapidly. Last year the first blooms opened the end of February, and this year the first day in March. It thrives amazingly at Diddington Hall, Norfolk, where the soil is light and sandy, and equally well in North Haits in a similar soil. In our garden the clumps are divided every three years, otherwise they become too crowded.

It is charming in large patches on rockeries in association with other spring-blooming plants. Nothing is more lovely for cold houses or frames

than this, and it grows well in pots. To cut from it is charming, being light and very sweet-scented.

JOHN CROOK.

EVERLASTING PEAS IN THE WILD GARDEN.

THERE are few plants that illustrate better the idea of what we call the wild garden than these Everlasting Peas and their varieties. It is seldom one is seen in the ordinary type of garden at all; they do not come into any popular phase of gardening; the mixed border they are not particularly suited for, even in the few cases where it has not been done away with, while, of course, they are out of the question in the parterre. Thus we deprive ourselves of one of the boldest and handsomest races of hardy plants ever introduced. Now there is scarcely a place which does not offer pretty spots where these plants might be grown without any interference with the "trim garden" proper, and look all the better for separation from it. We have seen the forms of the common Everlasting Pea beautiful in hedgerows, or running over shrubs in a copse, or planted in a rough grassy

in the garden proper, and these would be equally useful and beautiful in the position we mention. In fact, there is no Everlasting Pea or long and vigorous straggling Vetch which could not be thus grown in the hedgerow, or copse, or on a fence, and for effect in mass some of the smaller-flowered Everlasting Peas would be quite as good as the larger ones. But the white-flowered forms of the common Everlasting Pea (*L. latifolius*) and its fine crimson and striped kinds are so valuable for cutting, and bear such handsome flowers, that they would be preferred, as will *L. grandiflorus*. The common forms of the Everlasting Pea are usually raised from seed, but the striped crimson and other new and choice forms will have to be increased by division. We believe the valuable white Everlasting Pea comes pretty true from seed; most of the kinds form very strong tufts when established, and good pieces of the root are not difficult to get for the purpose in the various places above named.

FUNKIAS FOR HOUSE DECORATION.

THEY who have to provide a continual supply of plants for house decoration know how difficult it is to do so with a limited number of glass houses. This is especially so when the places to be embellished are draughty or dark. In such positions plants grown in warm, moist houses are practically useless. For years I have found many hardy plants of the utmost value for this work, and especially Funkias. I am convinced if it were better known how suitable they are for decorative work they would be more widely grown.

We grow a good number of plants and of several sorts. In this way we have them throughout a long period. We find them useful in pots of all sizes, from 5 inches to 14 inches diameter. The small ones are most useful for placing in vases to go in positions where big ones

could not be placed. Large plants from 1 foot to 2 feet across—their handsome foliage quite hiding the pot—are most attractive when placed singly on tables or in any position just under the eye. We often have plants that would compare favourably with many foliage plants grown in a stove. Another position we find them of great value for is in a large fireplace, from 6 feet to 8 feet long, and wide and high in proportion; we use them as a groundwork, with a few light flowering or foliage plants such as Lilies, Gladioli, &c.

Their enduring nature is a strong recommendation. When grown cold and exposed they will remain at their best for many weeks, that is when the leafage is ripened. When they are making growth they become weakened and drawn if not changed frequently. Our custom is to place several plants early in the spring in a warm house; when growth has advanced they are removed to a cold, airy structure to harden. These are followed by another lot in a cold pit. A third batch is allowed to make growth in the open,

PINKS IN THE ROCK GARDEN.

place away from shrubs or trees. We once observed it in a neglected shrubbery. It was a wide belt which surrounded the garden, too wide to dig and mutilate except on its margin only, which was trimmed and otherwise treated in the usual fashion. But some stiff beds of hardy plants were growing near (it was a botanical garden), and from these, when digging in autumn, the trimmings of a plant of the large-flowered Everlasting Pea had been removed and thrown into the shrubbery beyond the dug part; here they rooted, scrambled up the trees and shrubs, and formed for themselves one of the prettiest little colonies imaginable, growing there year after year unmolested, because the digging, for economical reasons only, had not happily gone more than 10 feet or 12 feet from the edge. The two main types of the more showy Everlasting Peas are thus shown to be well suited for this treatment; they are plants which everybody would admire for their hardiness, beauty, and use in a cut state, but there are some other Everlasting Peas which are still less likely to get a place

being placed behind a north wall: these are useful late in the autumn. Being strong growing they need help or they soon suffer. We allow them to remain two or three years in the same pots, feeding them well. When repotting is necessary the large ones are cut into several pieces and put into small pots, others are moved into larger pots. The soil must be a good strong loam with some decayed manure, potting them very firm. This should be done when the plants are dormant. While in this condition we plunge the pots in ashes in the open and allow them to remain till growth begins or they are required for use. All large plants not wanted we plant in the open in various positions, and a group of these is most striking. When at Kew in the autumn of 1903 I saw some fine groups of *Fortunei* and its varieties, *ovata* and the two variegated forms, *lanceolata* and *sieboldiana*, *undulata*, and several others. We grow all these in pots and in the open ground, as well as *grandiflora*, known also as *subcordata alba*. This is far more tender than the others and much later. It is most valuable when in bloom in late summer with its fine white flowers. JOHN CROOK.

DRACÆNA AUSTRALIS OUT OF DOORS.

ENCLOSED you will find a photograph taken of *Dracæna australis*, which flowered in our garden this summer and was in full beauty early in July. We had the plant twenty to thirty years ago in our hottest house, where it grew too large, and was planted out in the open garden some twelve to fifteen years ago. It is now 16 feet high, and for many winters has had no protection. A few years ago it had one flower. In its earlier years the plant had but one head; now it has seven heads on the one stem. The flower is soft creamy white, and looks as if innumerable tiny bottle brushes were made up into a lovely large plume. There were, as you will see by the photograph, two good flowers this time. We suppose any severe winter it might be killed down to the ground.

FLOWER GARDEN.

COLOUR IN THE MIXED BORDER.—I.

NOW that autumn is rapidly approaching it behoves all good gardeners to study well the state of their herbaceous borders. The time is coming when the usual revising and correcting must be done, large plants divided, unruly ones checked, and the failures of the past season taken to heart, and preparations made to ensure a greater perfection in the year

DRACÆNA AUSTRALIS IN A CAMBRIDGESHIRE GARDEN.

From a photograph kindly sent by a correspondent at Wisbech.

(This plant is 16 feet high, and has been in its present position in the open for twelve years. For many winters it has had no protection.)

to come. The cultivation of hardy flowers in our gardens and borders has long been a delight to the amateur gardener, and every year the taste for this form of floriculture seems to increase. No garden, whether large or small, is now complete without its border stocked with perennial and biennial plants, supplemented by the yearly addition of hardy and half-hardy annuals, and every gardener has his own views on the selection and arrangement of the various plants, so that they shall form what is in his opinion a continual and beautiful sequence of colour and sweetness from March until the frosts destroy the last lingering blossoms in November.

To succeed in this delightful and absorbing labour of love is another matter, for we all know it is full of difficulties, and perfection is very rarely attained, particularly when the borders are on a large scale. I am convinced there is nothing in the whole art of gardening that demands so much time, so much patience, and so much botanical knowledge as the making, arranging, and the maintaining in perfect order of the mixed border. To begin with there is the

MAKING, which must be so thoroughly done that the soil need not be disturbed for years. Then there is the judicious selection of such plants as shall thrive in certain conditions of soil and position. You must remember that, save for yearly sub-division, these plants will probably remain there in perpetuity, and it is well that they should, for in many cases the old-established clumps of hardy perennials are the most satisfactory. The simplicity of the borders of old-fashioned garden flowers beloved by our grandmothers is a thing of the past: we now have a hundred different plants where they had one, and these are gathered from all parts of Europe and Asia—from high and low altitudes, wet and dry places, even from the alpine snows—and we crowd these beautiful foreigners among our hardy old friends without the slightest regard for their requirements. What wonder if the so-called herbaceous border is too often a heterogeneous mass of floral failures! But there seems no tendency to return to the simplicity of old gardening ways and to be content with white Lilies, Hollyhocks, the Sweet Williams, and the Stocks of bygone days; rather is there a determination to make border gardening as complicated as possible. I allude to the phase that is rapidly gaining favour among many enthusiasts, whereby we are too surely increasing its pains and difficulties—this phase is the planting of

flowers in sections of one colour, so that throughout the spring, summer, and autumn the colours will be kept quite distinct and massed, so as to avoid the spotty effects much depreciated by the artist-gardener. The commencement of this mode of floriculture can be traced to the very meritorious idea—started, I believe, in Hyde Park—of planting groups of the same plant instead of single specimens, and, for reasons I shall state hereafter, I think the first idea was far more practical and artistic than the last. Frank Miles, who was gardener as well as artist, did not ask for or require any formality in the planning of his borders; like all true artists he went straight to Nature for his ideas, and, seeing a field of wild flowers in early summer, he noted how all tints were blended and rendered harmonious by the tender green of the mingling herbage, and he adopted the same arrangements, using foliage plants plentifully. He brought together flowers from other lands, but he studied their needs with loving care, and speedily created a veritable paradise of sweetness and harmonious beauty. To him we owe the common use of Lilies, once supposed to be too delicate to stand our rigorous climate, and I well remember the surprise of the gardening world when Mr. Miles showed it—the *Lilium longiflorum*—growing in masses among the cottage flowers in his father's garden at Bingham. The *Lilium candidum* and the Tiger Lily were then the only Lilies commonly seen, and now there are a great number of exquisite sorts all capable of use in one herbaceous border.

In a garden I wot of, beneath a great arch of Crimson Rambler, unbound and untrammelled and flowering profusely, were tall, noble spikes of *Lilium candidum*, and close at hand in charming contrast, and making up the harmony of red, white, and blue, towered fine masses of *Delphinium azureum*. The fairest of all Lilies were splendid this year, and in this case, being plentifully watered and in partial shade, had retained their foliage. I do not think Frank Miles could have known of the lovely *Lilium rubellum*, which I saw for the first time last June flowering in woody places at Wisley, the Royal Horticultural Society's beautiful new possession in Surrey, tinting the mossy turf like a sunset cloud.

The herbaceous borders where grow the Lilies and Crimson Ramblers I mentioned are very extensive, being 130 yards long on each side of a turf-edged gravel path. They are backed by Laurel hedges, charming theoretically, but making severe demands on the soil, which has to be constantly supplied with plant food. The hedges' tender green is broken here and there by Lilacs, Laburnums, *Kerria japonica*, and Berberis. Behind the hedge on each side are Apple orchards, and blossom-wreathed boughs in the spring time almost overhang the borders, adding their own beauty to the galaxy of spring flowers beneath. In March the golden host of Daffodils pierce with their swords the moistened earth, and herald in the long procession of flowers. The pretty *Chionodoxa*, the Primroses, double and single, of every shade, and the laced *Polyanthus* flower unchecked, increasing with the Narcissi year by year. In front, close to the broad margins of velvet turf, the border is carpeted with purple *Aubrietia*, Rock Cress, blue and yellow *Violas*, and *Alyssum*. Tall cottage Tulips and *Hyacinthis* follow closely, and Wallflowers, and blue Forget-me-nots complete the charming crowd. Of course one of the difficulties of a mixed border is the dying down of the Daffodil spears, and the decay of other bulb foliage, and a dull week or two is inevitable after the sunlight of a thousand Daffodils passes from the borders.

The Spanish Irises that come to our aid so beautifully tarry awhile, and by the time their dainty purple and yellow and sapphire blooms are fully out all the series of early summer flowers have answered their roll-call. The Lupins, light blue and dark blue, purple and white, and yellow show their spikes bravely, and the real old-fashioned Columbines, double white and blue and vari-coloured, shake their little petticoats in the soft May breeze. The great daring scarlet and crimson Poppies dazzle our eyes, and we turn with relief to the cool blue of the *Delphiniums* and the charming *Erigeron speciosus*. There, too, are the pearly *Achilleas* and white Mallows, and the white and lilac *Galegas*, sweet and homely, but apt to encroach too much unless controlled, and a hundred other old and tried friends of the border.

This is the supreme moment for the herbaceous garden, and as we gaze down a long vista of beauty we feel we have been repaid for months of toil. Life has no greater joy to offer. Every day for six happy weeks fresh beauties smile on us, and some forgotten treasure or some new plant discovers itself to us, peeping from behind a Peony, or playing hide and seek from a mass of pink *Pyrethrum*. We refuse to be disconcerted if the blanks left by the Daffodils and *Narcissus* declare themselves, for in our reserve garden there are plenty of plants which can be put in at a moment's notice, and we have sown annuals which will fill up the vacant spaces rapidly. Some gardeners pull up Tulips and store the bulbs for another season. I never do this, and both my lovely Cottage Maids, and my later-blooming Parrot Tulips reward my reticence by flowering better every year. I am sure the reason of their superior beauty in the cottager's garden is that they are never interfered with.

The cottager has no time for the intermeddling which is the ruin of so many lovely things. *Violas* and Forget-me-nots, too, will cover prettily the unsightly stalks. Frank Miles used *Oxalis* for carpeting between his hardy flowers, and on sunny borders close-growing plants are of great use in keeping down weeds and providing moisture round the roots of any thirsty occupant; and then, too, you get the green, which is of so much value.

The little *Veronica prostrata* is a charming plant for carpeting; its profuse flowers in early summer are of a beautiful blue, a colour always so much wanted, and its foliage is very neat and compact, and though it increases rapidly it is never a tramp—I mean by that it does not turn up all over the border, and even find its way on to the gravel path, as do some troublesome botanical things. Then, as we drift too rapidly into autumn days and autumn ways, again a dull time is inevitable in our gardens, but if we ent off all the seed-pods from our annuals and perennials we shall prolong the hours of radiance and beauty that are so fast running out.

The Canterbury Bells, well cared for and given frequent doses of liquid manure, will blossom again better than ever, and are even more appreciated than when we had a greater wealth of bloom. The *Delphiniums* and *Pyrethrums*, cut down rigorously and given plant food liberally, will bestow on us again their delicate azure and purple spikes and their various Daisy-like blossoms, and in addition we have the *Phloxes*, carefully chosen from a long list of new beauties, the early and late perennial *Sunflowers*, and the summer *Chrysanthemum*, the crimson *Lobelia* Queen Victoria, too little known, and the charming *Salvia patens*; then we must not forget the *Montbretias*. The Iceland Poppies flower

again very nicely if the seed-vessels are cut off and the plants tidily trimmed. Then the Michaelmas Daisies come creeping out and the tall *Chrysanthemum uliginosum* and the *Helianthus* make our borders purple and white and gold. Dahlias we do not like in our borders, for the first frost blackens their foliage disastrously, so they must dree their weird in a bed apart. But it is time to conclude an article that has already exceeded its limits. I hope in my next to discuss what plants to grow for the mixed border, and their annual preparation in the reserve garden, and I propose to make some suggestions for herbaceous bedding in colour sections, and I shall also describe a successful border so treated.

AUGUSTA DE LACY LACY.

A GENERAL CALENDAR.

ROSES IN POTS.

WHEN the pot is crowded with roots repot the plants. The best plan, however, is to glance over the stock occasionally through the summer months, and whenever a plant is seen growing vigorously always repot it, but a general repotting should take place at least once a year, and September is undoubtedly the time for it. A good portion of the old soil should be shaken away, all suckers and worms removed, and such plants as require it placed in larger pots.

Tea-scented Roses.—Every collection of pot Roses should include a quantity of these. The flowers are generally large, and the colours in some cases remarkably rich, and in others peculiarly soft and delicate. Some of the varieties cannot be depended on in all soils and situations when grown in the open ground. They vary much in degree of hardiness, but all are sweet, and many of them are excellent for forcing.

Carnations for winter flowering.—Border Carnations are generally layered as early as possible, and it is not always easy to discriminate between the grass and the flower shoot, consequently many of the latter get layered. These, if carefully removed from the parent plant and potted up in good soil, leaf-mould and sand, with careful handling grow on and flower for a long period in a house that is just sufficiently warm to keep out frost, thus adding greatly to the Tree varieties, which by that time may or may not be in bloom.

Apples.—This crop, taking it as a whole, is fairly satisfactory throughout the country, and the quality of the fruit bids well to be far above the average. Most of the early varieties are good in colour, and of excellent flavour. Judging from present appearances, the later varieties will be good also. Those who wish to make their Apples cover as long a season as possible should prepare for gathering. It is generally accepted, but an erroneous idea, that Apples keep best when allowed to hang on the trees as long as possible before gathering, but I have found by experience that such is not the case. Most Apples, especially the early varieties, keep best when picked as soon as they will part from the tree with their stems intact. The general tendency is to leave the early Apples too long on the trees, whereas they might be housed where they will be out of the reach of birds and wasps.

Shropshire Damson.—The fruit of this variety is much larger than that of the common black Damson, and more oval. This is a better variety than the common sort for preserving, and makes an excellent jam. In 1895 I planted ten young Shropshire Damson trees in the gardens here (Ashwellthorpe Hall, Norfolk). I have gathered some fruit almost every year, and this year I have gathered an excellent crop from all the trees. This will show that Shropshire Damson trees will fruit in other counties besides Shropshire.

Winter Turnips.—The latest sowings of these should now be made on land held in readiness for the same. Turnips as a rule are not needed of

greater size than a cricket ball, and if sown in September the roots will be large enough. Small roots keep better; they are sweeter and more solid. It will be well in case of any deficiency to sow a few rows of the Early Milan type for present use. These do not keep, but they provide roots in advance of the winter sorts. Now is a good time to sow the yellow-fleshed Turnips, as these are hardier, keep longer, and the quality is equal to, indeed, often better than, the white-fleshed varieties. Where Turnip tops are in requisition these will furnish a good supply in the spring when other vegetables are sometimes scarce.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

DAMSONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In your leading article (September 10) you infer that Kent growers only cultivate the Farleigh Prolific or Cluster Damson. As large raisers of trees for the market planters, we beg to say that we have for many years sold thousands of other kinds. Before naming them we would remark that the Farleigh Damson can be, and is, raised from suckers, and such trees have been largely planted because they are cheap, but they form hard, knotty stems, topped by rugged, thorny heads, and the fruits are small and wanting in flesh. On the other hand, trees worked in the usual way by budding make clean, straight-stemmed trees, with free-growing heads, and the fruits are double the size of those from suckers. It is still planted because it is a tremendous bearer; but for quality, combined with fertility, there is none to beat Bradley's King of Damsons; this makes a pretty, compact tree. Another variety, the Frogmore Damson, grows more like a Plum, and bears large and delicious fruits, and is valuable for an early picking; it is quite good enough for dessert. An older and largely-planted variety is the Shropshire or Cheshire Damson. This hangs often into November, and is called in the market the Prunt Plum or Prune Damson; it makes a flat-headed, weeping tree, with large leaves, and bears freely every few years; when fully ripe the fruits are very good for bottling, tart or jam. It is the largest variety. We have grown the Prune of Hereford, a small-leaved tree of upright growth, but discarded it, as we never yet had a satisfactory crop. The Damascene of Evesham is a very fine large Damson in that district, and is raised from suckers, but with us it takes years to form a tree, and is so thorny and of such spindling growth that we fail to get buds. Rivers' Early Damson is useful in the Plum season, and the White Damson is good for a late supply.

Maidstone.

G. BUNYARD AND CO.

LABURNUMS ON ARCHES AND PERGOLAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—How effectively Laburnums can be employed on pergolas and arches I have lately had many opportunities of seeing. Lord Battersea in his charming garden at Overstrand in Norfolk has employed this plant with good effect. Some years ago short standards were planted on each side of a path and the branches arched over, the drooping racemes producing a glorious mass of colour in early summer. The pillars of the pergola, built last year, are 10 feet high and as much apart. To connect the pillars on the top large, untrimmed, peeled Oak branches are used. Here and against the pillars are planted standard Laburnums; the branches quickly reaching the top are trained along the Oak beams and make a fine display. At West Dean Park, near Chichester, Mr. W. James has an archway 70 yards long, 12 feet wide, and 8 feet high. This archway is completely covered with branches of the Laburnum, which are carefully pruned or spurred back, so that a full

crop of yellow blossoms is secured annually. To relieve the somewhat naked base of the tree stems and each end of the wooden archway frame Irish Ivy is employed most effectively. The ordinary Laburnum vulgare is usually employed, as it gives abundance of flower. The Scotch form of *L. alpinum*, with its longer racemes, larger and more handsome foliage, would be quite suitable for a taller structure. This, in my opinion, is quite the best of Laburnums.

E. MOLYNEUX.

THE GARLAND ROSE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I enclose a photograph of the Garland Rose growing over an arch in my garden. It has been very much admired this summer.

Tynham, Wareham, Dorset.

MRS. BOND.

DESTROYING WASP NESTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—To destroy wasp nests soak a piece of rag in turpentine when all the wasps are at home. Push the rag into the nest with a stick and cover the hole with a piece of turf, stamping it down. If

THE GARLAND ROSE IN A DORSETSHIRE GARDEN.

there is more than one entrance to the nest do the same to each. When the buzzing ceases (in about ten minutes) dig out the nest and destroy the grubs which otherwise would hatch out. There is no need to set light to anything, as it is quite effectual without this.

Buxted.

F. V. H.

THE PLUM CROP.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I note in a recent number that a correspondent, writing of Plums, says they are hardly required after September. It is a question if this is the general experience, certainly I have not found it so; on the other hand, they are welcomed as long as they can be supplied, alike for dessert or cooking purposes. For the latter especially they are in demand all through October, as a change from Apples, stewing Pears, and late Currants and Cherries. November 10 is the latest date I have gathered within the last few years; both Coe's Late Red and Blue Imperatrice were very fair in quality on that date, and a consignment picked then for bottling purposes turned out in splendid trim at Christmas. The principal object of this

note is to suggest the advisability (when planting operations are in progress) of a judicious selection to follow each other in their respective seasons, both for dessert and kitchen, and not to plant a lot of sorts that would ripen together. A careful selection will give a succession from the third week in July until the beginning of November. Like all other fruits, Plums vary considerably on different soils, and it is well before planting largely to have the experience of a grower who makes fruit trees a speciality. Here, in West Surrey, with a light soil and sub-soil, I find Oullin's Golden Gage, Green Gage, Transparent Gage, Jefferson's Reine Claude de Bavay, Coe's Golden Drop, and Ickworth Imperatrice for very late work the best for dessert, and Early Prolific, Czar, Kirke's Victoria, Pond's Seedling, and Coe's Late Red the best for culinary purposes. Our Plum wall, 150 yards long, is always protected in spring with a double thickness of $\frac{1}{2}$ -inch mesh netting as the blossom, especially when erect, is very susceptible to frost. A correspondent in a recent number, when writing of the Nectarine, raised a doubt as to its hardiness. Did that refer to the blossom? If so, my experience is that Nectarine flowers will come unscathed through weather which would render a crop of Plums an impossibility.

Esher.

E. L. B.

OVERCROWDED SHRUBBERIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Judging from the planting going on around us the chief object appears to be immediate effect. This may be well enough in some cases, but at the best it is a wasteful method, even when one feels quite sure someone is coming after us to do the necessary thinning and give a timely check where there are too many leaders or the tree is developing unequally. Every planter ought to make himself acquainted with the average height and dimensions that the trees will have when they reach full development and arrange the sites for the permanent features first, then filling in with temporary things. Usually the mistake is made in planting what are called "nurses." If the situation is bleak and exposed plant the nurses in a belt outside, and the really good and choice things will not be crowded out and ruined by them. There are plenty of what one may term "wind-resisters," suitable for seaside or other exposed situations. The common Gorse where there is plenty of room makes a capital wind-break. After the Gorse might come the Austrian Pine in a double or treble row from 8 feet to 9 feet apart. A few Canadian Poplars may be mixed with these till the Pines grow up, when they may be gradually cut out. This Poplar bears cutting well, and makes a splendid hedge 12 feet high and a good wind-break even in winter when the leaves are down, as the twigs, from frequent cutting back with the shears, form a dense thicket of branches. Inside a shelter of this kind you may carry out any kind of gardening in the most perfect and satisfactory manner. Instead of filling in the shrubberies with common things till the better sorts get up, fill in with groups of hardy plants.

Annals will come in useful, especially near the margins—masses of Lupins, Malvas, pink and white single Hollyhocks, Michaelmas Daisies, Foxgloves, yellow Evening Primrose, and herbaceous Phloxes. I think the effect is better when irregular-shaped patches of distinct colours are planted. Large patches of white and crimson Phloxes, white Foxgloves, and yellow Evening Primroses are charming among dark-leaved trees and shrubs; in fact, I should be inclined to plant the permanent trees and large-growing shrubs at rather wide intervals, for the express purpose of leaving spaces for effective groups of hardy plants. Antirrhinums are simply splendid for massing in distinct colours among shrubs till the latter get up and overpower them. *Lunaria biennis* (Honesty) is a very useful plant for banks and rough places, and once started will take care of itself. Snowdrops, Winter Aconites, Wood and other Anemones, and Lilies of various kinds, including Lent Lilies (so-called), are appropriate, as are also Solomon's Seal and Lily of the Valley. If the ground is trenched

before planting there will be no work for the man with the spade. Weeds can be kept down by using a small hand fork and a small Dutch hoe, but the plants will keep down weeds if the ground is thoroughly prepared and cleaned before planting. E. HOBDAY.

MESEMBRYANTHEMUMS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—A considerable amount of uncertainty exists in the nomenclature of the Mesembryanthemums, the description of the blossoms of many species in the horticultural dictionaries being often utterly dissimilar to the flowers borne by plants grown under the same names in some of the best collections. Doubtless in the list given by "K. L. D." of the most desirable species the names are correct, but I confess to being somewhat surprised that *M. acinaciforme*, *M. tenuifolium*, and *M. roseum* are not included in the selection. The first-named has the largest flowers of any Mesembryanthemum with which I am acquainted, the blossoms being slightly over 4 inches across and of a deep rose colour. An illustration of this in flower in the open in South Devon appeared in THE GARDEN on page 362, Vol. LXII. The foliage is almost identical with that of *M. edule*, but the flowers are larger and far more attractive in tint. *M. tenuifolium*, as grown in the fine collection at Abbotsbury Castle, Dorsetshire, is the most brilliant of the whole race, the flowers being of a dazzling scarlet; a large plant, a sheet of bloom, was such a mass of glistening brightness in the sunshine that it was almost impossible to keep the eyes fixed on it. I was informed that this had been named at Kew, where *M. acinaciforme* was named from flowers sent by me, so that the titles of these two species may be taken as correct. The plant generally grown under the name of *M. roseum* is a most profuse bloomer. An illustration of this growing in the open in South Devon appeared in THE GARDEN on page 363, Vol. LXII. As, however, flowers have not been submitted to Kew, it may possibly be incorrectly named. I notice that in "K. L. D.'s" list *M. amoenum* is given as rose. Many years ago I brought from the Cape a scarlet Mesembryanthemum, which I sent to the head gardener at Abbotsbury. A year or two after, on visiting the gardens, I found it in flower, and was pointed out *M. amoenum*, as grown at Abbotsbury, as being identical with it, which it certainly appeared to be. The plants were bright scarlet, but on comparison with *M. tenuifolium* the latter was thought to be rather more brilliant. The foliage of both was very similar.

S. W. FITZHERBERT.

NURSERY GARDENS.

NEW ROSES AT WALTHAM CROSS.

AS every rosarian is aware the old town of Waltham has given its name to many beautiful Roses, such as Beauty of Waltham, Star of Waltham, Pride of Waltham, &c., and it says much for their quality that they are found to-day in almost every exhibition-box, although some of them were introduced upwards of forty years ago.

Our quest on this occasion, however, was not old but new Roses. We were, nevertheless, glad to renew acquaintance with many a flower of bygone days. Probably there is no nursery in this country where such extensive collections of Roses are grown as at Waltham Cross. Before the war in South Africa the firm fulfilled an order for a thousand varieties for the Cape, and every one who has watched events knows full well that the novelties since that time have been prodigious.

There is no place like a good nursery to gather information about the best varieties for massing in quantity. At Waltham Cross one may find the popular varieties grown by the thousand. The pot Roses were excellent, and no wonder the firm were enabled to gain the 50 guinea cup at the

Temple show this year for the best individual exhibit from such an abundance of material here displayed.

The work of hybridising the Rose is carried out at Waltham Cross in a thoroughly systematic way under glass. The splendid pods of ripening seed, some as large as small Pears, and produced upon all up-to-date sorts, as well as upon the firm's own especial strain of Riviera Roses, will surely yield a rich harvest of beautiful novelties, and we can only hope that Mr. William Paul will live to see many more triumphs of the firm which he has done so much to establish. To mention a few of the recent novelties introduced or about to be introduced the first to name is

Earl of Warwick.—This was seen in splendid form, and we prophesy this Rose will be wanted in every garden. The flower displays a beautiful combination of tints, the prevailing hue being salmon-pink with vermilion centre. The huge petals are as fine as those of *G. Nabonnand*, but it is in its high centred form equal to an exhibition Rose, although not too full for garden decoration. Apparently the growth is as free and robust as Viscountess Folkestone and similar sorts.

Countess Cairns is a seedling from President and Caroline Testout. This is also a beautiful decorative Hybrid Tea, the colour being cerise-carmine, flowers very large, but not full. They are borne erect, on fine vigorous growth, which makes the variety an excellent addition to decorative Roses.

Irene is another seedling of Caroline Testout, crossed with the beautiful Hybrid Tea *Mme. Jules Finger*. This Rose is really a white Caroline Testout, the flowers being pure in colour and of finer form than other white varieties of this popular Rose.

Mrs. A. Byass completes a quartette of beautiful novelties for this year. The latter Rose seems to combine the good points of four beautiful sorts, viz., *Comtesse Festetics Hamilton*, *Beauté Inconstante*, *Christine de Noû*, and *General Schablikine*. The colour of *Mrs. A. Byass* is madder rose, shaded with crimson, and there is an extraordinary tendency to variation in the flowers. Another decorative Tea that has a great future is

Warrior.—This may be described as a deeper coloured *Papa Gontier*, although the plant is more vigorous. The colour is certainly deeper, the buds being quite a mulberry-crimson.

Messrs. Paul will distribute next year two very fine Hybrid Perpetuals. One is named after a very skilful rosarian,

David R. Williamson.—The colour is bright cerise. The flowers are large and of splendid form. It will be a grand show Rose.

Messrs. Paul are also hybridising amongst the popular ramblers and trailers and other types. Their Waltham Rambler is now well known. If late flowering ramblers are desired, so also are very early sorts. At present they are comparatively few in number. Messrs. Paul have a beautiful variety for distribution next year. When in bloom early in June it is a perfect avalanche of snowy-white flowers. The variety which has not yet been christened might almost be called a rambling *Mme. Plantier*, only the individual flowers are more beautiful. It will make a fine companion to *Carmine Pillar*, *The Dawson*, &c. Two fine wall climbers are *Field Marshal* and *Golden Queen*, a beautiful and taking golden colour. We saw at Waltham Cross a batch of pot plants of that beautiful new decorative Rose

Etoile de France.—The flowers are as large as those of *Duke of Teck*, and of a beautiful crimson colour, buds deep and handsome, and a delicious fragrance. The growth is as free as *Mme. Abel Chatenay*, from which variety *Etoile de Lyon* was raised. It is also perpetual. The raiser, M. Pernet Ducher, will be justified in regarding this as one of his greatest triumphs. We understand the variety will be distributed during the coming season. We saw large breadths of the many excellent Waltham Cross novelties of the last few years, among which we may mention *Morning Glow*, *Sulphurea*, *Corallina*, *Arethusa*, the first yellow China Rose, *Elizabeth Kitto*, a dwarf bedder, *Dainty*, well named with its egg-coloured blossoms tipped red, *Fortuna*, *Chameleon*, &c., and the vigour and

splendid branching habit of most of the kinds impressed us as being excellent traits in garden Roses. Exhibition Roses receive two fine additions in *Boadicea* and *Corona*. Low hedges of Roses are a delightful feature of the modern Rose garden. A worthy addition to the number of useful kinds for this purpose is *Floribunda*, well named, as it is indeed a mass of blossom, with every flower of perfect shape, and a dainty rosy flesh colour. It will be seen that there is no want of novelty to select from at the present day whatever one may desire to plant. Messrs. Paul have also some hundreds of seedling Roses upon trial, many with pedigrees that are most promising, and we shall watch their development with interest.

THE FRUIT GARDEN.

A VALUABLE EARLY DAMSON.

IN the northern part of the country the ordinary Damson will not thrive as well as one could wish (of course there are exceptions); I have seen many gardens where these trees fruit very sparingly, and the growth is poor. The early Damson I have seen thrive when others have failed is known as *Rivers' Early*. It is a seedling from a Plum *St. Etienne*, a heart-shaped early dessert variety, not large, and the seedling resembles it in this respect, as it is not unlike an early Plum, but with a distinct Damson flavour. It ripens early in August, but this season it is later than usual, and the trees are more like the ordinary Damson, having downy shoots. This Damson was given an award of merit on the 14th ult. by the fruit committee of the Royal Horticultural Society, so that it will be seen it is a much earlier fruit than the common sort, and it is a very good cooking fruit. Being so distinct from the others it will be found a welcome addition in gardens where small stone fruits are required. I recently saw the *Early Damson* grown as a bush, and the result was excellent. Though it is well to have a small part of the stem clear of the soil, the trees grown thus escape rough winds and the fruit is more readily gathered.

A NEW AUGUST PLUM—HERON.

THIS is one of the recent introductions, and this season the crop has been so good that I have placed it in the front rank as a valuable cooking variety. In past seasons *Heron* cropped when others failed, and this made it a greater favourite. This season, however, we have it by the side of *The Czar*, and it is cropping in the same free way; it is a most useful variety to follow the last named. Some growers describe it as a kitchen and dessert variety, but I am inclined to class it as a culinary fruit, as it is a very good cooking sort, and crops when others fail. This also is one of the Sawbridgeworth seedlings. *Heron* is a variety that will be more liked as it becomes better known. It is a large purple and red fruit, and the trees grow freely in most soils. Here at Syon Plums are not at home, the soil being light, resting on gravel, but the variety described is one of our most reliable fruiters, and should be a good Plum for amateurs who only have limited space and can only grow a few varieties.

PLUM THE CZAR.

THIS Plum is so good this year that a brief note as to its value may not be out of place. In the Thames Valley *The Czar* is a great favourite in most gardens, especially for market. This is another of Messrs. Rivers' seedlings, and is called a kitchen or dessert variety. For dessert it must be allowed to hang until full ripe, and then it is sweet and refreshing. I think its earliness is its chief value; it also crops freely and cooks well. It is as early as the *New Orleans*, a very profitable market Plum. The fruits do not crack in wet seasons like those of some sorts, and the tree succeeds in any form, but as a dwarf standard I

think it the best all-round early August Plum we have. In the North The Czar on a west wall rarely failed to crop.

APPLE BEAUTY OF BATH.

It is interesting to note how firmly this handsome early dessert Apple holds its own at some of the flower shows about the country in which dessert Apples are exhibited. It is pre-eminent for its attractive appearance, being handsomely marked with bright red. It possesses a brisk flavour, and when it becomes well established bears freely. This, with Mr. Gladstone, Irish Peach, Devonshire Quarrenden, Red Astrachan, and Lady Sudeley make up a useful half-dozen varieties for August, September, and October. R. D.

A SEPTEMBER PEAR—DR. JULES GUYOT.

For the past few seasons this Pear has proved so reliable that I consider it is well worth a note as an early fruit. It is a large fruit, not unlike Williams' Bon Chrétien; indeed, it is difficult to tell them apart when on bush trees, but as a standard the newer variety is more compact. As a keeping Pear it is of no value whatever, but for use at the end of August and early in September it is worth room on account of the good crop it gives. Its greatest fault is that if stored it decays quickly at the core, so that it should be eaten a few days after being gathered. The fruit is quite different from Williams'; it has not got the peculiar flavour of the last named, and the flesh is very tender, melting, and juicy. When the fruit is gathered at the right time and eaten soon it is excellent. The fruits are handsome, the skin a pale yellow, with crimson blush on the sunny side, and the best results are secured when the Quince stock is used. It is then a compact grower, and when its size and free cropping are considered it is a useful Pear for amateurs. As an espalier or cordon it is very handsome, but the fruits should be thinned. It is excellent for market, as it commands a ready sale. G. WYTHES.

FIGS IN THE CHANNEL ISLES.

Figs have always been largely and well grown in the Channel Islands, in the first instance, of course, in the open air, before we exported fruit. In those days large trees were trained flat over wooden framework, varying in height from 4 feet at the front to 6 feet at the back. Many of these trees are still grown for supplying fruit in its natural season. When forcing came into favour many of these large trees were covered with glass, and in some instances pipes and boilers were employed. The increase of profit was of course very great, but many of the trees so treated died after a few years. This no doubt was largely caused by lack of water during the winter and early months of the year. A few large trees which would now be valued were actually cut out owing to prices falling for a time. Some old trees under glass, however, are still doing well. But the new grower now generally grows pot plants, or small trees planted on the floor and trained over the roof. In the latter case root-pruning is found to have excellent effect in restricting excess of vigour. Generally speaking, the crop may be looked upon as profitable. Figs are still not generally liked, however, so that it would probably be easy to glut the market. It certainly would not be wise for a grower to go in too largely for Fig culture. Many varieties have been tried, but Brown Turkey alone appears to meet with general favour. It is found to be much the most reliable and productive, and these, of course, are points that a market grower attaches most importance to. The right selection of varieties is very essential in fruit culture for market. A CHANNEL ISLAND GROWER.

GARDENING OF THE WEEK.

FLOWER GARDEN.

CARNATIONS.

LAYERS which were pegged down last month are now rooted and fit for removal. As a rule, there has been sufficient rain to thoroughly moisten the soil, but if there is the slightest suspicion of dryness at the roots the beds should receive a thorough watering some hours before the layers are taken up. The connecting stem must be cut with a sharp knife and the young plants lifted with a good ball of soil. Set the plants out at a distance of from 12 inches to 18 inches, according to the robustness of the variety, and plant fairly deep and firmly. If the plants are likely to be blown about by the winds, a few short, stout sticks placed around the stems will keep them steady. If necessary apply water after planting. On bright days a syringing or damping with a fine rose can will prevent flagging. Marguerite Carnations require the support of neat stakes, and the surface soil should be frequently hoed. If the bed can be afforded some protection during heavy rains and

done before the growths become tough and hard to cut. This work should be done with great care and judgment, as any mistakes that are made will be apparent for many months.

HERBACEOUS BORDERS.

Now that the dull portion of the year is coming upon us, the greatest neatness and cleanliness are more necessary than ever. Many of the early-flowering annuals that are spent should be entirely removed. Such gaps may be filled with spare plants of *Doronicums*, Wallflowers, &c. All dead flowers and seed-vessels must be constantly cut off, and with herbaceous plants, which are becoming shabby, they should be cut down to the ground. Michaelmas Daisies are beginning to make a show, and any tying of these that may be necessary should be done with a light hand. The heavy dews tend to increase the growth of the lawns and of weeds in the walks. A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

DORONICUM PLANTAGINEUM.

WHAT a useful plant this is for growing in pots to flower very early in the spring. No attempt should

FIG TREE TRAINED OVER HOUSE ROOF IN THE CHANNEL ISLANDS.

when frosts are expected the flowers will be much cleaner and their season prolonged.

VIOLETS.

As they appear all runners should be removed to restrict the plants to one crown. Frequently stir the surface soil and remove all weeds. An occasional syringing with weak liquid manure water, well wetting the under surfaces of the leaves, will keep down red spider.

WIND AND WALL PLANTS.

With the autumn equinoctial gales may be expected, and it will be wise to examine all wall plants to see that they are securely fastened. Plants of doubtful hardiness should be kept well thinned and have all soft shoots removed, as thoroughly ripened growth stands a better chance of passing through the winter. The side growths of Roses on walls or fences may be shortened to 12 inches or 15 inches and superfluous growth removed. Box edging should now receive its last clipping, and all hedge pruning and topiary work

be made to force—by artificial methods—the plant early into flower; better far to pot up at once portions of the roots, and keep them well watered. The roots of plants that are potted up early make growth, and become semi-established in the pots before severe winter weather commences. At the proper time there is no difficulty in bringing plants so prepared into flower with practically no artificial aid.

ANEMONE FULGENS (SCARLET WINDFLOWER)

is another neglected but very useful plant for growing and flowering in pots early in the year. Pot up the bulbs early, and afterwards plunge the pots in sand, where they can make plenty of roots. In a porous light soil the bulbs will root freely, and directly top growth commences remove them from the sand-beds to any position that is cool, light, and airy.

ROSES IN POTS.

The stock of these required for early forcing should be thoroughly overhauled, and while a few

may need moving to larger pots, the majority, perhaps, will require only to be top-dressed. Discontinue giving manures, and see that the crock holes at the bottom of the pots are perfectly clear. Afford them the most exposed position, where sun and frost also can reach them.

TUBEROUS-ROOTED BEGONIAS.

Although these plants are beginning to lose their flowers and foliage, it is a mistake frequently made to discontinue the application of water to their roots so that the foliage flags, for their thick fleshy stems shrivel prematurely. Directly the plants become unsightly remove them to the frame, where they can be given water as required, and where the bulbs—through keeping their stems and foliage in a healthy state—will mature properly, and be in a condition to keep well throughout the winter.

KALANCHOE FLAMMEA.

Cuttings made from the young side-shoots should now be inserted, the strongest singly in 2½-inch pots, and the weaker ones from six to eight in 4-inch and 5-inch pots. These will root freely, and before winter weather sets in will be ready for potting singly. With care afterwards they will grow steadily throughout the winter, and be ready in the spring for removal to their flowering pots.

CROTONS.

Good, well-coloured cuttings of these are more easily obtained now than at any other season, and, if taken off and rooted, they can be grown steadily on through the winter, and will, with good culture, afterwards develop into fine, handsome, single-stemmed plants, useful for grouping during the early part of next summer. J. P. LEADBETTER.
The Gardens, Tramby Croft, Hull.

FRUIT GARDEN.

PEACHES.

THE second early trees should be root-pruned if necessary. To do this cut out a trench deep enough to reach the drainage 3 feet or 4 feet from the stem, according to the size of the tree. Cut off any strong roots and partially lift some of the others, returning some of the same soil with an addition of fresh compost. In planting fresh trees see that the drainage is good, prepared of broken bricks, and covered over with lime rubble, afterwards placing turves grass side downwards. The compost should be good turfy loam, mortar rubble, and wood ashes, with a fair sprinkling of bone-meal, returning with it a fair proportion of the old soil. In removing a tree open out a trench about 4 feet from the stem, and carefully reduce the old soil with a fork, leaving a mass of roots and soil that can be conveniently removed on a hand barrow without breaking. Plant rather high and keep the roots at different levels near the surface. Cut back any strong roots and those that are damaged, and make the soil firm. Give a good watering, frequently syringe, shade the trees in bright weather, and keep the house close for a time. Treated in this way a fair crop of fruit may be expected from them next year. When the fruits are gathered from later trees thin out those shoots not required for extension. This will assist in ripening the growths for next year's bearing.

FIGS.

The earliest varieties of Figs grown in pots have now matured their growth, and should be placed out of doors and be top-dressed or repotted if necessary. Remove some of the old soil and give a rich top-dressing of good fibrous loam, lime rubble, and bone-meal while the roots are still active. Any that require repotting should have all exhausted soil removed with a pointed stick, and be returned to the same sized pot, or given a size larger to increase the size of the tree. Remove any weak shoots from planted out trees. This will help to mature the young growths. Protect the fruits of late varieties of Brown Turkey and Brunswick from wasps and flies with hexagon netting.

GATHERING FRUIT.

Most of the early varieties of Apples and Pears have been gathered. Later varieties should receive

attention as they become ready. Fine dry days should be taken advantage of, as on no account must the fruit be gathered when damp. Every care should be taken not to bruise the fruits or gather them before they are ripe, or the colour and flavour will be impaired and late varieties will not keep so well. Keep the fruit room dark, and see that the ventilators are opened occasionally to carry off excessive moisture.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

LATE PEAS.

THIS has been a good season for this crop. An abundance of pods are still to be had. For late crops I give a few names of varieties that have done very well in this district. Few Peas can beat Walker's Perpetual Bearer, if the true sort has been procured, which seems a difficult matter, as two rows in this garden show a great difference in height and as croppers. Sutton's Perfection Marrowfat is a late sort that can be depended on. Veitch's Perfection is also a most reliable sort. All growers should have a few rows of Dr. MacLean, this variety doing well in a wet and sunless autumn. The chief points to ensure success with late crops of Peas are to see that the ground is rich, to sow thinly, and to have the rows wide apart. The plan of sowing 4 feet apart, as for early varieties, is not to be recommended. I prefer the rows 12 feet apart, where this is at all convenient, the spaces being cropped with other vegetables. At most of the horticultural shows I have seen this year the favourite variety has been The Gladstone. It is a sure prizetaker, and is a most valuable late sort, having large beautifully-shaped pods of splendid flavour.

GENERAL WORK.

Advantage should be taken of dry days to continue the earthing up of Celery, which is now making rapid growth. The tops should be tied with matting to allow the earthing up to be carried out in a proper manner. Should the weather continue dry water may again have to be applied. All Onions should now be lifted and laid on boards in the sun, store on a dry day, and in a cool airy place. This is a most suitable time for relaying Box and other edgings. If the operation is carried out about this date the ground becomes settled before frost sets in. Remove all loose and yellow leaves from Sea Kale that is intended for forcing, to allow the crowns to ripen before lifting. Inspect plots of Spring Cabbage, making good the blanks or weakly plants. Parsley plants should now be transferred to frames, choosing the late sowings for this work. A few boxes should also be filled; they are handy for placing in heat should a scarcity occur. Another sowing of Lettuce may yet be made, and also of Spinach, choosing a warm sunny position. Continue to add small quantities of soil to Leeks growing in trenches. Good liquid manure from the farmyard may also be given if extra large roots are required.

*Hopetoun House Gardens,
South Queensferry, N.B.*

THOMAS HAY.

ORCHIDS.

MASDEVALLIAS.

THE present time is the most favourable to give these Orchids a thorough inspection, selecting those that require rejuvenating or repotting, so that they may be attended to at once. Others will benefit by removing the surface material and adding fresh for the young roots that are now being emitted. Many failures to obtain the best results are brought about by the plants not being potted often enough. We find those that have been given fresh material at least every other year much superior to those that have been treated precisely the same with the one exception of not being potted so often. Plants that have deteriorated, and this is often noticeable in large specimens, should be carefully pulled apart and potted up separately, growths will then appear all round the plant. I prefer, if large plants are desired, to establish them in small pots and remake the specimen when they have become well rooted.

COMPOST AND POTTING.

The compost used should consist of fibrous peat two-fifths, chopped sphagnum two-fifths, and good leaf soil one-fifth, mixed well together with a fair quantity of small crocks and coarse sand. For the strong-growing, erect-flowering varieties ordinary pots are the most suitable, filling them for those that have good roots to the depth of one-third, and for the others the pots should be half filled with chopped rhizomes. Pot moderately firm, allowing enough room for a good surfacing of chopped sphagnum. When finished the base of the growths and the surface of the moss should be on a level with the rim of the pot.

AFTER TREATMENT.

Although many new roots are now being made they will require but very little water in any case. Those that have been repotted may be well watered once to settle the soil; then they should be allowed to become dry before more is given, and if the surface moss is slightly damped from time to time it will nearly suffice in maintaining enough moisture in the compost for their well-being. During this and next month damping between the pots is helpful, but overhead spraying should be stopped at once. They should still be kept well shaded; if given a position in a good Odontoglossum house that is well supplied with that most important yet sometimes neglected factor, fresh air, they will be found to respond freely to the treatment afforded. Thrip is often troublesome on them when the overhead spraying is discontinued, and, rather than subject the whole of the house to fumigating, I prefer spooging or dipping them in a safe insecticide.

MOST USEFUL SORTS.

Many are showy and useful decorative Orchids, and are certainly worthy of being better represented than they are at present in most collections. Perhaps those suited best for general work are *M. coccinea* (more often known under the name of *M. harr yana*), *M. veitchiana*, and the fine variety *M. v. grandiflora* (perhaps the most beautiful and useful of all). *M. Davisii*, *M. ignea*, *M. schroderiana*, *M. triangularis*, and many others all have claims to more than a passing attention.

Gatton Park Gardens, Reigate.

PLANTS THAT NEED CAREFUL HANDLING.

(Continued from page 198.)

COMPOSITÆ.

(10.) *CASSINIA ACULEATA*, R. Br.—This shrub is sometimes known as "Dogwood," and Dr. A. W. Finch Noyes, F.R.C.S., surgeon in charge of the skin department of the Melbourne and Alfred Hospitals, read a paper* before the Medical Society of Victoria on this plant, which is accredited as the cause of eczema.

Details are given of seven cases, several of which suffered only when the Dogwood was in flower, and the patient had come in contact with it by brushing through the scrub and other ways. The symptoms indicate that minute particles of some kind, such as pollen from the flowers, or irritating particles from the bark, get between the clothing and the skin, and where there are loose folds of clothing in contact with parts of the skin inflammation is often produced. The eruption is often scaly, with great irritation, and a feeling described in some cases as if fire were running through the part. In one case a resident of Gippsland was driven from the district twelve years ago, and six months ago returned. He had a second attack of the eruption, which was relieved when he left the district. He determined to live down his susceptibility, and went back, but returned a few weeks ago with an eruption similar to that in previous attacks.

(11.) *Pyrethrum* (*Chrysanthemum*) *Parthenium*, Sm. "Feather Few."—The late Rev. H. E. Thomson, of Murrumburrah, N.S.W., could never

* *Chemist and Druggist of Australasia*, August, 1899, page 240.

tolerate this plant, which always produced an eczematous swelling on his face. He was fond of gardening, and proximity to this plant always distressed him. He tried to resist the effects, and finally had to remove all such plants from his garden.

PRIMULACEÆ.

(12.) *Primula obconica*, Hance.—Dr. S. A. L. Swan records* two cases which came under his notice in Ireland in which the symptoms produced by handling this plant resembled those of acute eczema or erysipelas. The effect of this plant on human beings is now well recognised by gardeners, and references to it in horticultural literature are frequent. For example, *Gardeners' Chronicle*, April 9, 1892, page 469.

At the same time some people are not affected by it. This is the case, however, with most plants which are irritant.

It is alleged that Dr. Riehl of Vienna has ascertained that the irritation is caused by the tiny hairs on the leaves and stalks.—*Gardeners' Chronicle*, May 4, 1895, page 558.

(13.) *Primula sinensis*, Sabine.—Eczema of the hands and face has been caused through handling this Primrose. It appears to be less virulent than *P. obconica*.—*Gardeners' Chronicle*, January 12, 1895, page 47; January 26, 1895, page 116.

EUPHORBACEÆ.

(14.) *Excecaria Agallocha*, Linn.

(15.) *Excecaria parviflora*, Muell. Arg.

These two yield an acrid juice which is more or less volatile, and which, if it gets into the eyes, will produce temporary loss of sight and other local irritation.

(To be continued.)

SOCIETIES.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE usual monthly meeting of this association was held in Dowell's Rooms, George Street, Edinburgh, on the evening of Tuesday, the 6th inst. There was a large attendance, and the chair was occupied by Mr. J. W. McHattie, superintendent of the City Parks and president of the association. The paper for the evening was read by Mr. John B. Cumming, Grantully Castle Gardens, Perthshire, its subject being the important one of "The Arrangement of Cut Flowers for House Decoration." The paper was one of the best of the session, the subject being treated in an attractive and exhaustive manner, so that its appearance in the "Transactions" of the association may well be awaited with interest by those not privileged to be present. Nothing of importance was omitted, and the treatment was such that even the most experienced could not fail to profit by it. The lecturer referred to the ineffective use frequently made of the material employed and the artistic arrangements often produced by even the most graceful flowers and foliage. He deprecated the massing together of a number of different flowers without any attempt at symmetry or harmony, and pointed out the various principles which underlie the floral art of Japan as suggestive of some, at least, of the proper methods. He also showed how useful it was to be acquainted with the duration of the flowers employed in house decoration, and with the proper stage at which they ought to be cut. Many other practical questions were also discussed, and the whole question of arrangement fully considered. The discussion which followed was an interesting one, and Mr. Cumming was heartily thanked for his valuable paper. Several exhibits were on the table.

ROYAL CALEDONIAN SOCIETY'S SHOW.

THE great autumn meeting of this society was held as usual in the Waverley Market, Edinburgh, under most favourable conditions, on the 14th and 15th inst., the entries being large, and the weather all that could be desired, ensuring a very satisfactory response from the public, who visited the exhibition in great numbers. Lady Linnithgow opened the exhibition on the first day, being accompanied to the platform by Lady Tweeddale and Mr. and Mrs. Usher. Lord Balfour of Burleigh, president of the society, was in the chair, supported by a large body of horticulturists.

FRUIT.

The most interesting feature of the show was the Grape class for eight bunches, for which Mr. Massie's Challenge Cup, value fifty guineas, with a gold medal and £15 was the first prize. The competition between the first and second collections was more than usually keen, the former from Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, securing 57 points, and the latter from Messrs. Buchanan, Fort, Viueyard, Kippen, 56½ points, so that the cup was lost and won by the extremely narrow margin of half a point. Mr. Goodacre's Grapes were less bulky than Messrs. Buchanan's, his strongest bunches being the fine Muscat of Alexandria, Scottish examples all through the

show, including those of his antagonist, being far from ripe, while the Elvaston ones were about their best. The third prize was secured by Mr. Beisant, Castle Huntly. The cup Grapes, it may be added, were, besides Muscat of Alexandria, the Black Hamburg, Madresfield Court, and Gros Maroc.

The decorated dinner-table brought two competitors only, Mr. Goodacre being first for fruit with 115 points, second for flowers with 23 points, and Mr. Kidd, gardener to Lord Elphinstone, Carberry Tower, second for fruit with 107½ points and first for flowers with 26 points.

For a collection of ten dishes of fruit, confined to Scottish growers, Mr. Kirk, gardener to J. Thomson Paton, Esq., Norwood Park, was easily first, the Grapes being particularly fine.

In the class for twelve dishes of orchard house fruits Mr. Goodacre was first, with large and fine samples of Pears, Apples, Peaches, &c.

In the class for four bunches of Grapes Mr. Kidd was first; and in the single variety classes there was keen competition, though the quality as a rule was considered by competent observers to have been, if anything, inferior to that of last year. A new Grape shown by Mr. Kirk, named *Directeur Tisserand*, secured first ticket in the class for novelties, and, as shown, appeared a very handsome acquisition to the black section.

In the hardy fruit section there was a notable display of high-class produce in Apples and Pears alone, the increase of entries over last year, when these were shown in reduced numbers, amounted to no less than 204. In Apples especially, quality was good, the bulk of the prizes going to growers in Sussex, Surrey, Hereford, &c.

PLANTS.

In the section devoted to plants there was little calling for special mention, the specimens, though well grown, being somewhat smaller in size than is usual with exhibition plants in the South. Worth mention, however, was the class for a group of miscellaneous plants, arranged on the floor of the building in a circle 18 feet in diameter, the first prize group from Mr. Hughes, Kingsmeadows, Peebles, being furnished with capitally-grown plants, particularly well arranged.

CUT FLOWERS.

Cut flowers showed some improvement over last year, there being an increase in entries and also an improvement in quality. Of Sweet Peas alone there was an enormous quantity, the size and colour of the blooms calling forth the admiration of visitors from the South. Mr. Duncan, Forth, Duns, secured first in the twelve bunch class, Mr. Malcolm, Duns, being a close second; and for six bunches Mr. Gorenlock, Galashiels, was first, Mr. Duncan being second.

Of Carnations and Picotees, which were all shown in vases, there was a most extensive display, Mr. Innes, Hawick, beating all competitors in the three classes.

Specially beautiful, too, were the Roses, which formed one of the chief attractions of the show. The blooms, as could hardly be expected, were not large, but they were perfect in form and of clear and bright colouration. Messrs. Black, Kinglassie, Dalgarro, Arbroath; Whyte, Helensburgh; and Brydon, Innerleithen, being the chief contributors. The last named staged, too, splendid groups of herbaceous plants.

Of vegetables there was a grand display of single dishes in great variety. The tables of vegetables, however, were only two, Mr. Hooper, Tulliebolton House, Perth, being easily first with a varied and high-class collection.

There was a small section for cut flowers devoted to nurseriesmen. In this Dahlias bulked largely, but Roses were undoubtedly the best and most attractive feature. For thirty-six blooms Messrs. J. Cocker and Sons, Aberdeen, were first with fresh and attractive blooms; Mr. Hugh Dickson, Belfast, second.

For eighteen blooms Messrs. D. and W. Croll, Dundee, secured first; Messrs. Dicksons and Co., Craigmillar, second. The best twelve blooms were staged by Messrs. W. and R. Ferguson, Dunfermline, while Messrs. Croll, with lovely blooms, were first for twenty-four Teas.

There were also well-filled classes for various coloured Roses, Hugh Dickson (crimson), Mrs. J. Laing (pink), and Frau Karl Druschki being the best Roses in these classes. Messrs. Cocker and Son secured first for twelve vases of Roses and for a collection in which Dorothy Perkins was conspicuously fine.

TRADE EXHIBITS.

These were numerous and generally fine. Large groups of plants were contributed by Messrs. Laird and Sons, Limited, Pinkhill; Messrs. Methven and Sons, Warriston; and Messrs. Cunningham, Fraser and Co., Comely Bank. An interesting collection of Apple trees in pots from Messrs. Storrie and Storrie, Dundee, was much admired. In cut flowers Mr. Eckford, Wem, contributed Sweet Peas; Mr. Forbes, Hawick, florist's flowers, among which Carnations, Phloxes, and Pentstemons were extremely fine. Messrs. Dobbie and Co., Rothsay, staged a wonderful display of the best Cactus Dahlias with other flowers; and Messrs. Cunningham, Fraser and Co. herbaceous flowers, *Kniphofia Rufa* and others being splendid. Messrs. Cocker also set up a large stand of herbaceous material along with Roses, while Messrs. Grieve and Sons, Pitrig, had fine Chrysanthemums; and Mr. Lister, Rothsay, Violas. The King's Acre Nursery Company showed a large collection of well-finished hardy fruits. Several exhibits were certificated by the committees of the society, and all the above exhibits were awarded medals.

LECTURE.

Under the auspices of this society a lecture on "Potato Problems and Developments" was delivered in the hall of the Young Men's Christian Association, St. Andrew Street, Edinburgh, on the 14th inst. There was a good attendance, presided over by Mr. J. W. McHattie, city gardener. The lecturer was Mr. Walter P. Wright, secretary of the National Potato Society, who was briefly introduced by the chairman. Mr. Wright gave a very interesting lecture, commencing at the outset the objects of the National Potato Society, and asking the support of his hearers to the movement. He next

dealt with the importance of the Potato crop to the community, pointing out that it was estimated that the total produce of the tuber of the three kingdoms, estimated at a value of £3 per ton, amounted to no less than £20,000,000 per annum. He believed that the demand for Potatoes would continue to increase, and considered that new uses for the tubers might be found. The appointment of the committee on duty-free alcohol for manufacturing purposes was cited as affording reasonable hope for opening out a new use for the Potato in the making of spirit for such purposes. The growing of seed Potatoes was also referred to, and Mr. Wright observed that there was surely here an opening for horticulturists, who had left this trade largely in the hands of the farmers. Experiments with manures were also spoken of, Mr. Wright's own experience being in favour of cow manure, with, in some soils, the addition of some superphosphate and kainit, or sulphate of potash and steamed bone flour. His ideal manure was cow dung, with a light dressing of kainit. Diseases, change of seed, the greater stamina of early varieties, and several other questions were fully discussed. Mr. Wright concluding a very interesting lecture by giving an account of the behaviour of a number of varieties in his own garden and trial grounds. A most interesting discussion took place at the close, this being taken part in by the chairman and Messrs. Davie, Smith, Scarlett, Taylor, Varlow, Niven, McLaren, and Laird. On the motion of Mr. P. Murray Thomson, seconded by Mr. Blanshard, a hearty vote of thanks was accorded to Mr. Wright. A suggestion that the lecture should be printed and issued by the Royal Caledonian Society, made by Mr. Davie of Haddington, was greatly approved of by the audience.

LONDON DAHLIA UNION.

THIS association held an excellent show at Earl's Court on Thursday and Friday of last week. Many beautiful flowers were shown in the competitive classes, and, in addition, there were some splendid trade displays. Certificates of merit were granted to several new varieties, particulars of which will be found below.

For the best display of Cactus Dahlias, arranged with foliage of any kind, Mr. Seale, Vine Nurseries, Sevenoaks, won the first prize with a very handsome display, the flowers being arranged in Bamboo stands and vases. Messrs. Cheal and Sons, Crawley, were second.

For six vases of distinct Cactus Dahlias, Mr. Mortimer, Farnham, Surrey, was first with lovely varieties, of which we give the names, as they may be taken to be six of the best: Winsome, creamy white; Manxman, glowing red; Clara G. Stredwick, apricot-buff; Mrs. H. L. Brousson, a similar but much paler flower; Mrs. John Barker, rosy red; and Percy Mortimer, yellow centre, outside petals rose. Messrs. Cheal and Sons were second.

For three vases of Cactus Dahlias, distinct (new varieties of last year), Mr. Seale was first, showing Osprey, a rich yellow flower, splashed with bright red; Rainbow, a lovely light rose, with paler centre; and Mavis, apricot-buff. Messrs. Keynes, Williams, and Co., Salisbury, were second.

CACTUS DAHLIAS.

Twelve varieties in bunches of six blooms: First, Messrs. J. Stredwick and Son, St. Leonards-on-Sea, with a very beautiful lot. Lady Colin Campbell is a rich yellow; H. F. Robertson, lemon-yellow; Columbia, bright red, the petals tipped cream, all very beautiful. Messrs. J. Cheal and Sons were second. Rainbow, lilac-rose, with paler centre, was very beautiful. Third, Mr. Stredwick, Westfield, Woking.

Twelve blooms, distinct: First, Mr. Seale, Sevenoaks. Lord of the Manor, bright red; Slough Rival, ruby-red; and Mrs. Mawley, light yellow, were of the best. Second, Mr. Baxter, Woking; third, Mr. Turner, Slough.

Twenty-four blooms of Cactus Dahlias: First, Messrs. J. Stredwick and Son, St. Leonards. J. B. Riding, Thomas Parkin, and Pearl were very fine. Second, Mr. S. Mortimer, Farnham, Surrey, with some lovely blooms.

Six bunches of Pompon Cactus Dahlias: First, Mr. John Walker, Thame, with Freedom (dark red), Coronation (bright red), Purple Gem, and others; second, Mr. Seale.

Four varieties: First, L. McKenna, Esq., Waltham, St. Lawrence. Violetta was very showy; second, Mr. H. A. Needs, Horsell, Woking. J. Weir Fife (velvety purple) was a very fine variety.

Twenty-four blooms of show varieties: First, Mr. J. Walker, Thame; second, Mr. S. Mortimer; third, Messrs. Keynes, Williams, and Co.

Twelve blooms of show Dahlias: First, Mr. E. West, jun., Fries, Henley; second, Mr. Seale; third, Mr. J. R. Tranter, Henley. Mr. West was also first for twelve blooms in the amateurs' classes.

The first prize (amateurs) for nine varieties, in bunches of three blooms (together with Hobbies' Challenge Cup), was won by Mr. W. Peters, gardener to Vice-Admiral Sir Lewis Beaumont, Baldston, St. Leonards. Phineas (large bright deep red) was perhaps the best bloom; L. McKenna, Esq., Waltham St. Lawrence, Berks, was second; third, Mr. W. G. Rouse, gardener to F. C. Greville-Smith, Esq., Hounslow.

Six blooms of Cactus varieties (amateurs): First, Mr. W. Lockyer, the Lodge Gardens, New Barnet. Mrs. D. B. Crane (white) was excellent; second, the Rev. S. Spencer Pearce, Combe Vicarage, Woodstock.

Twelve Cactus blooms (amateurs): First, Mr. H. A. Needs, Horsell, with some fine flowers, Etna (mauve with a tinge of buff) being beautiful; second, Mr. G. Davidson, Thornton Heath.

Six blooms of one Cactus variety: First, Messrs. Stredwick and Son, with J. B. Riding, a very beautiful lot.

Three vases of Cactus Dahlias: First, Mr. Seale; second, Mr. H. A. Needs.

One of the most effective vases in the show was that shown by Mr. E. Mawley, an orange-red variety with some sprays of a dark bronze-leaved shrub. Mr. Needs won the first prize in this class, however, with a vase of a light coloured variety. Mr. A. Taylor, East Finchley, had the best vase of singles.

Six varieties of Pompons in bunches: First, Mr. H. Brown, Luton. Phoebe, orange-red; Nerissa, rich rose; and

* *Lancet*, April 25, 1891, page 960; *Pharmaceutical Journal*, May 2, 1891, page 981.

Darkest of All were of the best. Second, Mr. Pagram, Weybridge; third, Mr. W. Peters.

Twelve varieties of Poppoms in bunches: First, Mr. Charles Turner, Slough, with a lovely lot. Edna, rich bright yellow; Fabio, orange-red; Queen of Whites, and Montagne Wolten, crimson, were of the best. Second, Mr. Seale; third, Messrs. Burrell, Cambridge.

Twelve varieties of singles in bunches: First, Messrs. Cheal and Sons, Crawley. Wm. Parrott, scarlet and white; Snowdrop, white, yellow centre; and Miss Molland, deep red, were very beautiful. Second, Mr. Seale, Sevenoaks.

Six varieties of singles in bunches: First, Mr. E. West, jun., Erieth, Henley. Formosa, rich red, and Fascination, lilac and yellow, were very attractive. Second, Mr. E. Mawley. Miss Roberts, rich yellow, was very fine.

NON-COMPETITIVE EXHIBITS.

Messrs. R. H. Spooner and Sons, Hounslow, exhibited some excellent hardy fruit (gold medal); Messrs. Baker's, Wolverhampton, made a striking display with Dahlias in bewildering variety (gold medal). Messrs. T. S. Ware obtained a gold medal for an exhibit of Dahlias; and so did Hobbies, Limited, Dereham, Norfolk, both being excellent. Messrs. Burrell and Co., Cambridge, were awarded a gold medal for a splendid lot of Gladioli; Mr. West, Brentwood, for Dahlias; and Messrs. Cammell and Sons, Swanley, for Dahlias. Mr. Gwillim, New Eltham, showed tuberous Begonia blooms (gold medal); Mr. E. F. Such, Mordenhead, sent hardy flowers (silver-gilt medal); and Mr. Williams, Ealing, showed table decorations.

NEW DAHLIAS—CACTUS VARIETIES.

Crepusculum.—A pretty buff and yellow flower, the latter colour more pronounced at the centre. From Messrs. Burrell and Co., Cambridge.

Mont Blanc.—White, good form; a very full flower. From Mr. Walker, Thame.

Autumn.—Buff, lemon-yellow prevailing towards the centre.

Fairy.—A white variety, with thin quilled petals, cream in the centre.

J. B. Riding.—Orange-red, with yellow centre. These three were from Messrs. Stredwick and Son, St. Leonards.

Cockatoo.—Lemon-yellow, fading to white at the edges; a beautiful flower. From Messrs. Keynes, Williams, and Co., Salisbury.

Harbour Lights.—A rather small pale yellow flower of good form. From Hobbies, Limited, Dereham.

POMPON VARIETIES.

Wilfred.—Deep lilac-rose.

Edina.—Rich bright yellow; very beautiful. Both from Mr. C. Turner, Slough.

Little Mary.—Very dark red. From Mr. Seale, Sevenoaks.

SINGLE VARIETY.

Mikado.—A striking variety, with red centre and yellow outer petals.

SHOW VARIETY.

Mrs. Hobbs.—A good white sort. From Mr. T. Hobbs, Downend, Bristol.

Other varieties that obtained certificates of merit, in addition to those described above, were Cactus varieties W. E. Dickson, Crayfish (Shoemith), Alexander (Mortimer), Helen Stephens (Hobbies, Limited), and Pompon Cactus Purple Gem (Walker).

ROYAL HORTICULTURAL SOCIETY.

THE meeting in the new hall last Tuesday was exceptionally interesting. In addition to the fortnightly exhibition of the Royal Horticultural Society, the National Rose Society held their first autumn Rose show, particulars of which are given elsewhere. Hardy flowers, as Dahlias, Asters, Begonias, Phloxes, Lilies, Sunflowers, &c., were largely shown; there were several new Orchids, new fruits, and flowers, as well as numerous groups of fruit trees and fruits and Orchids.

ORCHID COMMITTEE.

Present: Mr. Harry J. Veitch (chairman), Baron Sir Henry Schroder, Bart., Messrs. James O'Brien, de B. Crawshaw, H. M. Pollett, A. A. McBean, J. Wilson Potter, W. H. Young, W. Boxall, H. A. Tracy, G. F. Moore, F. W. Ashton, W. A. Binney, Thomas Bond, R. G. Thwaites, Jeremiah Colman, Francis Wellesley, Walter Cobb, H. Little, F. J. Thorne, J. Charlesworth, and H. Ballantine.

Messrs. Sander and Sons, St. Albans, exhibited some showy Orchids in their group. *Zygopetalum dayanum*, with creamy white sepals and petals tipped with crimson, and *Cattleya calumata* (intermedia × Acklandiae), light rose sepals and petals spotted with crimson and rich purple lip, were striking plants. *Lelia Pucavia*, *Cattleya Maroni*, *Miltonia bleuana*, *Cypripedium insigne* (yellow), *C. Miss Annie Measures*, *C. Hayetti*, and *C. Prince Humbert* (mastersianum × niveum) were other good things included. Silver Flora medal.

Cattleya intermedia-gigas, raised from seed sown June 26, 1901, was shown by Jeremiah Colman, Esq., Gatton Park, Reigate (gardener, Mr. Bond).

H. S. Goodson, Esq., 85, West Hill, Putney, S.W. (gardener, Mr. G. E. Day), sent a group of Orchids that was bright with *Cattleyas*, *Lelios-Cattleyas*, *Lycastes*, *Oncidiums*, &c. The white *Lycaste Skinneri* was very beautiful, and so was the variety *delicata*. *Cypripediums* were well and numerous represented. Silver Banksian medal.

The Hon. Walter Rothschild, Tring Park, Tring (gardener, Mr. Dye), sent a small group of *Massevalias* that included some most interesting species. The rare *Angraecum infundibulare* was in this exhibit, and obtained a cultural commendation. *Cattleya aurea* was finely shown, and so were several *Lelios-Cattleyas*. *Angraecum rothschildianum*, which obtained an award of merit, is described under new Orchids. Silver Banksian medal.

The showy group from Messrs. Hugh Low and Co., Enfield, contained *Cattleya Minucia*, *C. speciosissima striata*, *C. bicolor*, *C. dowiana*, *C. gaskelliana*, *Odontoglossum grande*, *Oncidium varicosum*, *Dendrobium Phalenopsis*, and *D.*

formosum giganteum, all of which helped to make a very bright display. Vote of thanks.

In the group shown by Messrs. James Veitch and Sons, Limited, Chelsea, were many good hybrid *Lelias*, *Cattleyas*, and *Lelios-Cattleyas*. *L. C. diglypha-gigas*, *L. C. Erysa*, *L. C. callistoglossa ignescens*, *L. C. bleichdeyensis*, *L. C. Hermonia*, *L. C. welliana*, *L. C. Zephyra*, *Lelia Mrs. Gratrix*, *L. splendens*, *L. Pucavia*, *Cattleya Vasco*, and *C. patina* were all handsome flowers of beautiful shades of colour. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, showed some beautiful flowers in their group. One was given a first-class certificate, and two received awards of merit. But, besides these, this exhibit was full of good things, e.g., *Cattleya Iris aureo-marginata* (*C. bicolor* × *C. aurea*), *C. Iris*, *Brasso-Cattleya Warneri-diglypha*, *L. C. haroldiana* (sepals and petals deep rose and yellow, lip purple), and *L. C. haroldiana* var. *aurifera* (with sulphur-yellow sepals and petals and rich purple lip). *Odontoglossum grande* was very good; so, too, was *Cypripedium Charlesworthii*. *Brasso-Cattleya M. Charles Maron* is a handsome flower of remarkable size, mauve, except for the yellow throat. Those flowers that were certificated are described under "New Orchids." Silver-gilt Flora medal.

Mr. James Cypher, Cheltenham, exhibited several plants of *Burlingtonia caudata*, bearing racemes of small white flowers, with a blotch of yellow on the lip. Cultural commendation. Vote of thanks.

Cattleya Lady Ingram Westfield variety, most delightfully scented, with bluish sepals and petals, purple lip, and rich yellow throat (first-class certificate, 1902), was shown by F. Wellesley, Esq., Westfield, Woking.

NEW ORCHIDS.

Odontoglossum crispum xanthotes Charlesworth's variety. — A very beautiful flower, white, and fairly heavily spotted with amber-yellow on the sepals and less so on the petals. The lip is long, with frilled edges, and is white with amber blotches, while that part beneath the column is a lighter shade of yellow. The form of the flower is perfect. From Messrs. Charlesworth and Co., Heaton, Bradford. First-class certificate.

Cattleya Iris var. *Prince of Piedmont*. — *Cattleya bicolor* and *C. aurea* are the parents of this striking hybrid, whose flower is large, with greenish brown sepals and petals and rich crimson lip, minutely dotted with white. The lip shows finely against the dark sepals and petals. From Messrs. Charlesworth and Co., Bradford. Award of merit.

Cattleya Iris aurifera. — A very handsome flower with broad rich greenish yellow sepals and petals and purple lip. The parents are *C. bicolor* and *C. aurea*. From Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

Angraecum pycnostachyum. — An attractive small-flowered Angraecum. The blooms, which have white sepals and petals tinged with green, and a rich green lip with broad white margin, are produced on a short raceme. The plant exhibited carried a raceme about 6 inches long, bearing four flowers. From the Hon. Walter Rothschild, Tring Park. Award of merit.

Laelio-Cattleya eximia Sander's var. — A large and very handsome flower with lilac-rose sepals and petals, slightly drooping, and broadly expanded rich purple lip with deeper purple veins; the throat is a lighter shade of purple with white veining. The parents were *Cattleya Warneri* and *Lelia purpurata*. From Messrs. Sander and Sons. Award of merit.

Laelio-Cattleya Constance Wigan. — A very pretty flower of medium size. The sepals and petals are ochre yellow, the lip cream suffused with purple. The throat is yellow with purplish lines. This hybrid resulted by the intercrossing of *Lelia xanthina* and *Cattleya rex*. From Sir Frederick Wigan, Bart. (Orchid grower, Mr. Young). Award of merit.

FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. H. Somers Rivers, A. H. Pearson, W. Poupard, George Wythes, J. Jacques, W. H. Divers, G. Norman, G. Reynolds, F. Q. Lane, P. C. M. Veitch, E. Beckett, William Fyfe, George Kelf, Alex. Dean, William Pope, James H. Veitch, Owen Thomas, Henry Parr, H. Markham, S. Mortimer, and J. Cheal.

From Lord Alldenham's gardens at Elstree (gardener, Mr. E. Beckett) there was shown a very fine collection of vegetables, set up in a most attractive fashion. At the back were heads of Cauliflower, Onions, Globe Artichokes, Savoy, &c., embedded in mounds of Parsley, and Parsley formed the groundwork to the whole exhibit, which included *Solanum esculentum* (Egg Plant), Potato Yeoman (white, splashed with purple), Tomato Ryecroft Exhibition, Tomato Golden Nugget, Tomato Peach Blow, Carter's Onions Record and Ailsa Craig, Potato Up-to-Date (very fine), as well as the finest specimens one could wish to see of Leeks, Celery, Vegetable Marrows, Runner Beans, Beet, Tomatoes, Potatoes in great variety, and other vegetables. It was a splendid display of vegetables, that denoted cultural excellence and attractive arrangement. Gold medal.

Messrs. Barr and Sons, King Street, Covent Garden, showed a collection of Kale and Cabbage. Of Kales there were *Exquisite*, *Dwarf Purple*, *Improved Hearting*, *Barr's Paragon*, and *Asparagus Kale*, and of Cabbages we noted *Barr's Little Queen*, *Barr's Best of All*, *Autumn Exhibition*, and *Very Dwarf Savoy*.

Mr. W. H. Divers, head gardener to the Duke of Rutland, Belvoir Castle, Grantham, exhibited an interesting collection of Plums in numerous varieties, chiefly from wall trees. Among the best dishes were *Archduke*, *Golden Transparent*, *Mazum Bonur*, *Diamond*, *Reine Claude de Bavay*, *Nectarine Plum* (orchard tree), *Rivers' Late Orange*, as well as several sorts of Damsons. Silver Banksian medal.

Messrs. James Veitch and Sons, Limited, Chelsea, exhibited some pot Vines of the varieties *Gros Maroc*, *Madresfield Court*, *Blackland Sweetwater*, *Alicante*, *Black Hamburgh*, and *Foster's Seedling* that were bearing splendidly. All the canes were struck from "eyes" early in 1903. Silver Knightian medal.

Messrs. J. Peed and Sons, West Norwood, were awarded a silver Knightian medal for an excellent display of Apples and Pears. Good size and rich colour were shown by most of the varieties exhibited, which contributed to make a very satisfactory display.

Messrs. Harrison and Sons, Leicester, exhibited a collection of Tomatoes, for which they were awarded a bronze Banksian medal.

There were several small exhibits of Tomatoes, Melons, Apples, &c., but the only awards made were a cultural commendation for Potato Eldorado to Mr. Charles Blick, Hayes, Kent, and a similar award for Celery Aldenham Pink Perfection to Mr. E. Beckett, Aldenham, Elstree.

NEW FRUITS.

Apple the Rev. W. Wilks. — Peasgood's Nonsuch and Ribston Pippin are the parents of this new Apple, which is large and handsome. The colour is pale yellow or greenish yellow, faintly speckled on the sunny side with red. It is more conical in shape than Peasgood's Nonsuch. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

Crab Veitch's Scarlet. — This is the result of a cross between the Red Siberian Crab and Apple King of the Pippins. The fruit is of medium size and rich crimson colouring. From Messrs. James Veitch. Award of merit.

Strawberry Elythrae Perpetual. — This is a perpetual fruiting variety obtained by crossing St. Antoine de Padoue with a Pine-flavoured Strawberry. The fruits are larger than those of St. Antoine, and, while being of good flavour, are freely produced at this time of year. From Miss Alice de Rothschild, Elythrae. Award of merit.

Crab Frettingham's Victoria. — An ornamental Crab of moderate size, and bright scarlet-red colouring. From Mr. W. H. Frettingham, Beeston Nurseries, Notts. Award of merit.

FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), Messrs. H. B. May, George Nicholson, James Walker, E. Molyneux, G. Reuthe, J. W. Barr, Charles E. Pearson, R. Harper Pearson, William Howe, C. R. Fielder, Charles Dixon, Charles Jeffries, R. W. Wallace, H. J. Cutbush, William Cutbush, W. J. James, J. Jennings, Charles Blick, Charles T. Drury, R. Dean, J. Green, J. F. McLeod, C. J. Salter, and the Rev. F. Page Roberts.

Hardy autumn flowers were well shown, and several leading growers staged large collections. That from Mr. M. Prichard, Christchurch, Hants, included masses of *Aster amellus*, *A. acris*, and others, in company with *Phygelius capensis*, *Tiger Lilies*, *Rudbeckia hirta* (very fine), handsome trails of *Tropaeolum speciosum*, rich in colour and of verdant growth. Many kinds of *Kniphofias* were shown in a group. *K. corallina*, *K. Macowanii*, and others arranged amid their grassy leafage were very striking. *Solidago Buckleyi*, a very dwarf plant, is quite good. *Phloxes* and *Pyrethrums* were also represented. Silver Banksian medal.

Messrs. Barr and Sons, Covent Garden, contributed *Kniphofias*, *Japan Anemones*, *Sternbergia lutea*, and *Cyclamen neapolitanum* in boxes, *Asters* of the *Amellus* and *acris* sections, *Gaillardias*, *Origanum hyridum*, a good plant with rose-coloured flowers, *Colchicums* in variety, *Sagittaria japonica plena*, *Gladioli*, *Tigridia grandiflora alba*, and many more. *Grasses* and *Eulalias* were also freely employed in the arrangement. Silver Banksian medal.

Mr. H. B. May, Edmonton, showed *Bouvardias* and *Ferns*, together with *Roses*.

Messrs. Cammell and Sons, Swanley, staged a magnificent lot of Cactus Dahlias, the flowers and not less the excellent manner of arrangement commanding attention. The good arrangement was much enhanced by a rather free use of sprays of *Kochiascoparia*. We cannot pretend to give a list of sorts, but of recent ones we select *Sweet Nell*, rose-pink, white centre; *Ibis*, orange-scarlet; *Mrs. J. Mace*, delicate pink; and *Fred Cobold*, crimson. Of large decorative sorts, *Souv. de G. Donjon*, crimson flowers 9 inches across; *Beauty of Kent*, maroon, white tips; *Mme. Van den Dael*, a huge pink; and *Perle de la Tête d'Or*, a pure white kind, were very fine. Silver-gilt Banksian medal.

Another fine lot of Dahlias was from Messrs. W. Cutbush and Sons, Highgate, who arranged stands of this flower with the best effect. We noted *Miss Grace Cook*, deep rose pink; *Cornucopia*, orange-scarlet; *Sailor Prince*, crimson velvet; *Florence Stredwick*, white; *Mabel Needs*, dazzling crimson with finely fluted florets; *Britannia*, buff; *Felix Calvert*, orange-buff; and *H. F. Robertson*, a fine self yellow and a novelty of 1904. Silver Flora medal.

Another fine lot of Dahlias was that from Hobbies, Limited, Dereham, and here again the excellence of the flowers and the arrangement call for special note. We take *Florence Stredwick*, white; *Conrad*, orange; *Minnie West*, white and cream; *Charm*, a very remarkable flower in which pale orange mingles with scarlet, with buff on the reverse and white tips; *Heleo Stephens*, a pretty yellow and a perfect flower; *Effective*, one of the best garden Cactus forms; and *Harbour Lights*, a unique flower with pale orange ground, lightened with shadings of mahogany, and tipped a deeper hue. Silver Flora medal.

Dahlias, too, were in fine form from Mr. J. T. West, Brentwood, and here we noted Cactus with Pompons in rich and varied array. Of the Pompons we take *Little Bugler*, deep rose; *Darkest of All*; *Dewdrop*, lilac and white; *Sunshine*; and *Ideal*, yellow. Some capital blooms of the show kinds were also staged on boards. Silver Flora medal.

The *Roses* from Messrs. George Jackman, Woking, were a very pretty lot, a large collection being staged. *Papa Gontier* was very charming, while many of the single blooms set in tubes were also of fine quality.

Messrs. Wells and Co., Redhill, Surrey, contributed a good lot of early *Chrysanthemums*, among which were *Roi des Blancs*, *The Champion*, a rich golden yellow; *Nellie*, yellow; *Orange Pet*, and *Gertie*, orange. Large blooms of *Mme. Von André*, soft yellow, and the Hon. Mrs. Ackland, golden yellow, were also in this group.

Mr. J. Walker, Thame, Oxon, had a few Cactus Dahlias in variety.

THE GARDEN

No. 1715.—VOL. LXVI.

[OCTOBER 1, 1904.]

BULB FARMING IN IRELAND.

WE may safely assert that no finer or better bulbs of Narcissus, Tulip, Snowdrop, Crocus, Iris, or even of Gladiolus and Holland's own speciality, the Hyacinth, are produced anywhere than the best of those grown on Irish soil." So wrote an expert in the *Irish Times* some months ago. Such a testimony as this to the suitability of Ireland as a bulb-growing country is convincing, and, moreover, practical evidence in support of this statement is not wanting. For some years past bulbs have been grown in several districts, and the production has been so satisfactory as to justify its extension. We are not sufficiently optimistic to believe that Ireland either can or will ever become a second Holland as regards bulb culture, for all districts are not suitable for the purpose. "Holland in Ireland" is now a familiar term, but its familiarity has to some extent given rise to erroneous impressions concerning Ireland as a bulb-producing country. Messrs. Hogg and Robertson aptly summarise matters thus: "There are undoubtedly isolated spots in Ireland where bulb growing can be made a successful industry; but on the other hand there is much too great a tendency to generalise on the subject and to describe Ireland as a sort of bulb-growing Eldorado." So far as we know bulb growing to any extent in Ireland is carried on by Messrs. Hogg and Robertson at their farms at Rush, County Dublin; Mr. W. Baylor Hartland at Ard Cairn, Cork; Miss Currey at Lismore, County Waterford; and Messrs. Alex. Dickson and Sons, Newtownards, County Down. Although the number of growers is so small, the results obtained by them would seem to justify bulb culture on a larger scale. Needless to say, it will never be possible to grow enough bulbs in Ireland to make us independent of Dutch-grown supplies, but that is no reason why the industry should not be encouraged to develop as long as it can be developed profitably. It could not fail to increase the value of the land and bring prosperity to the inhabitants. Even on Messrs. Hogg and Robertson's farm of some 30 acres, between eighty and 100 men are employed at good wages, and it is the same on the other farms mentioned. Congenial and profitable labour tends to increase the self-respect and promote the contentment of the working man, and so bulb farming in Ireland, if carried to its

limits, might ameliorate to some extent the conditions of life and labour there.

To get suitable land it has to be taken in patches of about one to three acres each. The essentials to successful bulb culture are subsoil moisture and a mild and genial spring; these may be said to be ideal both for the development of the bulb and the flower. Writing in *THE GARDEN* some time ago about the Rush bulb farm, a correspondent in Ireland stated: "Though I have seen Tulips in Holland and in England, I never saw them happier than upon this wind-swept shore. The soil is mainly sand, which has for ages been manured with seaweed from the adjacent shore. It is deep and easily worked in nearly all weathers, and is supplied with moisture from below in much the same way as are the bulb and other gardens of the Dutch and Belgians. This sunny strip of land is said to have the lowest rainfall in Ireland, for which the subterranean moisture makes amends. I never, even in Holland, saw foliage so clean, strong, and healthy or flowers so fresh and splendid in form and colour. Now that the fact is accomplished, one wonders why bulb culture was not tried here long ago." Messrs. Hogg and Robertson grow a variety of bulbs, *e.g.*, Daffodils, Tulips, Irises, Crocuses, and Anemones, all of which thrive well in the cool, moist, sandy soil. On the bulb farm near Cork Mr. Hartland grows chiefly choice May-flowering Tulips and Daffodils, while in County Waterford Miss Currey restricts her enterprise to Daffodils, and at Newtownards Tulips and Daffodils are the chief bulbs grown. Many beautiful Daffodils and Tulips have been raised by Mr. Hartland, who has long cultivated bulbs at Ard Cairn. Bulb culture in Ireland has not spread with such rapidity as one would naturally have predicted, considering how successful it has proved. Although its growth has been slow, it has not been arrested, and now that a sure foundation is formed continued progress is probable, and we may hope, before many years are over, that an industry of national importance will be built up.

While writing of the Irish bulb farms, we may appropriately add a word or two about the Alderborough Anemones which have graced many exhibitions during the last two or three years, and have delighted all who have seen them by their rich and brilliant colouring. They are grown in the nurseries at Geashill, King's County, by Messrs. Reamsbottom and Co., who have done much to popularise these useful flowers and disseminate information concerning them, and at the same time have

demonstrated what very fine Anemones can be produced in Ireland.

There are districts in England, too, quite suitable for the production of good bulbs. In Lincolnshire they are largely grown, and in Surrey; a few years ago they were, and probably still are, grown in the Royal Gardens, Kew. If the possibilities of the British Isles as bulb-producing countries were fully developed we might at least considerably lessen the imports of Dutch-grown bulbs, and so, while keeping money in the country, use it with advantage to both masters and men.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

October 4.—Royal Horticultural Society's Fruit Show in New Hall (three days).

October 4.—Horticultural Club Dinner, 6 p.m., Hotel Windsor, Sir George Watt on "Indian Primulas."

October 5.—National Chrysanthemum Society's Show at Crystal Palace (two days).

October 12.—Royal Botanic Society's Show.

October 12.—United Horticultural Benefit and Provident Society's Annual Dinner, Mr. W. A. Bilney in the chair, 6.30 p.m., Holborn Restaurant.

October 18.—Royal Horticultural Society, Meeting of Committees, 12 noon.

October 25.—Croydon Chrysanthemum Society's Show (two days).

October 27.—Exmouth Chrysanthemum Show.

November 1.—Bournemouth Chrysanthemum Show (two days); Brighton Chrysanthemum Show (two days); Royal Horticultural Society.

November 2.—National Chrysanthemum Society's Show at Crystal Palace (three days); Southampton Royal Horticultural Society's Show (two days); Highgate Chrysanthemum Show (three days); Lowestoft Chrysanthemum Show (two days); Portsmouth Chrysanthemum Show (three days).

November 3.—Weybridge Chrysanthemum Show; Colchester Chrysanthemum Show; Forest Gate Chrysanthemum Show (three days).

November 4.—Windsor and Eton Chrysanthemum Show; Battersea, Clapham, and Wandsworth Chrysanthemum Show (two days); Hinckley Chrysanthemum Show (two days).

November 5.—Batley and District Chrysanthemum Show; Loughborough Chrysanthemum Show; Penarth Chrysanthemum Show; North Lonsdale Chrysanthemum Show.

November 8.—Ipswich and East of England Horticultural Society's Show at Ipswich (two days); Dulwich Chrysanthemum Show (two days); Sevenoaks Chrysanthemum Show (two days); Southend Chrysanthemum Show (two days); Stoke Newington Chrysanthemum Show (two days).

November 16.—Liverpool Horticultural Association Chrysanthemum and Fruit Show (two days).

British Gardeners' Association.—

At a meeting of the committee of this association held on the 23rd ult. it was decided to send delegates of the committee to address public meetings of gardeners in some of the large towns

and centres, and to take immediate steps for the formation of local branches of the association. It was also decided to print at once a certificate of membership and list of rules to be forwarded to all accepted candidates, and that annual subscriptions paid this year will be counted as for next year, before which time the association will not be in proper working order. Up to the present over £160 has been received as subscriptions and donations, and about £70 more has been promised. All who are interested should carefully read the prospectus accepted by the great meeting held in Essex Hall in June last, for it is clear that most of the criticisms and suggestions made through the Press and by correspondence have been made in ignorance of the real character and aims of the association. Copies of the prospectus and forms of application for membership may be had from the secretary, W. Watson, Kew Road, Kew, Surrey.

Narcissus bicolor grandee.—I send a photograph of *Narcissus grandee*, which is one of the most beautiful of the bicolor section. The flowers are delicate in colour, the trumpet, as the illustration suggests, being large and the colour pale lemon, which is in agreeable contrast to the pure white perianth. It is nearly a fortnight later than that well known bicolor *Narcissus* N. Horsfieldi. —D.

Lælio-Cattleya elegans.—On page 233 we give an illustration of the beautiful *Lælio-Cattleya elegans* hybrids in Mr. R. H. Measre's collection at the Woodlands, Streatham. Several notes have appeared in THE GARDEN about these Orchids, and we are glad to be able to illustrate them.

Nerine ingens.—Mr. Gumbleton writes that his collection of over thirty sorts of *Nerines* is coming into flower, and *N. ingens* is the largest flowered of them all. It is very beautiful at the time of writing (September 22), five good spikes out of a potful of ten bulbs, the increase from one bulb purchased in 1899. It was raised by Max Leichtlin, Baden-Baden.

Hybrid Kniphofia Phoenix.—Mr. Gumbleton also mentions that he has in flower a most distinct and beautiful hybrid *Kniphofia*, also raised by Max Leichtlin, named *Phoenix*; it is the result of a cross between *K. comosa* and *K. Leichtlini*, and shows the character of both parents, but resembles the first named in beginning to expand its flowers in the middle of the spike.

The sale of insecticides.—Mr. G. H. Richards has written to the *Dover Telegraph* with reference to the death of a lady there through taking XL All Liquid Insecticide. Mr. Richards says: "I have little doubt that this lady obtained a quantity of the compound named above as the result of reading a report or reports of the Pharmaceutical Society's prosecutions. The society is continually instituting prosecutions against seedsmen and others for selling poisonous compounds. As a consequence the newspapers by their reports of the proceedings are constantly affording the public information as to the deadly character of preparations which otherwise would be known to comparatively few, and used by them for specific purposes." Mr. Richards goes on to deplore the zeal of the Pharmaceutical Society, and thinks that their efforts in this direction do more harm than good.

Memories of Dean Hole.—The Rev. David R. Williamson writes to us from Kirkmaiden Manse, Wigtownshire, Scotland, as follows: "I had the pleasure of knowing the late Dean of Rochester both personally and by correspondence. Some years ago he sent me two fine specimens of the first Rose that had the honour of being associated with his name, viz., Reynolds Hole, raised by Messrs. Paul and Son of Cheshunt, with the following characteristic and memorable description: 'My namesake is affiliated to the Duke of Edinburgh. It is uncertain, coy, and hard to please, yet exquisitely lovely when in good humour.' In another of his letters he says of other flowers: 'I place the Lily next to the Rose, as you do. Ah! that lovely *Tropeolum (speciosum)* which will not thrive in England, but clothes your Scottish cottages with such abundant glory! I plant and plant, and receive feeble encouragement—and then, farewell!'

He thus characteristically acknowledged the dedication of one of my poems: 'I am thankful, and all who read your beautiful poem on "The Ministration of Flowers" will share in my gratitude, that I brought to you the small luciferous match which has kindled such a pure and bright flame. Your verses remind me of Longfellow's on the same subject, and are quite worthy to be associated with them.'

Seacombe cottage gardens.—For many years past Mr. Charles Birchall, who owns the property known as the Cottages, Wheatland Lane, Seacombe, has encouraged his tenants to beautify their gardens by awarding annually prizes for the best kept gardens, window-boxes, and homes in connexion with these cottages. This summer's awards were distributed recently in the Wesleyan Mission Room, Oakdale, in the presence of a large gathering of the tenants and their friends.

Horticulture in Italy.—This seems to be on the increase, and there is no doubt that the great international show recently held in Turin will do much to encourage the growing interest. We have just received a specimen number of a new monthly gardening paper, entitled *La Villa ed il Giardino*, edited by Signor N. Severi of Rome. Although unpretentious in style, the new undertaking gives promise of being a useful periodical to the Italian amateur, of whom there is an ever-widening circle. —A. H. P.

Gladioli among Pæonies.—Where Pæonies are grown in masses in beds or borders, and that is how they should be planted after the flowering season is over, the beds are bare and devoid of brightness. If Gladioli of various forms, such as *Gandavensis*, *Nanceanus*, *Lemoinei*, and *Childsii*, are planted they will produce throughout August and September a capital effect, and make an otherwise dull part of the garden quite bright, and be useful also in providing flowers for cutting. —E. M.

Tritoma glaucescens.—Among Flame flowers, and there are many sorts, none is more effective than *T. glaucescens*. The habit of growth is moderately vigorous, flower-stems are freely produced, while the colour is not only striking in the distance, but upon close examination it is pleasing, the upper part rich red and the lower or expanded flowers deep orange-yellow. —E. M.

Polygonum equisetiforme at Kew. This interesting plant is now flowering freely at the foot of a wall with a warm southern aspect at Kew. It is somewhat rare in gardens, although its light and elegant habit, as well as its period of flowering, should recommend it for cultivation to those who are able to provide the kind of position it requires. It is a native of parts of Southern Europe and of some of the islands in the Mediterranean, where it is usually found in the gravelly beds of torrents. As its specific name implies, it has the appearance of some of the *Equisetums* before it comes into flower, and is almost devoid of leaves. It forms a bushy, very freely branched plant about 2 feet high, and commences to produce its myriads of small white flowers early in September. They are borne in long racemes, imparting to the plant a graceful feathery appearance. With sweet-scented flowers this plant presents a striking contrast to the better-known members of this genus, most of which are remarkable for their robust growth and spreading habit. —W. I.

Aberdeen Botanic Garden.—During the four years which have elapsed since Miss Cruickshank kindly provided the means of laying out the Botanic Garden at Chanonry, Old Aberdeen, steady progress has been made in establishing a representative collection of plants for botanical study. The funds available do not permit of any attempt at making the garden one of great attraction to the general public, but Professor Trail has, with the assistance of Mr. George Nicholson, who acted as adviser in the laying out of the garden, made this small botanic garden one of great service to students of botany. A prominent feature is a capital collection of wild plants, comprising the greater number which are natives of the north of Scotland. This is of great service to many interested in the botany of the district, giving excellent opportunities of verifying

specimens they may collect, and of considerable interest even to the casual visitor. There is no accommodation available for housing sub-tropical or tropical plants, the two greenhouses being mainly used for propagation.

Hedychium gardnerianum in the open.—When this *Hedychium* was first introduced into this country it was thought to require a high temperature, one writer going so far as to recommend its culture in the moist stove. As a matter of fact it is almost hardy, being a native of the temperate regions of the Himalayas. Over seventy years ago Wallich, the great Indian botanist, described it as "the queen of the genus," which it still may be considered. It throws up annual growths, clothed with large Canna-like leaves 18 inches in length and 6 inches in breadth, to a height of 5 feet, crowned by flower-spikes 1 foot in length of pale yellow blossoms, not unlike Orchids, which are deliciously scented. The other day, when in Southern Cornwall, I saw a large bed filled with this *Hedychium*, and was informed that in September fully fifty flower-spikes would be borne simultaneously by the plants. It is no uncommon thing to find it flowering well in the early autumn in the south-west, but as it delights in water during its period of growth it is often a difficult matter to keep it adequately supplied in dry weather when permanently planted in the open. In districts where the winters are too severe for it to be allowed to remain in the open it may be lifted, potted, and kept under glass until the early summer, and then replanted in the open. It also succeeds well in pots plunged beneath the water level. —S. W. F.

Pentstemon Newbury Gem.—It is gratifying to find that this *Pentstemon* is again beginning to attract notice after being in obscurity for a good many years. Really hardy *Pentstemons* of its class are too scarce to neglect this; it can be cultivated for years as an ordinary border plant without the trouble of annual propagation. Not that it has the same features as the great *Gloxinia*-like flowers of the modern hybrid *Pentstemons*, for the blooms are narrow tubed and do not open at the mouth like those of the hybrids. Its hardness and its fine scarlet colour are, however, great merits. It was well shown in a group of hardy flowers exhibited at the Royal Caledonian Society's show in Edinburgh on the 14th and 15th ult. by Mr. John Forbes of Hawick, but it is a plant I have known for many years. In appearance the flowers remind one much of those of *Phygelius capensis*. The origin of *Pentstemon Newbury Gem* seems difficult to trace, and I have looked in vain through a number of books without finding any record of its origin. The name, however, of Newbury Gem may be a means of its being traced, and I for one would be glad if anyone could throw any light upon the source of this pretty *Pentstemon*. —S. ARNOTT.

The Pomegranate (Punica Granatum).—I always greatly admire the stately standard plants of the Pomegranate growing in tubs which one sees on the terrace of Gunnersbury House during the summer. They grow freely, producing many handsome crimson blossoms. It is said the Pomegranate was first cultivated in England during the reign of Henry VIII., and it is mentioned among the trees that fruited in the Orange house of Charles I., so it is an old inhabitant of English gardens. It is said to thrive out of doors in the warm counties of England and Ireland, but the climate is not sufficiently favourable to bring its fruit to maturity; and even when cultivated under glass in these counties, though the fruit may mature, it does not attain to that delicacy of flavour equal to the produce of Spain, Italy, and other warm climates. It is as a terrace plant grown in tubs or boxes that I wish to commend it, and it is by no means difficult of management, needing protection in a greenhouse during winter, and being suitably top-dressed during early summer and kept well watered. The Myrtle, *Aloysia citrodora* (sweet-scented Verbena), the Orange, &c., make excellent companions to it, and set off a broad terrace to the best advantage. Some bush-trained Fuchsias and scented-leaved Pelargoniums go well with them. —R. D.

Fuchsia Charming.—For growing in tubs, vases, or large pots, as specimens on the lawn and so on, no variety that I know can excel Charming, the plum-coloured corolla contrasts so well with the red sepals and green foliage. Habit of growth and freedom of flowering are so remarkable that it is difficult to imagine a finer Fuchsia than Charming.—E. M.

Phygelius capensis.—This is a valuable plant for the autumn, for from the end of August until the first frost it continues to bear its spikes of long bright crimson flowers with yellow interiors; indeed, I have picked a perfect spike as late as December. It is practically perfectly hardy, as it has in this country endured a temperature some degrees below zero without being harmed. In severe cold such as this the growth above ground is killed, but it throws up shoots strongly from the roots in the spring. In warmer districts it maintains a shrub-like habit, its growths remaining intact through the winter. It is certainly disappointing in some gardens, and where it refuses to bloom freely it is not worth keeping. Where, however, it proves floriferous it is a handsome addition to our autumn-flowering plants. The other day I saw in the neighbourhood of Chepstow a remarkably fine bush in full flower. It was 4 feet 6 inches in height and 6 feet through, and was bearing forty-seven bloom-spikes, some of these being 9 inches to 1 foot in length. It was introduced from the Cape in 1855.—S. W. F.

Amaryllis Belladonna purpurea major.—Those who admire the Belladonna Lilies, and have so far failed with the type plant, should try the variety *purpurea major*. It is a distinct and very beautiful form, and certainly of more easy culture than the type. The bulbs are as large as the largest Coconut, the leaves unusually broad and lustrous, the flowers numerous and borne on stout purplish stems 2 feet or more high, and they resemble the type in shape, but are larger and more richly coloured, the throat lined with rich pink, and not so clearly white as in the old Belladonna. This variety, by the way, cannot be called new, for a large continental grower has grown it for twenty years in the open, and in a far worse climate than this, and a fine display within eight miles of Charing Cross is ample testimony that the plant is a good doer, and that it will flower freely where the ordinary Belladonna fails. One can grow it well in an ordinary border also, provided the situation is warm. Its fragrance is very marked, and one must welcome such a grand variety of an old favourite at its true worth. It is a very distinct plant that I can heartily recommend from personal experience of its merits.—G. B. M.

Rudbeckia maxima.—This plant does not succeed in every garden, and growers in the Midlands and other winter-wet districts will experience difficulty in managing it. It is seen at its best at high elevations and in a light gravelly soil. The leaves are very glaucous, and a welcome bit of broad, semi-tropical leafage in the plant border in early summer. The stems grow 6 feet in height, and bear striking flowers of a rich yellow with orange shading, the large black cones showing in splendid contrast. The whole plant has a glaucous hue, and it is very striking when in good health. There are several spurious forms in cultivation, and one or two bad varieties, but the true plant is very handsome. It flowers during August and September, and it is not likely to be seen at its best till well established. A mulch of dry material is necessary in very severe winters, for the plant is just on the borderland of hardness in this climate. In the south this plant should be appreciated, for, in truth, it is a striking object when in flower. Texas claims it as a native.—G. B. M.

Early-flowering Chrysanthemum Carrie.—Although the flowers of this variety cannot compare with those of Horace Martin—the yellow sport of the Mme. Marie Masse family—they have a charm of their own. There is room for both of these yellow sorts, their respective shades of colour being quite distinct. The plants have been in flower for several weeks already, and there is the probability of the display being continued for many weeks to come. The smallest pieces put out in the open border in May last have made

pretty dwarf and bushy specimens, and new shoots continue to spring from the base, each one bearing quite a heavy crop of buds. The flowers are seen to advantage when the plant is partially disbudded, their form being better and the individual flowers more attractive. This year the plants are rather less than 2 feet in height.—D. B. CRANE.

New Chrysanthemum R. Pemberton.—Early Chrysanthemums of a clear amaranth colour are quite limited. Not that many of this shade are needed, but we want the best of whatever the colour may be. Last season, at Ryecroft Nursery, this seedling was much admired, and now that the plant is distributed far and wide it is gratifying to hear that it is doing well in places and situations widely diverse. At Tamworth, in June last, an early batch of this variety was quite one of the best things in the whole collection. I have since seen the plant on heavy land at Mr. Jones's new nursery at Keston, Kent, where it is doing remarkably well. In my own collection it is also one of the most promising of the 1904 novelties. The plants should be grown without disbudding, in which case the crop of blossoms is most prolific. The flowers are borne on stout, erect stems, on plants possessing a splendid habit. Height about 3 feet.—D. B. CRANE.

At the Warley cottage show.—The accompanying illustration shows the group of

described in the early part of the "Dictionary of Gardening" as a cross between *Z. tubispatha* and *Z. carinata*, under the name of *Z. tubispatha hybrida*, of which *Z. spofforthiana* is quoted as a synonym. As this was figured in the *Botanical Register* (1815 to 1847), it must have been obtained many years ago, and is now, I fear, lost to cultivation, at all events I cannot find it mentioned anywhere else, not even in the "Kew Hand List."—T.

Senecio tanguticus.—During a recent visit to Kew I was more than ever impressed with this new Chinese species of *Senecio*, which is certainly one of the most desirable members of this extensive genus. As a foliage plant alone it is most handsome, the erect stems, which reach a height of 3 feet to 5 feet, being clothed with palmately-lobed leaves, the divisions of which are deeply cut. The small yellow starry flowers are borne in large erect pyramidal-shaped panicles, and though individually they are by no means showy, yet in a mass a delightful effect is produced. This *Senecio* is a native of Central China, and is one of the many good things introduced from there by Messrs. Veitch, through their collector, Mr. E. H. Wilson, who sent home seeds from which plants were raised that flowered for the first time at Coombe Wood in the autumn of 1902. It is perfectly hardy. A second species of *Senecio*, but widely dissimilar from the last, has

MISS WILLMOTT'S EXHIBIT OF FRUIT AT THE WARLEY COTTAGE SHOW.

splendidly grown fruit from Miss Willmott's garden. The Grapes and Peaches were particularly worthy of note, and the arrangement was very tasteful.

White Thyme.—If you have a very poor bit of ground which parches so much in the summer sun that most things find existence there impossible try the white Thyme. Fierce heat and intense drought appear to have no effect on its welfare, and in its season it is one mass of pure white flowers. A good-sized specimen is very conspicuous when in bloom. A word of warning is, however, necessary. Never by any chance plant it close to choice alpine, for in my experience it is capable of choking any dwarf habited plants.—J. CORNHILL.

Hybrid forms of Zephyranthes.—Having tried many times unsuccessfully to cross the delightful *Z. carinata* with different species, I was much interested in the note on *Z. Ajax* (page 186). This hybrid (*Ajax*) is, I see, mentioned in the last supplement of the "Dictionary of Gardening" as having been illustrated in "Regel's Gartenflora" in 1899. My principal object in this note is, however, to call attention to a hybrid

also flowered beautifully this year. This is *Senecio clivorum*, a native of China and Japan, which, though long known to botanists, was not introduced till 1901, when it was sent home to Messrs. Veitch by their collector. It is a strong growing herbaceous perennial, with bold foliage and rich orange-yellow flowers. It is scarcely suitable for the herbaceous border, but for planting on the margin of a lake or stream there are few, if any, plants more beautiful than this. The leaves are roundish, 1 foot or more across, borne on long petioles, while the much-forked flower-stems bear a wealth of blossoms that remind one of some of the perennial Sunflowers. The individual flower-heads are about 3 inches across, the outer portion consisting of bright orange-yellow, strap-shaped florets, while the central disc is brown.—H. P.

Verbena Afterglow.—This pretty *Verbena* received an award of merit from the floral committee of the Royal Caledonian Horticultural Society at their meeting on the first day of the autumn show of the society. A sport from *Verbena* Miss Willmott, it possesses all the good qualities of the parent, but the colour is a bright and effective rose. It is thus brighter for beds

where a little more colour is desired than is given by the beautiful *Verhena* from which it sported. It was raised in the gardens of the Earl of Haddington at Tynninghame, and was submitted by Mr. R. P. Brotherton for the opinion of the committee, with the result already mentioned. Mr. Brotherton not only showed cut flowers, but plants, so that the committee had ample opportunities of discerning its character.—S. A.

Hardy Fuchsia Caledonia.—This dwarf hardy *Fuchsia*, which was unanimously awarded a first-class certificate by the Royal Caledonian Horticultural Society's floral committee on the 14th ult., appears to be one of the neatest and most free-flowering of its class. The plants shown came from the nursery of Messrs. Cunningham, Fraser, and Co., Comely Bank Nurseries, Edinburgh, the firm having also a small group in their stand of flowers on exhibition at the show the same day. There was thus an excellent opportunity of seeing the character of the plant, and from what one saw of it there can be no doubt that the committee was justified in the award. The *Fuchsia* was shown in compact little plants about 1 foot or a little more in height. The little pyramids were laden with small bright flowers. It appears that this *Fuchsia* was raised at Comely Bank about thirty years ago, but it has not been propagated until lately. It is understood to be a seedling from *Riccartoni*, but the whole appearance reminds one more of *F. pumila* than of *Riccartoni*. It is, however, of a better habit than *pumila*, while the corolla is not so dark as in that species. The flowers are also more freely produced. *Caledonia* grows a little taller than *F. pumila*. When submitted to the committee it was named *Profusion*, but it was pointed out by one of the members that there was already a *Fuchsia* of that name, and it was consequently altered to *Caledonia*, an appropriate name for a plant of its origin, and one that was first shown before the Royal Caledonian Society.—S. ARNOTT.

***Liatris graminifolia* var. *dubia*.**—There are three *Liatris* generally grown, the commonest of which is *L. spicata*, a short tufted plant that flowers in summer. *L. graminifolia* *dubia* is a tall variety growing 4 feet to 5 feet high, bearing a fine series of spikes, which commence to flower from the top downwards. The flowering portion of each spike is generally more than a foot in length, and is exceedingly showy, being made up of a multitude of rich, bright purple Thistle-like flowers, tightly packed on the stems. It is a vigorous border plant, valuable at this season of the year when so few good plants are at their best. The leaves are very narrow and numerous, and the growths, when a foot or two high, may be likened to a clump of seedling Pine trees, and they have the same delicate green colour. It does not appear to be able to seed under cultivation in this country, and propagation is only possible by dividing the curious, knob-like root-stocks, and by severing the smaller growths which form at the base of each stem. The *Liatris* is a native of sandy tracts of country, but under cultivation it succeeds, treated as liberally as is possible, especially the variety under notice.—G. B. M.

***Nertera depressa*.**—This little plant is now a pretty picture on a shady ledge in the rock garden, its whole surface being thickly studded with bright orange berries. It is almost invariably met with under glass, and I have only seen it in the open in one garden besides my own, that of a Somersetshire vicarage. Here, although said to be a native of New Zealand, it appears perfectly hardy, as it has passed through three winters unprotected without the slightest injury and has increased to quite double its size when first planted out. It is growing on a ledge in front of an upright rock, and shares its quarters, which have a northern exposure, with *Philecia buxifolia*, *Shortia galacifolia*, and *Ourisia coccinea*, the last of which is spreading so rapidly that it will soon have to be reduced. The soil in which it is planted is pure peat and granite sand. The flowers are inconspicuous, being very small, pale green in colour, and borne in the axils of the leaves. These are followed by minute green berries, which gradually swell and begin to show colour early in August, remaining in full beauty for

three months. All who possess a rock garden and are blessed with a mild climate should grow this pretty little plant, which is interesting even when not bearing berries, as its close mat of tiny pale green leaves clinging closely to the ground renders it distinct from all other rock plants.—S. W. FITZHERBERT.

***Buddleia variabilis veitchiana*.**—This is a distinct improvement upon the ordinary *B. variabilis*, the flowers being much richer in colour, which may be described as heliotrope-purple. The shrub appears to make amazing progress, and is probably the quickest grower of any garden shrub or tree. Small bushes of *B. variabilis* put out in the spring of 1903 are now immense bushes, 10 feet in height and as much through. In the spring I was given a tiny plant of the variety *veitchiana*, about 6 inches in height. This was planted out in the garden, and now has shoots 7 feet in length, while it has been flowering freely for the last fortnight. The bloom-racemes are now over 1 foot in length, but I have seen some on larger bushes that exceeded 2 feet in length.—S. W. F.

***Calystegia pubescens flore-pleno*.** This pretty double Bindweed is not such a dangerous plant to introduce into a garden as the majority of its family, since, although it often shifts its position a foot or two, it is not a bad land-grabber; indeed, in cold and damp soils it often proves difficult to establish in the open. Its double, flesh-pink flowers have been very pretty for the last month, the shoots running up a wire trellis in company with a Honeysuckle, they will continue to bloom until the first frost. It makes shoots 6 feet or 7 feet long in a season, and is at home climbing over rough rock-work, old tree roots, or low bushes, so that it is available for a diversity of positions. It was introduced into this country from China in 1844.—S. W. F.

***Asparagus subulatus* var. *gracilis*.**—This pretty *Asparagus* is quite new to cultivation. It is a native of the Himalayas, and was introduced by Mr. Sprenger. It is a tall climbing evergreen species, with very small spines, leaves dark green, not prickly. The flowers are borne in racemes, each with twelve to eighteen sweet-scented white flowers with orange-coloured stamens. It is grown all the year round in the open here. For cutting purposes and as a pot plant it is most valuable.—W. MÜLLER, *Vomero, Naples*.

***Clematis Hilarii*.**—This new introduction of Mr. Charles Sprenger is now flowering for the first time in the well-known garden of Gennaro Casertano, Esq., of San Giorgio Cremano, near Naples, one of the best gardens in the neighbourhood of Naples. It was planted in the spring as a small plant on a pergola, between climbing *Roses*, *Solanum seafortianum*, *S. jasminoides*, *Mandevilla suaveolens*, *Polygonum baldschuanicum*, and others, and has now reached a height of about 2½ metres, well branched from the base. From the top of the long branches and also from the axils appear the long panicles covered with myriads of bluish white sweet-scented flowers. The leaves are large and dark green. It is one of the finest climbers. I believe that this species would be quite hardy in Britain. It comes from Argentina, so rich in fine flowering plants.—WILLIAM MÜLLER, *Vomero, Naples*.

Excessive railway charges for fruit.—The extent to which the fruit trade is handicapped by railway charges may be judged from the following: A local grower sent a consignment of Plums to Glasgow, the net weight of the fruit being 23cwt. 2qr. The consignment realised £13 18s. 8d., out of which no less than £6 12s. had to be paid for freight. There was also a charge of 2s. 8d. for receiving and delivering. Is there another industry which could possibly live under such conditions? Deducting the salesman's commission, the actual amount received by the grower for his 23cwt. 2qr. of fruit was £6 9s. 6d.

***Hemerocallis* Dr. Regel.**—Mr. W. E. Gumbleton writes from Belgrove, Queenstown: "I have now in flower a very distinct hybrid *Hemerocallis* named Dr. Regel, unlike any of those known to me in its deep orange shade of colour,

and in having all its three or four flowers in a compact bunch on the top of the flower-spike, and enveloped in a sheath exactly like that of an *Agapanthus*, instead of an open panicle like all the other sorts have; the flowers open quite flat in the sun. It is a very beautiful hybrid."

***Aconitum Wilsoni*.**—This member of the Monk's Hood family is remarkable for its exceedingly glossy leaves, and from the fact that it blooms during September and October when nearly all its relatives are over. After the terminal spike is past its best the secondary ones develop rapidly, and continue the floral display for some time. The introduction, or perhaps I should say reintroduction, of this species we owe to Messrs. Veitch, whose collector, Mr. E. H. Wilson, sent it home from China. It appears, however, to have been figured in the *Botanical Magazine* some years previously as *A. Fischeri*, but there is another plant bearing the same name which in the "Kew Hand List" is referred to as *A. columbianum*. At all events, whatever name may be regarded by botanists as the correct one for the plant known as *A. Wilsoni*, there can be no question that it is a most valuable addition to autumn flowering perennials, and a decided break away from the different tints of yellow which greatly predominate at this season. In colour the flowers of *A. Wilsoni* are of a pleasing shade of violet, while the hood-like portion of the flower is much developed.—H. P.

THE ROSE GARDEN.

WHITE BEDDING ROSES.

HOWEVER much we may value crimson and scarlet *Roses* for massing, and wish there were more of them, snowy white and creamy white varieties are none the less appreciated. It is astonishing how many *Roses*, when seen from a short distance, are white in effect, although on close inspection there are subtle charms and tints that are only apparent upon a closer view. Several varieties may be called snow-white, such, for instance, as *Baronne de Maynard*, *The Queen*, *Fran Karl Druschki*, *Katherine Zeimet*, and *Anna M. de Montravel*, these two last being dwarf *Polyantha* *Roses*. They are all very beautiful, and may be freely planted where pure white flowers are wanted. Then comes the section of flesh-white *Roses*, headed by the Hon. Edith Gifford, a splendid sort that gains in popularity every year. *White Lady* is magnificent, especially in June, when its huge blossoms are the wonder of all who see them, produced, as they are, upon very dwarf plants. *Augustine Guinoisseau* and *Souvenir du President Carnot* are excellent, the former a white *La France* and very sweet, and the latter a most refined and deep flower, which is not conspicuous upon the plant quite so much as one could desire. *Marjorie* is a little gem, one of the prettiest of this very charming group of hybrids.

Creamy white *Roses* are really white in effect, more so, of course, in the distance. Peace may be fittingly placed at the head of this group. It is a grand *Rose*, destined to become one of our best bedding kinds. *Enchantress* is also very good, yielding fine clusters of most beautiful blossom. *Mme. Pernet Ducher*, *Sulphurea*, *Kaiserin Augusta Victoria*, *Yvonne Gravier*, *Mme. Berkeley*, and *Mme. C. P. Strassheim* are each one distinct, yet for all practical purposes alike in the mass. There are many other white *Roses*, but the above selection seems to me the best. I must not, however, overlook the beautiful varieties known as *White Caroline Testout*. There are three, each one distinct, yet all coming under the category white—*Admiral Dewey*, *Marguerite Guillot*, and *Irene*. Probably it will be granted that *Marguerite Guillot* is the best, but I should advise all who want three good white *Roses* to plant the lot, for they are worthy of it. P.

ROSE DUCHESS OF MECKLENBURGH.

FOR a pillar or pergola this *Rose* well deserves a place. The growth is vigorous, the foliage a deep

green, and its flowers are freely produced, especially during the month of September, when the bulk of rambling Roses are flowerless. The blossoms are semi-double, white, flushed with yellow in the centre. E. M.

ROSE MARQUIS DE SALISBURY.

AMONG autumn-flowering Roses it is difficult to imagine a more suitable variety than this where dwarf growth and a mass of flowers are required. The bright crimson blossoms render it a conspicuous object, even at a distance. E. M.

ROSE LADY BATTERSEA.

PERHAPS the finest plants of this Rose outdoors are to be seen in Lord Battersea's garden at Overstrand, where a bed of fifty of the first raised plants were placed some three years since. I have seen them annually ever since, and must say the growth this year is even better than I have seen it before, while the flowers are very fine. It is a Rose that should be grown everywhere. E. M.

ROSE G. NABONNAND.

FOR September flowering in a mass this is one of the best of Roses. I lately saw it growing in a bed 15 feet in diameter. The plants had made stout, vigorous growth, and were giving a huge crop of soft creamy pink blossoms. Even when fully developed this is a desirable Rose, as it preserves a good form; but it is in the bud state that it is so much appreciated. E. M.

ROSE PRIMULA (DWARF POLYANTHA).

A DAINTIER little Rose I am not acquainted with than the variety Primula, which was raised and distributed by Messrs. Souper and Notting three years ago. The flower is almost single, there being no more than three rows of petals, revealing the golden stamens and wonderful white centre, and contrasting so prettily with the bright China Rose of the upper part of the petals. It is the white eye that is so attractive, and this is still more prominent owing to the brilliant colour of the remainder of the flower. Doubtless the combination of colour and form of flower suggested the name. Being a dwarf grower and free bloomer, Primula will become popular. It is such thoroughly distinct novelties as this that are wanted at the present day. Apparently the possibilities of novelty in the Rose are inexhaustible. What with the many agencies at work in the hybridisation of this beautiful flower, and its own inclination to sport, some remarkable developments may be looked for in the near future. P.

ROSA POLYANTHA NANA.

It would be interesting to ascertain the exact history of the dwarf Polyantha Roses which were put into commerce about ten years ago to be treated as annuals. It is no fable that seedlings will grow into flowering size within the space of three to four months, as it has been done over and over again in this garden. Last year seed was sown under glass on February 10, which showed the first seed leaves on March 13, and flowers opened on June 25, three months and twelve days from the date of germination. One of these planted on a wall continued to flower charmingly throughout the season until November. At the beginning of April this year it was moderately pruned back and was the prettiest little bush imaginable, about 12 inches in height, completely covered with clusters of pale pink single flowers and deeper tinted buds during June and July. The dry hot season after that made it look somewhat rusty and shabby, and it was again well trimmed. The brave little bush is now flowering once more, and is well set with fresh clusters of buds. Few plants could give a better flowering record. As a general rule Rose seeds are slow in germinating. If these little Polyantha Roses were merely of annual duration the quick springing of the seed might be easily accounted for; but, on the contrary, they are true perennials and improve

year by year. They are not all single flowered, as many of the seedlings give double and semi-double forms; but the single are as pretty as any, and all make admirable wall or rock garden bushes. One would be glad to know more of the origin of these useful miniature Roses. Indeed, not one passer-by in a dozen ever recognises them as being Roses at all, the general effect being more like that of Apple blossom. K. L. D.

SOME SUMMER AND AUTUMN - FLOWERING BULBS.

(Continued from page 204.)

BRODLEA.—This is a large genus, and some of the species are very rare or not yet in cultivation. Many of them are easily procurable, and not being difficult to grow in soil and situations recommended for Bloomeria

and Brevortia, should be tried by all lovers of good things. Perhaps the best and most satisfactory are the magnificent *B. californica*, with flowers from rose to deep purple; congesta, blue or violet; Douglasii, bright blue; gracilis, deep yellow, rather tender; grandiflora, violet-purple; Howelli, bluish white, and its finer variety lilacina, lavender; ixioides and var. erecta, bright yellow; laxa and l. splendens, pale to dark blue (Mr. T. Smith's laxa maxima is a decided acquisition, being of a fine deep colour, and considerably later than the typical form); peduncularis, bluish white to rosy; and the newer Orcuttii, Purdyi, and sellowiana, though with regard to the last-named I am inclined to think it blooms in spring, not summer.

B. volubilis (or more properly speaking, *Stropholirion californicum*), with long twining scapes and large umbels of rose-coloured flowers, is rather tender, but is well worth trying in a select corner. It flowers in July.

CALOCHORTIS.—This beautiful genus, including the Star Tulips and Mariposa Lilies, is now so well known and appreciated, and so much has been written about its cultivation out of doors, that I do not propose to do more than briefly allude to my own experience with the venustus section. I have already written on this head in the pages of THE GARDEN at some length, and a photograph of my group in full flower appeared in the number for August 15, 1903. I have grown them now in the same bed for seven years or more on a warm, thoroughly well-drained border with a decided slope to the south, composed of very light deep soil; they have never been lifted or interfered with in any way, and have seldom

been covered with the frame-light so universally recommended directly after the flowering is over. They have increased by their own seeds, which are left to look after themselves, a slight covering of fine peat and ashes being added each November. New beds should be thoroughly dug and pulverised and the bulbs planted in September. A sloping layer of cinders or brick rubbish below the soil would be an undoubted advantage, even in soil naturally light, for drainage is the key, in my humble opinion, to success, with these charming flowers, as it is indeed with Ixias, Sparaxis, and a host of other bulbous plants. All the species of this fascinating genus are most desirable, and it is difficult to single out any one as more worthy of a trial than another. My advice to intending growers is to get a grower's catalogue and study the extensive list it contains. The venustus section is, perhaps, the easiest to grow, and it contains many exquisite varieties, but special mention may

also be made of pulchellus, clavatus, and Purdyi.

CAMASSIA.—The fine species *C. Cusickii* hardly comes within my province, as it flowers in the spring, but the other members of the genus, *esculenta* and its varieties, *Fraseri* and *Leichtlini*, are all handsome and worth growing. I do not know anything about *C. Engelmanni*, a bright blue species from the Rocky Mountains, but it is well spoken of. Deep, well-drained soil, with a warm aspect, not too much exposed to the sun, suits these fine plants, which are splendid in masses.

COLCHICUM.—The Meadow Saffrons are beautiful and easily grown, blooming in autumn, when

NARCISSUS GRANDEE. (Much reduced. See page 218.)

flowers are scarce, but as the scapes come before the leaves and are somewhat weak and "floppy," suffering much in high winds or heavy rains, it is desirable to have them in grassy corners of the lawn or wild garden, or to carpet the border where they are growing with some dwarf plant such as a small Veronica or Sedum. This forms an agreeable setting for the flowers and helps to support and preserve them. Moist sandy loam is the best soil for Colchicums. There is not a great range of colour in the flowers, which vary from pure white to rosy purple, but all the forms are pretty and welcome. *Sibthorpii*, with its fine chequered flowers, is perhaps the most desirable, though the commoner *Parkinsoni* runs it very close. *Bornmulleri* and *giganteum* are magnificent new species; *speciosum* is an older one, but remarkably fine; the double white form of the well known autumnale is a scarce beauty which should be in every collection. I have a very good large form from Mr. T. Smith, of Newry, called *persicum*.

EUCOMIS.—Every one who has a spare piece of warm sunny border, preferably under a wall or on the sheltered side of rockwork, would do well to try one or more species of the small genus *Eucomis*, the best of which are probably bicolor and punctata. Their graceful foliage and stout flower-spikes are very effective, and the conspicuous blossoms of punctata, appearing from July to September, are sweetly scented.

FRITILLARIA.—The *Fritillaries* form a most interesting genus to which sufficient attention has not been given by amateur gardeners, but they have not yet perhaps been satisfactorily worked out by the botanists, and it is a most difficult matter to approach them scientifically with our present knowledge. Most of them flower in the spring, but a good few are in bloom in the summer months, such as *camtschaticensis*, *Moggridgei*, *pyrenaica*, &c. Curious and interesting rather than pretty, *Fritillaries* are specially suitable for planting in grass in half-shady spots, or in nooks in the border more or less screened from the direct rays of the sun. As a rule they prefer a light rich soil, thoroughly well drained; the fastidious and handsome *recurva* has done fairly well with me in nearly pure sand, in full sunshine, having flowered for the last three years consecutively.

GALTONIA.—A small genus of handsome South African bulbs, well known to all through the popularity of *G. candicans* (*Hyacinthus candicans*, or Cape Hyacinth). The other species, *princeps*, *clavatus*, and a hybrid between the two, *princeps-clavatus*, are less ornamental and probably not worth growing. *Galtonias* like an open sunny spot and light rich soil, well drained, in which they will flourish and give a splendid effect for years, with the assistance of a good autumn mulch of old manure. The bulbs should be planted fairly close together and about 6 inches deep.

HYACINTHUS.—As the lovely *H. amethystinus* flowers in May and June I think I am entitled to include it in my list without laying myself open to the charge of poaching in the spring preserves. It is an indispensable flower; a mass of the ordinary form, with a few of the white variety here and there, in clumps or singly, dotted about it, will delight both eye and soul, especially as it is in full beauty long after the glory of the *Scillas* and *Chionodoxas* is past. The bulbs are not expensive nowadays, and the white form is only slightly dearer than the blue.

LILIUM.—What am I to say about the Lilies? As I have already trespassed grievously on the space available in this number of *THE GARDEN*, I think I had better say nothing at all. One cannot touch lightly on this most beautiful genus, it would be an insult to such a divinity; and, moreover, I am living in the hope that I may be allowed in a future number to say something about the behaviour of Lilies, especially with regard to the season of 1904. So I will pass on to the far less showy but interesting

LLOYDIA, a rare and pretty genus, comprising but two species, one of which, *L. serotina*, was originally discovered on the rocky ledges of Snowdon, in North Wales, though it has probably been long since exterminated by greedy collectors in that locality. It is found in the Alps, also in Central and Northern Asia and in North America. The other species is Himalayan, and I have never seen it under cultivation. *L. serotina* bears its neat flowers on short, slender stems in June; these are white or yellow, veined with green. In partial shade and sandy loam it may be used with advantage, and it is a pity it is so seldom met with.

MERENDERA.—The best known autumn-flowering species are *M. Bulbocodium* (also

called *Bulbocodium autumnale*) and *M. persica* or *Aitchisoni*, both with very pretty, rosy lilac flowers, which come before the leaves. Near allies of the *Colechicums*, they require the same treatment, and look all the better if planted in a carpet of some low-growing perennial, which retains its foliage throughout the winter. *Bulbocodium vernum*, though it occasionally flowers as early as January, hardly comes within the limits of this list.

MILLA.—For the solitary species left by the botanists in this genus, the lovely *M. biflora*, a warm sunny corner, thoroughly well-drained, and a good light sandy loam are essential. The flowers appear in August and continue for weeks, even months; they are so pretty that all should make an effort to find a suitable spot for a clump of these desirable bulbs.

NOTHOSCORDERUM.—This genus contains a good number of species, but only one, *N. fragrans* (*Allium fragrans*) is of any importance. This fine plant, with umbels of fragrant white flowers, barred externally with lilac, is quite hardy, and flourishes in good light soil in sunny borders or in back portions of the rockery; it blooms in the summer months.

ORNITHOGALUM.—Like the *Alliums*, these flowers are, unfortunately, endowed with an Onion perfume, the reverse of divine, and many growers object to their presence in the garden on that account. The magnificent *O. arabicum* is one of the worst offenders, but it is so handsome and effective that it can hardly be dispensed with, and, after all, the "bouquet" is local and not overpowering. It is a great pity it is not quite hardy, but in rich well-drained soil, well protected by ashes or dry leaves in winter, it does not do badly in the south of England, and should certainly be attempted. Other good summer species are *pyramidale* and *pyrenaicum*, which will grow in partial shade, or in the wild garden among shrubs, *narbonense*, and *latifolium*, but *arabicum* is the best of all, with its large creamy white flowers, which have yellow anthers and a conspicuous black ovary in the centre.

SCILLA.—Among the numerous hardy and exquisite *Scillas* we have only one that flowers in autumn, before its leaves appear, viz., *S. autumnalis*. It is quite worth growing, independently of its abnormal time of blooming, for the reddish purple flowers are very delicate and attractive, while the variety, or form, *japonica*, with lovely rose-coloured flowers, is a decided acquisition.

TULIPA.—We have not yet arrived at an autumn-flowering Tulip, all the numerous species in cultivation, with one exception, blooming in the spring. This exception is the handsome *T. Sprengeri*, an Armenian species, which does not come to perfection till the end of June in ordinary seasons, and thus becomes a most desirable addition to our bulb list. It is rather a tall grower, with brilliant scarlet flowers, and has done well with me on a warm border, producing fertile seed freely.

Yalding, Kent.

S. G. R.

SOME GOOD NEW DAHLIAS.

MR. J. C. RANDALL (Single).—This new single variety received a certificate of merit at the Alexandra Palace show on the 7th inst. The flowers are of good form. It is quite distinct from any existing variety in regard to colour, this being a lovely deep shade of rose, flaked and striped deep crimson, with a bright yellow disc. The plant is free flowering, and should prove an acquisition to this section. This new sort was exhibited by Messrs. J. Cheal and Sons, Crawley, which firm has done so much to

make the single-flowered sorts popular. If the flowers are gathered long before they are fully expanded they continue to develop subsequently, and last much longer as a consequence.

Effective (Cactus).—Among the large number of new sorts, in which there is a tendency to encourage those developing huge flowers, it is pleasing to meet with one like the above. This variety has blooms of the most refined and dainty kind. They are just large enough for many forms of decoration, and surely for exhibition too. They are of good form, the florets being regularly and evenly disposed. The colour is a soft amber, slightly tinted rose, and with a rose centre. The flower is aptly named, as it is most effective. The plant has a splendid habit, and develops its flowers freely on erect footstalks, and for this reason has a special value in the garden. An excellent display of this sort was recently made by Messrs. J. Cheal and Sons of Crawley at one of the great London shows.

Stromboli (Single).—This is another fine seedling of this year that received a certificate of merit at the Alexandra Palace show on the 7th inst. The colour may be described as rich velvety maroon, tinged with crimson, and each petal is tipped with white, thus making a distinctly pretty fancy type of the single flower. As a plant for garden embellishment or for use when cut this new sort from Messrs. J. Cheal and Sons should be heartily welcomed.

Ideal (Pompon).—There is a tendency in many instances to get the Pompon sorts too large. The variety under notice was charmingly staged by Mr. J. T. West at the Alexandra Palace show held recently. The flowers are, as the name implies, ideal in shape. A few, however, were just a trifle too large. The colour is a bright yellow. For exhibition or garden use this 1905 novelty should have a good future.

D. B. C.

NOTES FROM SWANSWICK.

THIS summer I had the pleasure of seeing *Edraianthus dalmaticus*, grown from seed, blooming on a rockery here. From the packet of seed there were only three plants, one of which was from a stray seed that had found its way into a box of *Gentiana acaulis*, whose own belonging never came up, though quite a variety of odds and ends, singularly attracted, appeared in it, including *E. rosea* and the one *Edraianthus* aforesaid. I kept the third plant in a pot, and it has not flowered, nor does it look nearly so well as the one planted out in a crevice between two limestone, in very sandy and gritty (made) soil. If this were not rather a difficult subject to raise and flower, I do not suppose anyone would trouble about it; the long semi-prostrate stalk with the close whorl of harebell-shaped darkish purple flowers at top has nothing specially fascinating in its appearance, and it lasts but a very few days in beauty. A large patch, however, would be a different thing. My favourite among the less common dwarf *Campanulas* is *C. barbata*. This is so unlike all the others; the pale blue bells are solid in texture, interestingly hairy within, and of a peculiarly pretty shade of colour, while the neat round tufts of prostrate leaves are quite distinct. It is a tidy, compact plant, and does excellently well here in a level nook at the foot of the shady rockery, in rather heavy loam.

Close by it is a thriving tuft of *Soldanella alpina*, which was suddenly discovered to be afflicted with a non-paying guest in the person of a tuft of Grass of *Parnassus*, firmly wedged in its very middle. For some time it had escaped noticed, the leaves of the two plants not being very dissimilar at a little distance. At this time of year anything, poked in anywhere, usually grows, and a division, necessarily

somewhat drastic, of the allies, resulted in successful transplantation.

Dorothy Perkins, acclaimed by ourselves and every visitor to the garden as the prettiest of all climbing, pillar, or arch roses, has not flowered well this year, and the Crimson Ramblers, which are in a place a little shaded, have not flowered at all, while one in sunshine only had two or three bunches of bloom. I fancy this has been the case elsewhere, too, as I have not seen anything like the usual display about in other gardens. Aglaia, however, planted in the same situation and aspect, bloomed very profusely. Billiard et Barre, against a wall in a rather dry border, flowered, and is flowering, well, and made growth, but the blossoms are whitish with a pink tinge, and quite out of character, though of full size and good shape.

The best things now, of course, are the Michaelmas Daisies. The three Perrys—Perry's Pink, Perry's Favourite (Amellus), and Elsie Perry—are all good. Elsie and the Favourite precede Pink, but they overlap. I have raised a pink seedling several shades lighter than Perry's Pink, but very distinctly pure pink, which I think very pretty. It was the only pink one out of a large packet of seed that germinated most freely and gave astonishing variety, and a number of dwarfs from 1 foot to 18 inches, that make delightful rockery bushes.

Symphyantra Hofmanni, like a rather more bushy Canterbury Bell, the ivory flowers of which have had their frilled mouths cut off with scissors, flowered profusely on the shady rockery. *S. pendula*, the perennial, has not flowered yet, though this is its second season, and it looks quite healthy. I suspect *S. Hofmanni* of being likely to become as great a plague as *Digitalis ferruginea*, one plant of which last year has covered this rockery thickly all over with lusty seedlings, so I have pulled most of it up. *S. pendula* is much smaller and neater in growth, and hangs prettily over the edges of stones. *Dianthus superbus* has filled the whole garden with delicious scent, but now looks very untidy on a sunny rockery. It is worth having anywhere in a good mass for the sake of its spicy sweetness, that goes on for many weeks. *Convolvulus althæoides*, such a very pretty thing on account of its unique contrast or rather harmony, of deep pink flowers and silver leaves, has established itself too thoroughly on this same rockery, and sends up myriads of young plants, having an underground connexion often of surprising length with the parent. In time it will take the whole rockery, and the time will not be so long either, but it carefully marches sunwards. Spray Millet, or what looks exactly like it, though shorter in spray, has ripened, and that exquisite colour-gem among birds, Gould's grassfinch, or the gouldianfinch, of which I have an example as a pet, likes it very much, preferring it, indeed, to the well-seasoned sprays from the bird shop, upon which he is usually dependent.

There never, surely, was such a season for Groundsel. Our garden is thick with it, and as fast as one crop is hoed off, another appears. Some seedling Radishes, ineffectually netted by the man-of-all-work, who has the usual cottager's craze for home-saved seed, attracted many birds, chiefly greenfinches, but including some goldfinches, very rare in this garden as a rule. The green linnet seems to be a very incautious bird, clumsy at escape, for one of our shipperkes, who has a love for the sport of bird-hunting, has here killed a number of them, to the no small advantage of a large family of young ferrets with which we are at present blessed. This dog is so sharp that she can and did catch

an old thrush on the wing in the shrubberies, but the goldies are luckily much too nippy for her.

The only hardy Chrysanthemums that have lived through the winter, and, what is much worse, the spring, in the open, are the splendid Goacher's Crimson and Robbie Burns. Both are flowering well, but my three years' experience of this soil teaches me that it will be necessary yearly to plant all the sorts I want to be sure of in April. The hardy yellow, Carrié, was in flower in the middle of August. I have seen nothing but praise given to this Chrysanthemum, but I think its extreme earliness a fault rather than a virtue, and an unpleasant reminder of autumn. I have now no Dahlias but Pompons, as last year and the year before wind wrecked the Cactus and show varieties. The Pompons go down under days of fine misty rain, though they stand heavy downpours, but bear wind with equanimity. I got all the pink varieties I could hunt up, having a particular weakness for that colour, and many are extremely pleasing, but the jewel among all is Elizabeth, a small deeply quilled flower of a most beautiful and unique pure cherry colour. Its only fault is that its very stiff stalks are a trifle short at the beginning of the season, but later they lengthen.

BULBS IN THE MIXED BORDER.

BULBS have of late years become so popular for bedding purposes and for planting in grass swards that their value as border plants is in some danger of being overlooked. When used judiciously bulbs are a great acquisition to the ordinary mixed border. It must be admitted, however, that the free use of bulbs in such borders has its drawbacks, but, taking everything into consideration, the advantages undoubtedly far outweigh the disadvantages incurred. The beauty of a flower border where bulbs—I employ the term in its broadest sense—are freely used is maintained for a much longer period and the brilliancy and variety of colour at command are far greater than when only the so-called herbaceous and florist's plants are planted. The two greatest drawbacks with such a border are, first, the difficulty of digging and manuring it; and, secondly, the impossibility of rearranging it to any great extent without disturbing the border at a season—in August or early September—when many of the ordinary flowering plants are at their best. Such a radical overhaul is, however, only needed at rare intervals, and even then can be carried out without necessarily spoiling the whole appearance of the border. For several years past two of the most attractive borders in the gardens here have been those in which all kinds of bulbs have been freely planted among the commoner perennial, biennial, and annual flowering plants, and the result has in every way been highly satisfactory.

In planting such a border it is essential that the bulbs, and other plants flowering at the same period, should be distributed and arranged more or less equally throughout the border, so that one portion shall not be bright and another part dull and unattractive. Irregular and light, but not extensive, grouping of bulbs is advisable, as the best colour effects are thus obtained. Crown Imperials, Polyanthus Narcissi, florist's Tulips, Muscari and Chionodoxas, mixed in with Aubrietias, Double Arabis, Polyanthus, Primroses, and Daisies, and here and there a few Wallflowers, are the earliest flowering plants in such a border,

most of them commencing to make a show by the end of March. Following these come the May Tulips, Scillas, Fritillarias, and Ornithogalums. By the time the other non-bulbous spring-flowering plants are waning, Violas, Pinks, various species of Campanulas, and Erigerons are beginning to take their places. Spanish and English Iris, the Colvillei type of Gladiolus and the Camassias keep up a succession of bloom well into July and August, when the beauty of the border is upheld by Montbretias, Lilies, Galtonias, and the late-flowering Gladioli, and carried on by them until frost puts an end to outside flowers.

During the early summer and autumn herbaceous plants such as Delphiniums, Sun-flowers, Phloxes, and Anemones, biennials such as the Chimney Campanula and Foxgloves, hardy and half-hardy annuals such as Poppies, Godetias, Schizanthus, Nemesis, Alonsoas, Stocks, Asters, and such like all help to make the mixed border interesting and attractive. The annuals are planted in such places as where the early bulbs have died down, and where the spring-flowering plants like the Arabis, Polyanthus, Primroses, and Aubrietias have been removed to their summer quarters in the nursery ground. These latter, with the Gladioli and Iris, are the only perennials which are interfered with. All the other plants, bulbous or otherwise, are not disturbed from year to year, except when they show signs of overcrowding or the need of better soil.

W. W. PETTIGREW.

Superintendent of Parks, Cardiff.

NOTES ON HARDY PLANTS.

FUNKIA GRANDIFLORA.

FROM the point of view of flowers, this is the finest of all the Plantain Lilies. A large clump is now bearing over thirty bloom-scapes. The flowers are over 5 inches in length, and twenty or more are carried on the same scape, though only three or four are expanded at the same time. They exhale a delicious fragrance, and on this account are of great value for indoor decoration. It should be planted in a warm and sunny spot, or will probably fail to flower freely, a defect which has led to its cultivation being discontinued in some gardens. In shady situations, such as many of the other Plantain Lilies flourish in, it can hardly be expected to bloom well. Where it fails to bloom satisfactorily in the open it is well worth growing in a pot under glass for the sake of its scented flowers. It is also known as *F. subcordata* and *F. japonica*.

S. W. F.

ANTIRRHINUM GLUTINOSUM.

THIS modest little Soapdragon has given a great deal of pleasure in my garden during late summer, partly because it was unknown until sent by a friend, partly because it has fallen so well into its place on the top of the coign of a retaining wall, where it has run over the stone and is overflowing the edge in the happiest fashion. Still full of flower it seems likely to continue so for some time to come. *A. glutinosum* is very unlike a Soapdragon in habit, having long trailing stems, thick set with small alternate and velvet-smooth leaves, grey with the silky hairs which cover both upper and under surfaces. One cream-white flower with pencilled red lines on tube and upper lip is produced from each leaf-axil, and these look as if growing in pairs, as in the larger-flowering opposite-leaved *A. Asarina*, but this is not the case. The whole plant is somewhat sticky to the touch, as its name would imply, though not more so than in *A. Asarina*. Both of these trailing species are rather tender, *A. glutinosum* being Spanish and the other Italian, but they can be

treated with great success as half-hardy annuals. The Italian species is not new, as I remember it doing very well as a perennial rock plant on the dry chalk soil of a former garden. Both are valuable for walls or rock crevices. The foliage alone of *A. Asarina* makes it worth growing, for its strongly-nerved leaves with crenated edges have somewhat the character of Ground Ivy but for their silky coat and paler green, and the whole plant is charming, as it fits itself into the niches or joints of stonework. It does not, however, flower so freely, though its flowers are larger, nor spread so fast as *A. glutinosum*, which seems to be a plant of more recent introduction. K. L. D.

SOLLYA HETEROPHYLLA.

THE Australian Bluebell Creeper is often met with in the south-west, where it bears its drooping, Gentian blue blossoms for some months, and makes a pretty picture against a south wall, the numberless brightly-coloured flowers forming an azure mist. It is generally held to be very tender, but as I have seen it in vigorous health on high ground in the neighbourhood of Chepstow, where it received but the scantiest winter protection, it must be fairly hardy, at least as much so as the Myrtles, which flourish in the same locality. In cold districts it makes an excellent greenhouse climber. It rarely attains a greater height than 10 feet, but forms spreading masses on the walls. It seeds freely, the pods hanging on the plants through the winter. Young plants are readily raised from this seed, and will show flower in a year from seed-sowing. *Sollya parviflora* or *linearis*, formerly considered a distinct species, is now classed as a variety of *S. heterophylla*. S. W. FITZHERBERT.

THE DANDELION-LEAVED EVENING PRIMROSE.

(*ENOTHERA TARAXACIFOLIA*.)

This is one of the finest of that section of Evening Primroses characterised by a low, trailing growth and large blossoms of a white-pinkish or yellow colour, expanding fullest towards evening. The name (*E. taraxacifolia*) was at one time applied to (*E. acaulis*, a much inferior plant with smaller flowers, but, possibly, only a variety of the other. Both are quite hardy and perennial in light soils, but they often perish during winter on those that are wet and heavy. (*E. taraxacifolia* has a fine effect where planted in a rich, deep soil in the rock garden, where its trailing stems can droop over the ledge of a block of stone. The flowers vary from 2½ inches to 3½ inches across, and are pure white when first opened, but afterwards gradually change to a delicate pink. Other beautiful kinds are (*E. marginata*, (*E. missouriensis*, also called (*E. macrocarpa*, all of which require treating similarly to (*E. taraxacifolia*. (*E. speciosa*, which is a very handsome plant, grows from 1 foot to 1½ feet in height, and bears an abundance of large and delicate white blossoms. This plant is best grown in a border of rich light soil, where, if not disturbed, it will soon spread into a large tuft. (*E. taraxacifolia* is a Chilean species, but the others mentioned are natives of North America. G.

DIANTHUS DELTOIDES.

THIS charming little maiden Pink is a low-growing perennial, well adapted for the rock garden, as it will flourish in the poorest of soils. It, however, grows more luxuriantly with richer treatment, producing a long succession of its bright pink flowers. It is readily increased by means of cuttings, and self-sown

seedlings spring up freely round about plants that have flowered and ripened seeds. The plant shown in the illustration is a self-sown one, most happily situated on a rocky ledge, where it is seen to the best advantage. Common in some parts of this country, this species is usually found in rather dry gravelly pastures, where the grass does not get coarse enough to smother it. A suitable companion to the above is the variety *glaucula*, with white flowers, which is found growing on Arthur's Seat near Edinburgh. W. IRVING.

SILPHIUM LACINIATUM.

THIS is a representative of a group of American composites not generally found under cultivation, but it is a stately plant and a capital border subject. The leaves are Centaurea-like and finely pinnate, the stems somewhat gaunt, yet giving a distinct character to the plant. Several flowers are borne on each stem, and these occur at irregular intervals, but all face the west; even if produced on the eastern side of the stem they curve round. They are 3 inches to 4 inches across and are lemon yellow in colour, the disc being made up of lemon yellow florets, which drop away quickly, till on the third and fourth day of opening but few are left in the extreme centre. The calyx envelope is very stout and a trifle viscid. Its habit of facing westward must influence those who would plant this species, and one could suggest having a good clump in the herbaceous border with a background of dark greenery, so that its pretty leafage and really beautiful flowers might be displayed to good advantage. The flowers resemble *Helianthus* somewhat, but they are infinitely more refined. It flowers in August and September, and may grow 5 feet to 7 feet high. Many call it the "compass" plant. G. B. M.

DESMODIUM PENDULIFLORUM.

THIS is a remarkably handsome plant when well grown, resembling a dwarf and free *Laburnum* in its habit. It is a sub-shrubby plant, with arching and pendulous branches 4 feet to 5 feet long, and it appears to thrive well at the foot of a south wall, and it is seen at its best when raised above the

general level. A position on a raised bank or retaining wall, provided the site is warm, will suit it well. Its flowers are borne *Laburnum*-fashion in pendulous racemes, depending from every leaf-axil, and they are coloured a bright rosy purple, and generally thirty to fifty are contained in each raceme. These vary in length from 6 inches to 10 inches, and are often triple-branched. Very severe winters may cripple the plant for a time, but I have never known one to be killed outright if the position was a dry one. Grown in a border amidst other plants much of its beauty is lost. It is like the *Fuchsia*, requiring to be isolated and raised aloft to be fully appreciated. It flowers in August, September, and October. There need be no fear of drought harming the plant, for, like most *Leguminosæ*, its roots descend 3 feet deep. G. B. M.

WILD CROCUSES.

WHEN one considers the delightful effect produced by a large mass of these charming flowers, as seen in many a meadow in spring, it seems strange that they are not more freely used for naturalising in similar places. It is true that of late years they have been planted extensively in many public parks and gardens, chiefly forms of *C. vernus* and *C. aureus*. There are, however, several other species, both autumn and spring-flowering, that might with advantage be used for making charming pictures towards the end of September and beginning of October and in the early spring. There are some species which flower during the winter, thus connecting the autumn and spring-blooming plants.

These, however, do not develop their full beauty in the open ground, but require the protection of a frame, and thus are rarely met with except in botanic gardens, or in the gardens of enthusiasts. A few of the best for naturalising are, beginning with the

THE MAIDEN PINK (*DIANTHUS DELTOIDES*) SELF SOWN ON THE ROCK GARDEN AT KEW.

autumn-flowering species, and taking them in alphabetical order :

AUTUMN-FLOWERING CROCUSES.

C. asturicus.—A pretty species from the mountain of that name in Spain, with flowers ranging in colour from blue to lilac and dark purple.

C. hadriaticus.—A native of the Ionian Islands and Albania, with pure white flowers in some forms, while others are pencilled at the base with reddish lines, or richly suffused with violet.

C. iridiflorus.—Also known by the name of *C. byzantinus*. This is a very handsome plant, the flowers somewhat resembling those of an Iris, owing to the marked difference in size between the outer and inner segments. A native of Eastern Europe, the flowers are large and rich purple in colour.

C. longiflorus.—From South Italy, a charming species, with light purple flowers, yellow at the throat.

C. medius.—A beautiful species from the Riviera and the adjacent Maritime Alps. The flowers are bright purple, veined at the base, and the much-branched stigma is bright scarlet.

C. nudiflorus.—This pretty Pyrenean species is naturalised in the meadows near Nottingham, and in other Midland counties. It has large bluish purple flowers, and when established it spreads by means of stolon-like shoots which form independent corms.

C. pulchellus.—This species, with lavender-blue flowers, comes from Eastern Europe, where it grows in heathy thickets. It is very free-flowering, and an established clump produces a great number of flowers for a considerable time.

C. speciosus.—One, if not the handsomest, of the autumn-flowering species, this is also one of the best for growing in grass or for massing in borders or in the rock garden. It is a native of Asia Minor and adjoining countries, and has long been in cultivation. The flowers are of a rich bluish purple suffused with darker veins. Like most of the others there is more than one form of this species.

C. zonatus.—From the mountains of Cilicia, with rosy lilac flowers, having a yellow centre and an orange zone. This is a beautiful Crocus.

There are many more autumn-flowering species worthy of cultivation, but the above may be considered the best. The following is a selection of the best

SPRING-FLOWERING KINDS.

C. aureus.—A native of Eastern Europe and Western Asia Minor, with rich golden yellow flowers. There are several varieties of this with milky white, sulphur colour, and sulphur with crimson-brown markings on the outside of the segments.

C. biflorus.—The Scotch Crocus is a species of wide distribution, from Italy to Asia Minor. It embraces a number of distinct forms varying in colour and markings. In the typical plant the segments are white or pale lavender, feathered on the outer segments with purple markings. Other forms are a uniform pale lavender with orange base, *C. b. estriatus* and *C. b. Weldenii*, with either white flowers or white externally freckled with purple. There are also many others too numerous to mention here.

C. chrysanthus.—This is a very early-flowering species like the above, and is a native of Asia Minor. It varies very much in colour and in the markings on the outer segments. The chief varieties are *C. c. var. albidus*, *C. c. fusco-tinctus*, and *C. c. fusco-lineatus*.

C. Imperati.—From the neighbourhood of Naples, one of the first in flower, and very beautiful with lilac flowers and darker featherings; very variable.

C. Sieberi is bright purple, and comes from Greece. It is very attractive and very free flowering.

C. suaveolens.—A native of the country around Rome, has violet and fawn flowers with purple markings.

C. susianus, the Cloth of Gold Crocus, is a well-known plant with golden yellow flowers, striped or suffused with brown, and is very showy. It is a native of the Crimea, &c.

C. vernus.—The spring Crocus is a native of many parts of Europe, and is also naturalised in several parts of this country. The colour forms of this species are very numerous, ranging from pure white to deep purple.

C. versicolor.—Also with a great range of colouring from purple to white, the outer segments being variously marked and feathered. It is a native of Southern France and Italy.

The species enumerated above represent only a part of the genus Crocus, but with these one may have a succession of bloom from September to March.

W. IRVING.

THE FLOWER GARDEN.

ANNUAL AND BIENNIAL HAIRBELLS.

CAMPANULAS comprise annual, biennial, and perennial species—an interesting and beautiful family, adapted for all kinds of situations, and differing greatly in expression. The little *C. fragilis*, that spreads its growth over the rockwork, is different from the gay and gaudy Canterbury Bells. A rock garden well planted with the Bellflowers makes a mass of colour, which is obtained at little expense.

A very distinct section of the genus is that comprising the annual and biennial kinds. Annual flowers, we are afraid, have had a poor time this season, and where the rainfall has been slight since the spring the seedlings are making slow progress. We were looking at an important collection of Campanulas recently, and the annual kinds had scarcely moved; but they must not be judged from their behaviour in an unusually hot season, when everything is hanging its head in the bright sunshine. The most important annual species is *C. macrostyla*, which ranks amongst the finest of hardy annual flowers. It is remarkably distinct, possessing a character peculiarly its own and unlike all other members of the family. The habit of growth is rigid, and it grows about 1 foot high, whilst it assumes a candelabrum-like form, the much-branched, wiry stems embellished with very small leaves. One wants to see a good mass of it, and this applies to annuals in general. They are effective when in bold clumps or colonies. The distinguishing feature of this species is the style, hence the origin of the name, and it is remarkably developed, standing out erect from the flower, which is quite flat, salver-shaped, and the leaves and stem are ciliate. In the month of July this fine annual Campanula opens its handsome flowers, which are veined with blue on a white ground and shaded with purple. There is a variety named *rose-flora*, which, as suggested by the name, has rose-coloured flowers. One does not often see this Campanula in gardens, but it is worth growing for its distinct flowers. Another good annual one is *C. Loreyi* and its variety *alba*, which are pretty kinds, easily grown, and last almost throughout the season. *C. Loreyi*, sometimes spelt *Lorei*, has been long in English gardens. It is synonymous with *C. ramossissima*, and was introduced from Mount Baldi, in North Italy, in 1824. The plant grows about 1 foot in height, and has small shining leaves. The deep blue flowers are freely produced, and make a good show when one has a good mass of plants, as previously advised. This annual is not very common

in gardens, but it is worth a place in the border, especially where there are other kinds. There are varieties of *C. Loreyi*, and the chief is named *alba*, the flowers of which are greyish white, and also *C. l. fl. pl.*, besides a form called *stricta*, in allusion to the upright character of growth, the flowers light blue in colour. These are the best of the group, but a few others may be named. *C. Lœfflingii* is quite a dwarf species from Spain, where it colours the cornfields with its flowers, which are funnel-shaped, produced in panicles, and of a blue colour. It is useful for the rockery, but is very dwarf, only a few inches in height. A good patch of it is showy, and the seed is easily raised. We may add *C. strigosa* and others, but the most important have been described.

Many Campanulas may be treated as biennials, but the chief biennial kind is *C. Medium*, a favourite old plant that is superb in masses, owing to the varied and splendid colours. It is the most useful of the family, showy either in the border or in pots, and there is much diversity of character in the several varieties. Cross-fertilisation has done much, and amongst the large number of varieties are some very charming forms. We much prefer the ordinary singles to the duplex and double types. There are many good strains as they are called, and a mixed packet of seed will give many fine things. The plants bloom with the greatest freedom, each shoot heavily weighted with the stout bells, and when in perfection are perfect mounds of blossom. One need not describe such a lovely subject, which should be in every good garden, grown in masses to get effect from the flowers. Another point is that the plants even when in bloom may be lifted and potted for the greenhouse, conservatory, or to form groups in the house or at the exhibition. The calycanthema varieties are those in which the calyx has by selection assumed a very broad saucer-like character, and it is this type that gets coarse when too large, wanting in the refinement and beauty of the ordinary forms. The plants, it must not be forgotten, should be put into bold groups in large gardens, and the effect is finer if the colours are kept distinct, not mixed, these being very poor in comparison. Get a good blue, rose, purple, white, and try grouping them in distinct colonies, and we think that the result will be pleasing. There are plenty to select from, the colours varying greatly, and the seed is easily raised. Keep the fading flowers picked off to promote continuous blooming. Get the young seedlings in position before autumn is far advanced. A succession of seedlings should be obtained, otherwise there will be a blank in the display.

C. persicifolia, *C. pyramidalis* and their respective varieties, besides many others, especially the trailing kinds, may be mentioned; but these have been often noted in THE GARDEN. Of biennials, the Canterbury Bells hold first place, and the interesting annual kinds add to the beauty of the garden in the summer months.

BEDDING VIOLAS AT CAMBERWELL.

To see these hardy, free-blooming plants in gardens generally is common enough, but to find them presenting a wealth of bloom in a densely-populated district such as South London is certainly not an everyday experience. There is at Camberwell an area of some fourteen acres that originally formed part of the famous Myatt's Market-field Gardens. The land and a large area surrounding it came into the possession of a Mr. Minett, and in laying it out as a huge building estate he generously gave these fourteen acres to the local authority to be a public park for all time. That area is under the control of that able administrative body the London County Council, and its present superintendent is Mr. Frank Wright. He has made liberal use of Violas, and even now, at the fag-end of the season, great quantities of them can be seen blooming profusely. There are edgings of William Neil, Ardwell Gem, and others from 15 inches to 18 inches broad, almost masses of bloom, and very charming they are. The chief white, very pure and good, is *Niphetos*; Bridgegroom, a delicately tinted mauve; *Duchess of Fife*, edged blue; *Walter Welch*, clear yellow;

Dulwich Park, bright yellow with small dark eye; J. B. Riding, reddish mauve; Blue King, True Blue, and several others. None are left outdoors for stock during the winter. Propagation by cuttings in frames commences at once, and these, as well-rooted plants, are put out largely in the spring.

It is interesting to see here what fine plants seedling Marvel of Peru in variety grow to be, also to observe the free use made of that fine old plant *Ageratum mexicanum*. There is also a singularly free and beautiful double-fringed

that a crumb of bread cannot lie on the gravel walk five minutes undiscovered, small pests flourish to an extent that makes it almost hopeless to grow some kinds of flowers which earwigs and slugs specially affect, while there are no trees so riddled with caterpillars and infested with blight as those of sparrow-ridden suburbs. In the country the sparrow becomes more merged among the general bird-life of a garden, and it is only in cases of conspicuous wrong-doing, such as tearing to pieces Crocuses

weed-seeds birds may do more harm than good by reducing the stress of the struggle for existence between the weeds themselves. If you watch a skilled gardener thinning out his seedlings, you are apt—if you are no gardener yourself—to be amazed at the waste of half-a-dozen healthy young plants for each one allowed to remain; and the only difference in the farmer's treatment of his weeds and of his Turnips seems to be that, whereas he tries to hoe up all the weeds he merely hoes up five

A GROUPING OF THE WHITE LILY (*LILIAM CANDIDUM*).

Petunia which originated in the park, rosy magenta, edged white, named Camberwell Beauty. This is one of the best yet raised. A. D.

THE MADONNA LILY.

PICTURES of the Madonna Lily never weary, so we make no apology for publishing the accompanying beautiful illustration, which we are able to do through the courtesy of Messrs. Webb and Sons, Wordsley, Stourbridge. It is rarely that one sees such a splendid group of the white Lily, but what could be more attractive in early summer? It is worth remembering that there are two distinct forms of *Lilium candidum*—the poor or starry-petalled form and the good or broad-petalled variety, and the latter should be planted. It is needless almost to repeat the oft-expressed injunction to leave the bulbs of the white Lily undisturbed. The best advice the cottager, in whose garden they luxuriate, can give is "to leave them alone."

ROUND ABOUT A GARDEN.

THE SPARROW QUESTION.

ONE is often asked—indeed, one often asks one's self—whether sparrows do more harm than good in a garden; and perhaps the answer depends more upon the temperament of the answerer than upon the proved facts of the case. Certainly their utility in exterminating "noxious insects," &c., cannot be large, because in a London back garden, so thoroughly patrolled all day by reconnoitring sparrows,

or Primroses which grow in the open—those which grow in the shade of shrubberies are attacked by the greenfinch instead—that we can differentiate the sparrow's work at all. This, some say, leads us to take an unfair and jaundiced view of the sparrow in general; and they ask us to admire its utility in "keeping down the weeds."

BIRDS AND WEEDS.

It is at this time of the year, after the harvest has been cleared from the land, that the sparrows do most to justify the arguments of those who defend them as useful enemies of the weeds. You have only to watch the flocks of sparrows in the empty fields for a few minutes to see that they are waging ceaseless war upon the weeds. There is a large Clover-stubble here, in one corner of which a stack stood last year; and on the rank ground where the stack was a matted growth of Knot-weed covers the ground. Here large flocks of sparrows seem to feed all day, and the crop of one that was shot contained several hundred seeds of weeds and only one grain of damaged Barley, which the bird had probably picked up from the adjoining cart-road. It would be easy, by multiplying the hundreds of sparrows feeding at that spot by the hundreds of weed-seeds which each consumes daily to arrive at truly stupendous totals of the "good work" done by sparrows in a year. But I always look at figures thus obtained with an eye of doubt. So far as any patch of ground which I know in this sparrow-infested country is concerned, there are always more than enough weeds waiting to choke it up every year. If there were not a sparrow in the land the standing weed-crop of waste land could not be heavier than it is. Indeed, it is quite possible that by destroying

out of every six Turnips to leave room for each sixth one to grow. If, then, the gardener and the farmer deliberately destroy from 60 to 80 per cent. of their seedlings in order to get a maximum crop, may not the birds which assemble to eat the seeds of weeds be helping them rather than otherwise?

THE BALANCE OF NATURE.

Of course, in a state of Nature, where every species of plant is fighting desperately against its neighbours, the birds may decide the issue of the struggle against those kinds of plants whose seeds they devour; but I shall believe that the birds do good to the farmer in keeping down weeds when I see a field which, after being left to itself and the birds' kind services, does not bear a full crop of weeds all the same. I have not seen such a field yet. The fact is that the birds and the plants have grown up together through all the ages and thoroughly understand each other, so to speak. The plants know no way of saving all their seed from the birds, and the birds cannot eat all the seeds that the plants produce; but when man ploughs up the land with the idea of filling it only with grain for his own consumption, both the weeds and the birds hasten to take advantage of the disturbance thus caused in the balance of Nature.

ALLIES AGAINST MAN.

First of all the birds eat the worms and grubs which are turned up—and if the sparrow took his proper share in this work, following the plough like the rooks and gulls and starlings we might admit that he was doing good. Next, the birds try to eat as many as they can find of the seeds which man puts into the land—and in this the sparrow is only too energetic. Afterwards it is the turn of the weeds, which

hasten to fill up as much of the ground as possible before the crop gets under weigh. During this stage the birds are inactive spectators of the struggle between man and the weeds; but when it is all over and the crop is ripening they come and help themselves to it freely, in spite of man's watchers and scarecrows. Later, when the crop has been harvested and the weeds are seeding freely, the sparrows are certainly ringleaders of the mobs of birds which come to eat the field-seeds; but, as I have said, the net result of their voracity is not appreciable in the discouragement of weeds. There are certain crops which, as every farmer knows, leave the land in a shockingly weedy state, but this is not because the birds cannot help to keep down the weeds, but because the farmer cannot hoe them effectively. No, for all the good which birds do in keeping down weeds—although at this season they may eat little else than weed-seeds—I believe that all the sparrows in the country might die tomorrow and agriculture not be a penny the worse.

THE SPARROW'S AGGRAVATION.

It is, however, equally easy to exaggerate the harm which sparrows are supposed to do to agriculture, and even the farmer can afford a smile at the estimated "millions of tons of wheat" debited to the sparrow's account in

Britain by statistical pessimists. In a garden, however, which is created mainly for pleasure, it is aggravation rather than loss which counts, and the sparrow is past-master in the art of aggravating. In spring it is especially hard to keep one's kindly feelings towards wild life at large intact towards the sparrow, when you watch the self-satisfied and perky air with which he pulls to pieces an early clump of flowers, chucking a mutilated blossom on the ground with every jerk of his beak. No doubt you can keep him away from cherished plants by playing upon his fears with stretched threads of black cotton, to which some people attach bits of paper or hens' feathers as an extra bogey; but in these utilitarian devices there is something which clashes so much with the unruffled pleasure which one seeks in a garden that one would rather have no flowers at all than see them protected with hens' feathers on strings. Perhaps it is a personal twist of character, but to know that a clump of Primroses in the open is protected from the sparrows by black cotton, even if I cannot see it, detracts greatly from the pleasure of it. Perhaps the reason is that in our gardens we aim at a complete and perfect triumph over Nature, and we resent the black cotton as unwilling tribute paid to the power of the sparrow, one of Nature's homeliest underlings. E. K. R.

BLUE - FLOWERED BULBS OF SPRING.

IF an average of colours in the flowers of any given district were taken, it would probably be found that the percentage of white-flowered plants would be the largest, the next would be yellow, then red, and at the end of the list would come blue and violet in much reduced proportion. There are reasons for all things, and we are taught to believe that the colours of flowers are given to them mainly for the attraction of insects, which are amongst the principal agents in their fertilisation. We poor humans, it seems, with all our predilections for colour and scent and form, are of no account in this part of the great scheme of Nature. Moreover, blue flowers prevail mostly in spring, and it has been suggested that since blue is not a conspicuous colour, it shows better against a background of fallen leaves and brown earth than in a setting of too vivid green. To be conspicuous, then, is apparently one chief aim of flower-life, but let us hope that we need not accept every theory advanced by learned professors as final, to the uprooting of some of the most cherished of our old-world fancies. Whatever attraction blue flowers may possess

THE APENNINE WINDFLOWER (ANEMONE APENNINA) AT FOOT OF TREES. (From a photograph by Miss Willmott.)

for the insect tribe, there is no doubt that they have a peculiar fascination for human eyes, perhaps by very reason of their greater scarcity, and at this season, when we ought to be making provision for next year's garden, it is well to con over in our minds both our requirements and the possibilities within our reach. Nearly all the blue-flowering bulbs and tubers of early spring are what we may call carpeting plants, though not of the carpet-bedding order. Many of them, like our native Bluebell or the Apennine Anemone, which we may have seen in its natural habitats, will spread, as it were, into wide lakes and pools of shimmering colour, hiding the brown earth strewn still with the tawny withered leaves of autumn, and looking, from afar, like the blue of heaven reflected on the unruffled surface of quiet waters. So if we cannot dip our plumb-line into the depths of her mysteries, we may at least take garden lessons from Nature, who colonises her subjects and seldom isolates them. It is far better, as a rule, to mass one or two kinds of plants which fit well into their allotted position than to put in dribblets of many kinds here and there.

Blue is a sadly indefinite term. In fact, if some able and trustworthy personage in authority would take in hand to settle the vexed question of flower colours in general, it would be a charitable deed. At present violet and lavender and purple, with their multitude of intermediate shades, do duty for blue in many descriptive lists, often to the great perplexity of the intending grower. A fair proportion of spring bulbs, however, *e.g.*, Chionodoxas, Scillas, some small species of Hyacinths, and Muscari may safely be called blue.

CHIONODOXAS

are so well known and so readily multiplied, both by offsets and seed, that there need be little difficulty in colonising them where there is room. It is not generally taken into consideration that these bulbs may be planted 6 inches deep or more without detriment. They will take care of themselves and flower all the more strongly. This is a fact to remember when a "drift" is in contemplation in a perennial border, as the bulbs, which are small, are then less liable to be forked out or disturbed. It is also a good plan in such a position to put over them some spreading but rather thin-growing plant—*Campanula pusilla* is as suitable as any—so that the Chionodoxas may pierce through the green carpet and their flowers keep free from contact with the wet soil. In time they disappear, but their place is taken later on by the dainty little Hairbell. Grown in masses Chionodoxas are amongst the most precious, as they are the most easily established, of our earliest blue spring flowers, and where it is possible to plant them in grass which is not too thick and abundant they are quite at home. The more we can naturalise such delightful hardy bulbs as Chionodoxas and Scillas the better. The first of the

SCILLAS

to flower, coming with the earliest Snowdrops, is the well-known *Scilla sibirica*, and the latest of the spring-flowering species, *S. peruviana*, pushes up its broad, conical heads of deep blue in May—an old-fashioned flower this, not very often met with now, for we are too fond of pulling our garden arrangements to pieces and remodelling them to suit its constitution, but where it can be left alone for a reasonable time it is extremely handsome. To come to flowers of a rarer description, some of the dwarf forms of

BULBOUS IRIS

may be allowed to fulfil our restriction of colour, such as *I. histrioides*, the new *I. wilmottiana*, and, possibly, the slate blue *I. sindjarensis*, but here again opinions may differ. It was my lot once, and only once, to see a very lovely blue Iris belonging to this section, which was labelled *I. Vartani*. Whether it was true to name or not, the flower itself was too beautiful ever to be forgotten. These rarer bulbs are too precious to be played with in the open, and seem to demand frame and cold greenhouse culture, at any rate for the present. There can be no divergence of opinion as to the claims of the beautiful

CHILIAN CROCUS

(*Tecophilaea cyanocrocus*) to head the list of pure blue spring-flowering bulbs. It is instructive to look back at the history of this lovely plant. At first it was coddled almost to death, but Herr Max Leichtlin, who took it in hand and through whom it seems first to have found its way into English gardens, soon discovered that heat was not what it wanted. It has since those days passed through various phases of frame and cool house culture, and it seems to be an established fact that it is quite safe out of doors if planted deeply in dry, sandy soil in a suitable aspect. It is not new, having been figured in these pages as long ago as 1881, yet where is the garden in which the Chilean Crocus is a familiar flower! Let us hope that it may not be long before this charming bulb, with its exquisite flowers of gentian blue, becomes acclimatised with us, at least in some favoured spots. As it is it may be commended to all real lovers of plants as worthy of their best endeavours, for even a bulb or two will give a sufficient number of well-lasting flowers to afford the keenest pleasure. Cultural notes from those who have been successful in its treatment would be both interesting and acceptable to intending purchasers.

A short list is added for the convenience of those who in their autumn planting wish to be reminded of pure blue or blue and white flowering bulbs for the spring garden, though with the utmost care it is not easy to lay down a hard and fast rule as to what is and what is not true blue.

THE AURICULA IN OCTOBER.

THE Auricula now prepares itself for the winter season. Towards the end of the month the plants can be removed to their winter quarters—frames facing south or the Auricula house, where they can remain through the next blooming season. They will now require less water as the air contains more at this season, and the heavy dews expected at this time of the year also increase the supply of moisture, but care must be taken that water does not lodge in the heart of the plant, as it may cause decay to set in and kill it. Watering only should be done when the air is mild and the wind southward.

If the surface soil has been encrusted by rain, damp, or stagnated air, stir lightly with a

pointed stick, and at the same time remove any decayed leaves. Continue to give as much air as possible both by night and day.

Bishop's Stortford.

WILLIAM SMITH.

THE FRUIT GARDEN.

APPLE BEAUTY OF BATH.

ALTHOUGH we have an ample choice in first early ripening Apples, some of them carrying rich colour, yet we seem to have none that produces such pretty fruit as Beauty of Bath. It was shown in very fine form by Messrs. Bunyard and Co., Maidstone, and by Messrs. Cannell and Sons, Swanley, at a recent meeting of the Royal Horticultural Society. Its free cropping qualities, beauty, and general excellence should make it soon become a popular early market Apple. It seems this year to be ready quite as early as Mr. Gladstone, to which it is an admirable companion. Miller's Seedling, a little-known early Apple, was also in the Maidstone collection. It succeeds the others very well. Red Quarrenden, Irish Peach, and Worcester Pearmain make up an excellent selection of early Apples.

A. D.

APRICOT MOOR PARK.

WHEN Mr. J. Crook recently exhibited a dish of very fine fruits of this old and meritorious Apricot at the Horticultural Hall before the fruit committee, it was remarked that old and good as the variety is—indeed, it is yet the best in cultivation—it has never had any certificate given to it. It was thought it might be regarded as absurd to do so now, although during the past few years some good old things have been so honoured. The only Apricot to which there is any record of a certificate being granted is one named Frogmore Early, the award being made as long ago as 1875. Moor Park is believed to have been introduced from the Netherlands about 150 years ago, and was first planted at Moor Park, hence its name. The failure of the variety, so noticeable still, of having branches which suddenly die, was seen and commented upon seventy years ago.

A. D.

RASPBERRIES AND STRAWBERRIES IN AUTUMN.

THESE fruits, so well known and so much appreciated in the summer season, have not, until within the past year or two, been duly recognised for regular supplies in the autumn. My object in detailing our mode of procedure at Gunnersbury is to encourage and extend their cultivation for autumnal supplies.

RASPBERRIES.

Cultivation, Soil, &c.—In this respect there is no deviation from that given to the summer-fruited varieties. Where the one thrives well, there also will the other succeed. It is advisable, however, to avoid a shaded position, all the light possible being needed to mature the fruits as autumn sets in, and likewise to guard against decay during damp weather. It is well, therefore, to select as open a spot as can be chosen; if facing the south or south-west so much the better, in order to secure as much benefit from the sunshine as can then be had. Avoid a heavy, retentive soil—this may be conducive to growth, perhaps, in some instances, but not to the maturing of the fruit. The rows should run due north and south when it can be so arranged. In our own case it is the reverse, but I should prefer it otherwise. The rows should be 6 feet apart in order to allow plenty of room for the circulation of air and for light between the rows. During the winter a dressing of farmyard manure is applied and lightly forked in, but should the growth be luxuriant this may be dispensed with in alternate seasons, a dressing of lime being substituted. When the ground is being dug over all the suckers that have run out are carefully removed. These Raspberries

are more disposed to throw out suckers than the summer-fruiting varieties.

Pruning, &c.—These Raspberries fruit upon the young wood of the current season, therefore the pruning is merely a matter of cutting down to the ground line. I do not advise this to be done, however, too early, otherwise the young growths will be correspondingly early and therefore liable to be cut off by late spring frosts. (Even with this safeguard we were caught in April, 1903, when severe frosts ensued, and the growths were thus thrown back for fully a fortnight.) If pruned by the middle of March no time will be lost. About every third year it is a good plan to replant all, or, say, do one-third of the stock every year. This will allow of the ground being thoroughly trenched three spits deep, and for a liberal application of manure. In planting afresh select the strongest stools only, casting aside all the weak ones. A good distance is 6 feet between the rows; there is no gain in planting closer, and in the rows it will be, say, 4 feet from stool to stool. The growths are allowed to come away in a natural manner, only the very weakest should be thinned out, no tying being done until it is seen that there are a sufficient number of shoots showing for fruit. This will be during the earlier part of August or possibly by the end of July in some instances. Then, if there are too many shoots to tie up, those

without any fruit are cut out to allow room for those with fruit. (I might add here that our crop was late in showing this season, hence it was the end of August before we had finished thinning and tying.) The shoots should be tied erect or as nearly so as possible. Our plan is to tie in a continuous line rather than in groups. By means of Bamboos a light trellis is made, to which the shoots are secured, a good plan being to sling each shoot separately, if not too long, to the Bamboo next above, the longer ones being first tied to the same Bamboo. Thus the one does not shade the other. Careful tying up prevents injury to the fruits during strong winds and gales. The first picking generally commences early in September in sufficient quantity to keep up a supply. It continues generally until the end of October. Last year (1902) we picked good dishes up to the middle of November, but that is an exceptional instance, I think. This season, 1903, there is promise of a late picking too, if the early frosts are not too severe. Protection is afforded against the depredations of birds by covering over the entire quarter with netting. For this we use nets made upon the square mesh (1-inch mesh) rather than use the old fish netting, which does not cover nearly so well. Towards the end of October, if there are still sufficient fruits left to ripen, it will be found a good plan to cover over with an additional net to protect from frost. It is surprising how much frost one net will keep off; two, therefore, will be more effectual.

Varieties.—The old October Red is still a good variety to grow for a late crop. The growth is somewhat short and stocky, the fruits of medium size. Belle de Fontenay is a better variety for general cultivation than the preceding, coming into bearing earlier, the fruits being larger and the growth stronger. We have also another variety, of which I do not know the name thus far (it was sent from France without a name attached). This is the finest in every sense, a robust grower, and one that fruits abundantly. It comes into bearing rather later than the preceding. We also grow a yellow variety, Surprise d'Automne, but this, so far, has not had a sufficient trial to be able to speak of it with any confidence. In addition there is the new variety first shown by Messrs. James Veitch last autumn; this I have not grown yet at Gunnersbury.

Uses.—We find that the autumn Raspberries are in great demand in the kitchen and stillroom for various purposes. As an addition to the dessert they are also welcomed when well ripened.—J. HUDSON, in the Journal of the Horticultural Society (1904). Reprinted by permission.

NOVEL POTATO CULTURE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The so-called novel Potato culture is a century old if it is a day. My father, who worked in market gardens round London over sixty years ago, has more than once described to me this method of obtaining young Potatoes. Some market growers practised it on quite a large scale. In some instances sheds were used, but any spare frames were employed, the tubers being just covered with light soil and then thickly covered with straw. I believe that this system was still in use about thirty years ago, but the immense number of new

LILIAM SULPHUREUM IN A RICHMOND (SURREY) GARDEN.

Potatoes grown in the Channel Islands in unheated glass houses killed it. Some years ago I had occasion to buy some Potatoes in the autumn. What they were I could never determine, but they were absolutely uneatable. They were put under a bench in a shed and were forgotten. I think it was in June that the shed was cleaned out, and to our great surprise this heap of old Potatoes had become a heap of new ones, and very nice they were.

J. CORNHILL.

LILIAM SULPHUREUM IN A SMALL GARDEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—When first introduced into this country the Himalayan Liliums were treated as cool greenhouse plants, as they succeeded indifferently out of doors. However, L. Henryi has since proved to be quite hardy, and to flower as freely outside as inside. Judging from the way L. sulphureum is flowering in a little front garden at Richmond it will do quite as well. Five years ago Mr. Corrin, the proud grower of the Liliums, planted a few bulbils, seven of which grew. No special treatment was accorded them beyond mixing a little lime rubble,

sand, and fowl manure with the ordinary garden soil. The first three years only growth was made, and Mr. Corrin felt disposed to pull them out, but fortunately left them for another year, when two or three flowered. This year (the fifth) all are flowering, six of the bulbils carrying three flowers each and the seventh one. The plants are about 5 feet 9 inches in height. Growing within a couple of yards of the road a few flowers were stolen last year, and to prevent them being seen the Privet hedge has been allowed to grow up, quite hiding them from passers-by. The ground at the base is quite thick with young plants grown from last year's bulbils.

A. O.

FUCHSIA MME. CORNELISSON.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I think that the memory of your correspondent "R. D." (page 167) has played him false in connexion with this Fuchsia, and that Mr. Burbidge is right as to the date of its introduction. My reasons for so thinking are these: In a catalogue of new plants for the spring of 1857, issued by the then prominent nursery firm of William Rollisson and Sons of Tooting, now before me, only one Fuchsia with a white corolla is mentioned, viz., Princess of Prussia. Next, on referring to a catalogue of plants grown by John Salter, Versailles Nursery, Hammersmith,

for the spring of 1861, the variety just alluded to, Princess of Prussia, and that spoken of by "R. D.," Queen Victoria (Story) are both quoted at the lowest price of any Fuchsia, viz., 1s. each, whereas Mme. Cornelisson is priced at 3s. 6d. This would certainly indicate that Mme. Cornelisson was of more recent date than the other two; in fact, if priced at half a guinea the first season, which was the usual price for new Fuchsias in those days, the second year 3s. 6d. is a very probable price. Some of these old catalogues are most interesting reading, for in announcing their new Fuchsia Princess of Prussia (Smith), Messrs. Rollisson quote an extract from the *Gardeners' Chronicle* as follows: "Among the recent novelties at the Regent's Park exhibition the best Fuchsia with white corolla we have ever seen was exhibited, the flowers being of good size, the white pure, and the blossoms produced in great abundance; it was called Princess of Prussia." I well remember a large specimen of this variety in the Temperate house at Kew when that structure was first planted, and it used at that time to attract considerable attention. Among the varieties distributed

by Rollisson in the spring of 1857 were two that enjoyed a good deal of popularity for years; indeed, one, Rose of Castile (Banks), still remains a favourite. The other, Guiding Star, was one of the most symmetrical flowers I have ever met with. A notable feature of those far-off times was the prices asked for most plants, prices which the nurseryman of to-day might ask in vain. Thus the show Pelargoniums raised by Beck, Dobson, Foster, Hoyle, and Turner were quoted at a guinea and a half, one guinea, and 15s. each. Perhaps the greatest contrast with the present time is evidenced by the prices of Begonia Rex, two guineas, and Cypripedium fairieanum, three and five guineas each. Now the Begonia can be bought for a few pence, whereas the Cypripedium is to-day almost priceless.

T.

VALLOTA PURPUREA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Before paying a recent visit to Messrs. Sutton and Sons' new range of glass houses at Reading I was quite in accord with your correspondent, P. Leonard Bastin, on page 196, as to his treatment of the Scarborough Lily. There I saw

two batches of recently-potted bulbs flowering most profusely. Each group consisted of about fifty plants in 5-inch pots. Some of the bulbs had two spikes of flowers. On an average each spike carried six to eight flowers. The blaze of colour produced by 100 spikes of this plant was gorgeous. The bulbs were exceptionally large, and I attribute their flowering so freely to their being well ripened. This may be the cause of so many failures with this plant, as after flowering the bulbs are often put aside to make room for some other plant coming into flower and given no special treatment till it is time for the flowering spikes to make their appearance the following year. A. OSBORN.

SOME GOOD VARIETIES OF MIGNONETTE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Some people are under an impression that there is little difference between varieties of Mignonette, and think one as good as another. But this is not so. I grow several sorts side by side so that they can be compared. The seeds were sown in pots in May, and planted out undisturbed into the open border early in July, where they made rapid growth, producing, from early in August till destroyed by frost, splendid blooms. Nothing is more useful to cut from during autumn, as the rain and damp do not spoil it. When sown early it gets tall and weak. Among highly coloured sorts I like Golden Queen, and when a good strain can be had the bright colours are most attractive. When used alone for filling a vase it is seen to great advantage. When the varieties are mixed Mignonette is not seen at its best. I have used this with good effect on a dinner table associated with other flowers. This sort is difficult to obtain true. This year I had seed from three different growers, and only one lot was true. As a compact growing kind of a whitish tint I can find nothing to equal Mile's Hybrid Spiral. For pot culture or the open ground it is equally good. This is the only one I grow for pot culture. Machet is very fine in pots when used for filling window boxes, &c. In spring this variety is sold extensively in the market, and is shown well at the Temple show. It is not branching enough to cut from, although the spikes are very large. If a reddish coloured Mignonette is wanted, then a good strain of Giant Crimson can hardly be surpassed. As a white sort I have seen nothing to equal Parson's White. Many years ago when first sent out the strain was grand and a free grower. For fragrance I think none is better than the common Mignonette. J. CROOK.

VEITCH'S AUTUMN GIANT CAULIFLOWER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I notice in THE GARDEN, page 199, Mr. T. B. Field recommends sowing the above Cauliflower about this date for wintering in cold frames and planting out in spring. Last year I had about 200 plants of this variety, and the same number of Early London, under the same treatment as advised by Mr. Field, but am sorry to say 90 per cent. of Autumn Giant went blind after they had been planted out and were a good size, whilst of Early London not one went blind and the crop produced was first-rate. The seed of Autumn Giant was from the same packet as that from which I am now cutting good heads. I am anxious to know if anyone else has ever experienced the same with this Cauliflower.

Rug Gardens, Corwen.

J. S. HIGGINS.

A SEEDLING MUSA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I enclose a photograph of a seedling Banana, which I think has made a rather remarkable growth. The seed was sown the last week in January, but there was no sign of germination at the end of April. I took up the seed and gave it several sharp knocks with a hammer, which apparently made no impression. I put it back, and the seedling appeared above the surface three days afterwards. During the first month it made

very little progress, but since then it has grown rapidly and is now 8 feet 9 inches high. I had to cut off three bottom leaves as they were damaged.

JAMES HUTCHISON.

The Gardens, Broomend, Aberdeenshire.

FLOWERS IN WEST SURREY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This season has been remarkable in the West Surrey garden of Clare Lodge, Rowledge, for the luxuriant growth and blossoming of several plants not usually seen in English gardens. Firstly, in the spring, the Australian *Acacia dealbata*, already as high as the chimneys of the south-west gable against which it is loosely trained, had a profusion of its yellow silky blossoms, reminding one of the Italian Riviera; since then *Desfontainia spinosa*, *Eucryphia pinnatifolia*, *Tecomas*, a hardy Orange, and hardy *Abutilon*, Pomegranate, white Indian *Azalea*, *Camellias* red and white, *Grevilleas*, *Azara*, and a white *Passion Flower* have flowered.

Finally, on the 19th ult., a variety of *Banana* (*Musa*) was opening its fourth whorl of flowers and fruit, and, as far as I know, is the only specimen of this plant which has fruited out of doors in this district. The fruit is still very small, and I fear will not attain perfection unless we have a rare continuance of dry sunny weather. The *Banana* has been out four winters protected by Bracken, and is now somewhat spoiled by a high wind of a week or two ago which tore the handsome leaves.

The fruit stalk comes from the main stem at the height of 5 feet 8 inches from the ground. The tips of the leaves reach to 9 feet in height.

WILLIAM TIDY.

The Gardens, Clare Lodge, Rowledge, Farnham.

LADY SUDELEY APPLE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Of all the Apples which have come under my notice none have been more satisfactory than the Lady Sudeley variety for present use. It is the most highly coloured Apple I know of at the present time. Its flavour is first-rate, its size is above the average as a dessert fruit, but not too large. The tree is vigorous but not unduly so. It appears to succeed either on the seedling Apple or the Paradise stock. Moderate pruning should be observed. I do not think it is a tree which will

SEEDLING MUSA.

Height, 8 feet 9 inches; from seed that germinated five months ago.

bear severe pruning, as I notice many of the growths are terminated by a flower-bud, and this is generally indicative of moderation in pruning. It makes one of the most shapely bushes or pyramids one could desire. The growth has an upward tendency, but not too much so, consequently the tree assumes an open appearance when it is moderately pruned. I am trying it as a trained tree, and at present it bids fair to be a success. This season the fruit began to

EARLY TULIPS.

ripen about the third week in August, and we finished gathering by the end of the second week in September. The fruit is best eaten as gathered, and being soft it soon becomes mealy if placed in a fruit room. Its appearance suggests that it would make an excellent market fruit. There is another fine Apple which is often overlooked, viz., *Gravenstein*. It is not so imposing as the above, but of really good quality, and is ripe a little time after Lady Sudeley, and before Worcester Pearmain. The flavour is crisp and pleasant. When the fruit is well exposed to the sun it takes on a bright patch of colour on the sunny side, while the general colour is bright yellow or gold. This Apple is a better keeper than Lady Sudeley. The stock on which this Apple is grown will influence its colour and flavour considerably. It is grown here on the Paradise as well as on the free stock, and the difference in the colour, flavour, and time of ripening is most marked.

Cirencester House Gardens.

A.

EARLY TULIPS IN LINCOLNSHIRE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I send you a photograph showing one phase of bulb culture in Lincolnshire—that of growing early Tulips under glass for the London markets. The picture gives some idea of the immense number of bulbs grown; they are usually planted in boxes.

Lincs.

H. W. J.

PLANTS THAT NEED CAREFUL HANDLING.

(Continued from page 215.)

CONIFERÆ.

(16.) *THUJA DOUGLASSII*, Carr.—“A curious case of a woman being poisoned by handling the branches and leaves of this tree while gardening is recorded by Neudorffer in the *Centralb. f. Innere Medicin.** The symptoms were spasmodic convulsions, dyspnoea, and coma. Other persons appear to have been more or less affected who were working at the same employment. It appears probable, therefore, that

* *Nouv. Rem.*, 1903, 65. Quoted in *Pharmaceutical Journal*, March 21, 1903, a e 122

the tree, which is cultivated for ornamental purposes, contains some poisonous ingredient to which some persons are more susceptible than others."

I admit this plant to the present list with doubt. But attention should be widely drawn to such a well-known tree in order that we may ascertain what are the real facts of the danger of handling it.

LILIACEÆ.

(17.) *Hyacinthus orientalis*, Linn., and varieties. (The common Hyacinth of gardens.)—"Forms of eczema* were said to have been produced in persons handling and cleaning these bulbs. Although the fact was familiar to gardeners, the cause did not appear to have been clearly traced. Experiments and observations at the Jodrell Laboratory, at Kew, had shown that both dry and moist scales were capable of producing considerable irritation in certain cases when applied directly to the skin. There was little doubt that the raphides were the prime agents. These needle-shaped crystals (composed of oxalate of lime) varied from 1-100th to 1-200th of an inch in length, and were arranged in close bundles, easily dispersed by rubbing the dry scales. In the growing plants they were doubtless protective, as snails, for instance, avoided Hyacinth bulbs, but attacked others growing close by. Roman Hyacinths (var. *albus*) were understood to cause greater irritation than other varieties."

Dr. D. H. Scott described some experiments which he had tried, tending to confirm the conclusion that the irritation of the skin produced by contact with the bulb scales of Hyacinths is due immediately to puncture by the numerous raphides."

AROIDÆÆ.

(18.) *Richardia æthiopica*, Spreng. "Lily of the Nile" (of gardeners); the common "Arum Lily" of Australian gardens.

Mr. J. Y. Johnson,† of Funchal, Madeira, shows that this plant is, like *Hyacinthus*, responsible for a form of eczema.

The laundresses of Funchal had tried to utilise the starch obtainable from the corms, but complained of the irritation in the hands produced by it, which, on examination, was found to result from the presence of numerous needle-shaped raphides.

Dr. Dickenson remarked that many of the cases referred to were not true eczema, but should be called dermatitis, such as those caused by the local irritation of minute hairs or raphides, while those which were produced by a poison affecting the blood generally might be considered to be true eczema.

Dr. Crichton said that green Elder leaves were very powerful irritants, and in one case in which he had ordered an application of Elder flower ointment, the druggist, having no flowers of the Elder at the time, used the green leaves instead, but this produced very violent irritation. The common Buttercup is also very irritating if applied to the skin.

CAMELLIAS AS WALL PLANTS.

IT is a question if we sufficiently realise the true worth of the Camellia for covering walls in winter gardens, conservatories, and greenhouses generally. There is no flowering plant that can boast of such a combination of high qualities as the Camellia, producing, as it does when in the full enjoyment of suitable conditions, foliage of the most dense and lustrous description, and flowers unsurpassed for beauty of form and colour. So long as gardening is practised in this country, so long will the Camellia hold a prominent place in the esteem of all plant lovers; and yet, in spite of all the love and admiration which has been for many years lavished upon this noble plant, it is a fact that it can scarcely be classed amongst really

popular subjects—that is to say, it is, as a rule, reserved to experienced gardeners to cultivate it; and a plant which is not universally grown by the owners or occupiers of small gardens can hardly be termed popular. That the Camellia is by no means a difficult plant to grow, those conversant with its peculiarities well know; and yet amongst small growers it bears the reputation of not being amenable to ordinary treatment. That this is a mistaken idea it would be an easy matter to prove, but into the pot culture of the Camellia I do not propose to enter. I may, however, remark that coddling and too heavy a compost are the stumbling-blocks which the amateur generally manages to encounter. A more natural mode of treatment, recognising the fact that the Camellia is really a hardy shrub, would work wonders, and would often be all that is required to ensure the right treatment being given. It may be safely asserted that wherever a greenhouse exists the Camellia may be grown to perfection, and that without unduly taxing the skill and resources of the grower. Far better would it be if the unsightly stages, which so often form a feature in cool plant houses, were done away with and the whole of the back wall covered with Camellias, which would, if properly treated, form a dense green curtain at all times beautiful, and which, from autumn until late in spring, would furnish an abundance of lovely flowers. Can there be anything more beautiful than a Camellia in full and lusty vigour—fresh, free, and bright in the way of foliage, the pearly white and bright pink flowers peeping out here and there in admirable contrast to the deep hue of the leaves? Nothing in the way of a floral display can be more beautiful than this, and it may be truthfully said that no pains would be too great to secure it.

WALL CULTURE.

There is no plant better adapted for covering a wall under glass than the Camellia, simply because it is one of the best of evergreens, and may easily be kept well and thickly clothed with verdure quite to the soil. Unlike the majority of those climbing subjects employed to cover walls, it does not exhibit such an almost unconquerable tendency to run away and expend its vigour upon the terminal shoots, to the complete impoverishment of the lower portion of the plant, thus denuding the base of the wall of foliage. On the contrary, by careful training in the early stages of growth, every part of the wall will be covered with a thick screen of foliage, fresh and delightful to the eye. The great point is to secure good young plants in 6-inch pots, seeing that they carry a head of foliage quite in proportion to the size of the pot, as in that case it may reasonably be supposed that they will be furnished with good roots. Such young plants are, as a rule, much better than older specimens for our purpose, as these latter are frequently somewhat devoid of young twiggy growth and leaves just where such is most required, and unless a good foundation is laid by thoroughly furnishing the base of the wall with free-growing wood, the result will really not be all that could be wished for. And now with respect to

SOIL,

about which many and diverse opinions exist, for loam, peat, leaf-mould, and mixtures in various proportions have been recommended by growers who should know something of the requirements of the Camellia. Let me, however, inform the inexperienced in this matter that very fine plants have been grown in pure loam, and equally good ones have been obtained when peat alone formed the rooting medium; at the same time I should warn the would-be Camellia grower that a loam fit for this plant to grow in in a pure, unmixed state is not easily procurable, and I have witnessed such disastrous effects arise from the use of loam of bad quality that I would urge the inexperienced to exercise great caution in this matter, the best and safest way being not to use it in an unmixed state. We will, therefore, take for our border good fibrous peat and loam in equal proportions, and, in order to ensure its remaining for all time in a free, sweet, open state, we will add thereto a goodly portion of coarse silver sand, throwing in as an additional precaution against stagnation a good sprinkling of

charcoal in pieces about the size of a Walnut. Here we have a compost at once light and nourishing. The size of the border will, of course, have to be regulated by the amount of space at the disposal of the grower, as well as the extent of wall to be covered. For a lofty structure the border cannot well be too wide, but for a small or medium-sized greenhouse anything from 2 feet to 3 feet in width and 2 feet in depth will suffice. The ordinary means for ensuring perfect drainage must be taken, which, for the benefit of those not well conversant with this kind of work, I may state to consist of placing some 4 inches of brick rubble at the bottom of the border, and covering the same with old turves, thus preventing the finer particles of soil from entering into and choking the drainage. The plants may be set out in March, taking care that the balls of soil are in a moist condition, and ramming the compost well around them. It is perhaps as well to allow an unrestricted development the first year of growth, commencing the training process the following autumn. J.

A GENERAL CALENDAR.

SEPTEMBER WEATHER.

THE delightful weather we have been favoured with during the past few weeks has given quite a new aspect to the garden and made it most enjoyable. Many of the sub-tropical plants that looked stunted and almost withered up earlier in the season are a wealth of beauty, and are more generally admired now than they have been all the season.

Begonias.—These are now at their best, and should we have no frost to mar them they will be a source of interest for some time to come. Immediately after the first frost these should be carefully lifted with the fork, leaving the growth intact, and placed in boxes or laid on the border of a cool Peach house or vinery. Left until the corms leave the stems, these may then be stored away, in dry soil or sand, in any dry frost-proof place for the winter.

Hardy Cyrtipediums.—Those who wish to be successful in the cultivation of these hardy Lady's Slippers should lose no time in getting them planted in their permanent quarters. In their native habitats most of the hardy Orchids are found close to damp Moss, Grass, or Sedge, often in bogs or other sub-aquatic situations. I have found by experience that these may also be grown successfully in almost any border where they can be shaded from the blazing noonday sun. Remove the ordinary soil to the depth of 1 foot, fill in with peat, loam, and leaf-soil. Add to this some fine broken crocks, a little coarse sand, and plant firmly; should the soil be dry at the time of planting give a good watering. It is a mistake to think that hardy *Cyrtipediums* can only be grown in damp places. In their growing season they must have copious supplies of water, otherwise they will do with ordinary treatment. *C. parviflorum* and *C. spectabile* I have found best for this kind of treatment.

Geranium Cuttings.—Now is a good time to put these in. The cool temperature of the past few weeks has taken the softness out of the younger growths. They will now be easier to manipulate, better adapted to root quickly, and likely in every way to be more successful than the succulent growth of a month or so earlier. If pots or boxes are used for the purpose of striking them in these should be stood out in the open air for a few days, giving them a good watering, and as soon as the sun has well dried them they should be placed in a frame, taking the lights off on dry warm days.

Strawberries.—Where it was not possible to get these plants in earlier, owing to the long drought, no time should be lost now. Very little fruit must be expected next summer, but the plants will be getting established and a good crop may be looked for another year.

Raspberries.—Cut away the old stems from which the fruit has been gathered and thin out the young growths, so that the best of the young canes

* Dr. Morris, C.M.G., in *Proc. Linn. Soc.*, November 5, 1896.

† *Proc. Linn. Soc.*, January 21, 1897.

may stand quite clear of their neighbours. On no account should these be overcrowded.

Cauliflowers.—These ought to be plentiful now, and if severe frost keeps off may be kept in supply until Christmas, or nearly so. Directly the hearts appear three or four leaves should be broken down so as to cover them. This will exclude several degrees of frost and help to keep them dry. On the approach of anything like severe frost it is an excellent plan to take up all the more forward plants, with good balls of soil, and lay them in closely in a pit or frame, where they will "turn in" almost as well as if left in the ground.

Endive and Lettuce.—Plant out the last batch of Endive, also more Lettuce. Should the weather prove mild this will be found most useful. A good batch of the Paris Market Lettuce planted out now in a cool house or pit will give some delicious and useful hearts about Christmas or a little later, according to the weather. T. B. FIELD.

THE KITCHEN GARDEN.

ONIONS NOT THINNED.

NOWADAYS there is such a demand for huge Onions, and for the purposes of exhibition they are an absolute necessity to win prizes, that one is apt to forget the kitchen requirements. To obtain the fullest crop of serviceable bulbs I am not sure that it is wise to thin the ordinary spring-sown Onions at all. Certainly those who do to get a uniform crop of the largest bulbs under ordinary treatment often have difficulty in producing quite small Onions for pickling. Often a small plot is set apart of some small growing variety for this purpose. Calling recently on Mr. Allan at Gunton, I noticed he had not thinned his Onion plot at all. In one cluster I counted as many as seventeen bulbs, some 3 inches in diameter. For general use here was a grand crop. E. M.

SAVOY SUTTON'S PERFECTION.

WHERE a Savoy of good quality and of medium size is required I would strongly recommend the above variety, as it appears to possess all these attributes. So highly does Mr. Cook value this variety that he grows at Sandringham huge breadths of it, and speaks well of it in every way. E. M.

ASPARAGUS.

IN trying to produce the finest Asparagus no doubt many persons grow it too thickly. Asparagus, like all other plants, must have space to develop its growth to the fullest extent. At Gunton Park Mr. Allan grows this vegetable extremely well; no doubt the soil there—sandy loam—assists him considerably. He grows his plants in rows 3 feet apart, not in the stereotyped bed fashion, where the roots are annually mutilated by digging out the alleys to cover the beds. Seven years since he made a new plantation, deeply trenching the soil first and adding manure liberally. In the spring vigorous year old roots were put out at the distance named, and now each clump measures on the ground quite 18 inches across. Just fancy the quantity to be had from such clumps! When the season is over Mr. Allan does not neglect the plants, but with short Pea stakes he supports the "grass" in each clump, so that the wind may not injure the crowns by causing them to sway about. He does not tolerate crops of weeds among the plants either, but gives the Asparagus the full benefit of the soil. How much more pleasant it is to have a full crop of anything in the kitchen than half a crop. E. M.

TOMATO UP-TO-DATE.

I REPEATEDLY see this Tomato in gardens in many parts of England, and, without exception, where Tomatoes are a success out of doors this is the best of all. I think it was raised by Mr. Allan, Gunton Park Gardens, Norwich, and I am sure it is a boon to all who require heavy crops of medium-sized,

well-formed, richly-coloured fruit, and that is the correct description of this variety. The fruit sets freely without artificial aid, is not corrugated, and is perfectly smooth. Given reasonable treatment, viz., good plants when put out and a sunny spot, the growth kept thin and watered when required, a good crop is assured. E. M.

LONG RUNNER BEANS.

WHEN a very fine sample of a Scarlet Runner Bean, a selection from Ne Plus Ultra, was placed before the fruit and vegetable committee at the new hall recently it was remarked that the Beans were too large. But the sample shown was so presented as to display its full capacities rather than its ordinary table fitness. I recently saw the variety Tydmonton Exhibition growing at Highclere Castle Gardens, where it was carrying a wonderful crop; the Beans hung in free clusters, and could be gathered by handfuls in remarkable abundance. The usual practice is to gather them when from 6 inches to 7 inches long, being then very tender and fleshy. The samples placed before the committee ranged from 11 inches to 12 inches long, but still were very tender and brittle. The progress made in Runner Bean production during the past twenty years is difficult to estimate. Certainly a good row of a modern variety will give three times the crop in bulk given by the old Scarlet Runner. A. D.

CYANIDE AS AN INSECTICIDE.

THE notes which have recently appeared in the gardening publications have made the useful qualities of hydrocyanic acid gas, when employed as an insecticide, abundantly clear. So much good has been said of it that some people have been tempted to believe that the horticulturist has at last obtained a perfect insect killer; but, unfortunately, it is not so, for though "cyanide" kills a great number of parasites, it does not kill them all. It has, moreover, a very bad effect upon some plants, a list of which experience alone will enable us to form. Since the American publications furnish us with interesting hints concerning its employment in the cultivation of Violets, and since the accounts which have recently appeared of the trials made at the Museum of Natural History, show its efficacious action on many parasites without damage to most of the plants treated, the study of the question should be completed, and we think it is a fit occasion to invite all horticulturists who have had, or are about to have, recourse to this insecticide, to make public the results of their observations.

Having for the last two years frequently employed hydrocyanic acid gas for the disinfection of greenhouses of considerable size (about 600 cubic metres), and having also submitted plants of different species to its action, in order to study their power of resistance, we will here sum up the results obtained. We will not insist upon the operation itself as described in detail in the article of MM. Constantin, Gérôme and Labroy, except so far as the immersion of the doses of cyanide of potassium in sulphuric acid is concerned, and this operation may be simplified in the following manner: Each dose of cyanide is enclosed in a paper bag; the latter is closed and furnished with a string about fifty centimetres long, this permits rapid immersion without the risk of splashing the acid upon the hands. The mixture of water and sulphuric acid having been prepared in all the vessels, the operator takes all the bags in one hand, and starting from one end of the greenhouse he deposits one in each earthenware pan, goes out, and shuts the door. The work should be done quickly but without hurry. The attack of the sulphuric acid upon the paper takes a few seconds, and by the time the freeing of the "cyanide" begins, the operator is already beyond the reach of the gas, the diffusion of which is not instantaneous. There is really not the least danger in working in this manner, the only one which is practicable in many greenhouses

where the ventilators are not above the path. The operation is rapid, and requires to be done by one person only. The head gardener can do it himself, and thus avoid the great responsibility he would incur should a workman poison himself through any imprudent action.

We have used "cyanide" against a small number of parasites only, green-fly, thrips, and red spider, with doses of one, two, and three grammes of cyanide of potassium per cubic metre of air, the duration of the fumigation varying from twenty to forty minutes. The fly and the thrips were killed by the three doses in a few minutes. As for the red spiders they always passed through the operation unharmed, no matter what dose was used, or the duration of the fumigation. A few minutes of stupefaction was the result obtained in the most favourable cases. The immunity of this insect is also corroborated by American horticulturists, as is shown by what Mr. B. T. Galloway says in his work "Commercial Violet Culture," page 193.

The following plants bore without harm doses of from two to three grammes of cyanide of potassium per cubic metre for twenty, thirty, and forty minutes: *Richardia æthiopica*, *Poinsettia pulcherrima*, Tree Carnations, and *Hidalgia Wercklei*. All the other plants which we have had occasion to submit to the action of "cyanide" in the doses mentioned above, have suffered from it to the different degrees mentioned below: Tomatoes.—The young parts, and the inflorescence about to develop withered within a few hours. *Asparagus plumosus nanus*.—The young stems withered two or three days after the fumigation; the adult stems remained unharmed. *Asparagus Sprengeri*.—The same effect upon the young stems; the adult stems themselves were attacked on some plants, the cladodes whitened and fell. Sweet Peas.—The young parts withered in one or two days. Potatoes and *Medeola*.—The same effect. Kidney Beans grown in pots.—At first the plants appeared to have suffered very little, the points of the youngest leaves only were slightly scorched. On taking some of the plants out of the pots, it was found that all the roots near the sides had been killed.

The unfavourable results mentioned above were observed after fumigations made at nightfall, or in complete obscurity, the plants being always perfectly dry. Thus it often results that from plants of different species being grown in the places to be disinfected, hydrocyanic acid gas cannot be used. However, the services it renders, where the nature of the plants permits its use, are very valuable, and this is why it is so desirable that methodical experiments should be undertaken in different directions in order to determine precisely its nature and the extent of its effects upon plants and upon the enemies of plants.

A. RICHON, in *La Revue Horticole*.

GARDENING OF THE WEEK.

FLOWER GARDEN.

EREMURUS.

SLOWLY but surely these noble herbaceous perennials are gaining favour. A flower lover has only to see a group, or even a single plant, in flower at once to have an intense desire to possess some. With a little protection, such as that afforded by a layer of leaves or cocoa-fibre during the winter months, the Eremuri are quite hardy. The essentials for their well-being are shelter from all rough winds, but exposure to direct sunshine, so that the roots are well ripened, and a rich, well-drained soil. A mixture of sound fibrous loam, leaf-mould, decayed cow manure, a little charcoal, and plenty of grit or road scrapings form a suitable rooting medium. I would not advise the addition of peat unless it is of the first quality; inferior peat quickly becomes sour and unwholesome. Allow a few days for the soil to settle. Keep the crown raised slightly above the surface of the soil and plant carefully, for the claw-like roots are very

brittle, and for this reason it is not advisable to move established roots of *Eremurus*.

While unplanted the roots should be kept in damp moss or fine soil, as in common with most of their order, Liliaceae, they deteriorate quickly upon exposure to the air. Small and cheap roots are usually very disappointing, as they take several years to become sufficiently strong to flower.

The *Eremuri* have been frequently illustrated in the pages of *THE GARDEN* that their general appearance is so well known as to render any description unnecessary. Of the score or so of kinds known, probably

THE FOLLOWING ARE THE BEST:

Eremurus Bungei, from Persia and Turkestan, and which bears yellow flowers having deep orange stamens; *E. Olga*, with curved and slightly glaucous foliage. The flowers are tinted bluish or lilac, and the anthers are yellow; *E. himalaicus* produces stems fully 6 feet high, and the upper portion is crowded with creamy white flowers; *E. robustus* is even taller than the last; the flowers, which are of a pleasing pink colour, are somewhat more loosely disposed, and are set off by orange-red anthers; *E. robustus elwesianus* differs from the foregoing in being somewhat stouter in habit, and in having slightly larger flowers. Here it did not attain the height of *E. robustus*, nor did the flowers last quite so long; but it is a most desirable plant, and, in common with the species, emits a pleasing perfume. The flowering period varies with the locality, and may be given roughly as from the latter part of May to July. *E. Olga* and *himalaicus* are the earliest, and the rarer but older *E. Bungei* is the latest to flower.

CALCEOLARIA CUTTINGS.

These and cuttings of *Gazania splendens* should now be inserted. Choose the smaller shoots which have no flower-buds and cut with a sharp knife. Where a quantity are required, the usual method is to make up a bed in a cold pit or frame. The soil should be sandy and contain sufficient leaf-mould to encourage root action. Cuttings firmly inserted at about 2 inches apart and kept close and shaded usually root freely. *Calceolaria amplexicaulis* is a trifle slower than the other kinds. A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

ORCHIDS.

DECIDUOUS CALANTHES.

To obtain the finest flowers it is essential to have well-ripened bulbs. When they have been given good manure water or have been grown with manure in the compost the bulbs will take far more maturing than those grown without the aid of manure. To bring about this ripening the plants should be placed in a light position, allowing plenty of room so that the heavy foliage does not prevent the light reaching the bulbs; a brisk temperature should be maintained with a good circulation of air. I do not advocate withholding water to hasten ripening so long as the foliage maintains its freshness. If that is done the foliage will draw from the supply of nourishment stored up in the bulb for flower production and to start the next year's growth. When the leaves begin to decay naturally then gradually reduce the supply of water, continuing the reduction as the decay of the foliage advances. When all the foliage is gone no more water is necessary. Growers who have tried the method I suggested on April 9 of growing *Calanthes* without the aid of manure will, I feel sure, see a great difference now in the colour and hardness of the bulbs compared with those grown

with the aid of manure. It would form a very interesting subject for discussion when the plants are in flower.

THUNIAS.

Those struck from cuttings this year should be ripened as quickly as possible. It is not wise to subject them to the same amount of rest as the old plants receive; sufficient can be given by placing them in a light position in the intermediate house, and gradually begin to withhold water.

CYPRIPEDIUM INSIGNE AND VARIETIES.

As the flowers appear they should be lightly secured to a slight stake. If this is deferred till they are fully opened the flower-stems are often-times crooked, and the flowers cannot be shown to the best advantage. Well-rooted plants should be kept well supplied with water on all favourable days, and on warm nights air should still be freely given, so long as the night temperature does not fall at this season below 55° no harm, but much good, will result from free ventilation.

THE ODONTOGLOSSUM HOUSE.

Many plants are now ready for repotting, and this work should be proceeded with at once, as advised in calendar notes of April 9 and August 6. Some that have been potted at other times this

work is taken in hand. Young trees making excessive growth and not fruiting satisfactorily should be lifted. Older trees that are making too strong a growth and are too large to be moved should be root-pruned. Before commencing to root-prune or lift water well to have the soil fairly moist. In root-pruning open out a trench 3 feet or 4 feet from the stem and gradually remove the soil without injuring the roots, carefully dig out the soil from underneath, cut off any descending roots, and carefully remove gross ones. Return a fair proportion of the old soil when filling in unless it is sour, or, when old worn-out trees are being removed and young trees planted, only a little of the top soil should be returned. Freely syringe transplanted trees. The earliest varieties should be planted in the warmest position facing due south, and later varieties between that and due west. Good outside varieties of Peaches are Hale's Early, Condor, Waterloo, Bellegarde, Dymond, Violette Hative, Princess of Wales, and Walburton Admirable; of Nectarines, Early Rivers', Dryden, Lord Napier, Stanwick Elruge, Humboldt, and Newton are all good.

APRICOTS.

These require similar positions to Peaches and Nectarines, and the same treatment as regards root-pruning, &c. Now is a good time to prune

LÆLIO-CATTLEYA ELEGANS AT THE WOODLANDS, STREATHAM, THE RESIDENCE OF MR. R. H. MEASURES.

year and do not now require it would benefit by having fresh surface moss. Every attention must now be given to see that slugs do not get the new roots that are freely pushed out; they play the most important part in building up a good pseudo-bulb. Traps, such as a little bran placed on a piece of crock or cardboard, or a Lettuce leaf, are both good. These and the plants should be inspected nightly. It is of little avail to give every other attention to their culture and neglect that of keeping down slugs. W. P. BOUND.

Gatton Park Gardens, Reigate.

FRUIT GARDEN.

HARDY FRUIT.

As soon as the fruit has been gathered from Peach and Nectarine trees root-pruning and lifting will demand attention. Good fibrous loam, lime rubble, and burnt ash to the quantity required should be prepared, so that there shall be no delay when the

trees and to reduce the number of old spurs if these are too thick or too long, as the best fruits are produced nearest the wall and the wounds heal more quickly at this season. If, however, the trees are crowded, too much thinning should not be done in one season, but allowed to extend over the next two years. Apricots should never be allowed to suffer for want of water at the roots. Moor Park is still one of the best varieties, although at times the branches die off suddenly. Other good varieties are New Large Early Hemskirk, Shipley, and Breda.

APPLES AND PEARS.

October is the best month to transplant young trees from the reserve garden or to lift and cut off the strong roots of those growing too vigorously. Any old worn-out trees that are incapable of producing good fruit should not be allowed to remain. In making new stations for Apples, Pears, Plums, &c., the work should be taken in hand as soon as possible. The ground should be well trenched

2 feet deep and well drained. In planting single trees prepare new stations 6 feet square and 2 feet deep. Good loam is generally all that is required. Lime rubble and burnt ashes should, however, be added, according to the nature of the soil, to induce the trees to make fibrous roots and short-jointed fruitful wood. Select those varieties most suitable for the purpose required.

Impney Gardens, Droitwich. F. JORDAN.

KITCHEN GARDEN.

LATE POTATOES.

MOST varieties are now ready for lifting. They should be picked over and stored, as advised in a previous calendar, for early varieties. Choose a dry sunny day for the operation, and allow the tubers to lie on the ground for an hour or two before they are gathered. Pick out all diseased tubers even though fairly good. If the haulms show signs of disease they should be removed at once from the garden and burned. It is most advisable to obtain a change of seed occasionally, and this is a good time to purchase. Prices often rise higher in spring.

BEETROOT.

In cold parts of the country this ought now to be taken up, but in the south it may be left for a month yet. A slight frost is considered beneficial, but all roots should be lifted during this month. In lifting the roots loosen them first (so that the main root may not be broken) with a digging fork. Cut the foliage off 2 inches from above the root, and stack them in a dark, frost-proof shed or cellar. Sand is the best and cleanest thing to use in storing. Place it between the layers. All extra large roots should be discarded, the medium ones being best in colour and flavour generally.

ASPARAGUS.

As soon as the growths on the old plantations are well ripened they should be cut down to the ground and the beds given a thorough cleaning. A top-dressing of good soil and well-decayed manure may be given now. It is too early yet to put on any covering material, and unless severe frosts set in the beds may be left bare. In many gardens the covering of Asparagus during the winter is being discontinued. In cold, wet gardens a covering of clean straw during severe frost would be advantageous, but on warm, light soils no covering is required. If new beds, or beds of seedling plants, are still green they should not be cut down till they show signs of ripening.

Cauliflowers

are still plentiful. Autumn Giant is doing well this season. Frost may be expected any morning now, so the leaves should be broken down over all heads fit for use. To prolong the supply the plants may be lifted and wheeled into a cool shady spot where they can be protected from frost. Plants from seed sown early last month may now be pricked into frames, keeping them hardy. The lights should be removed every morning, and only placed on during frosty weather.

Hopetown House Gardens, THOMAS HAY.
South Queensferry, N.B.

SELECT BULBOUS PLANTS FOR GREENHOUSE OR BORDER.

OF material for choice there is abundance, and it is probably the endless variety and the never-ceasing influx of novelties that make selection difficult. Some amateurs, fortunately for themselves, possess a sufficient knowledge of the different kinds, and a selection of good bulbous plants is to them an easy matter. Others, with less experience, find a difficulty in making a choice. Early planting is necessary to ensure the best results. Equally desirable is it that early orders should be given so that a good choice of bulbs or roots may be made.

ROMAN HYACINTHS.—Not only is the so-called Roman Hyacinth a most desirable subject on account of its early flowering and adaptability to forcing, but its value is enhanced by reason of most of the stock from which the British supplies are drawn having been for years past cultivated in a warmer country than our own, and thereby flowering and maturing earlier. The largest bulbs do not invariably provide the best spikes of bloom, but those rather of a medium size that are firm, solid, and possessing weight for size. The bulb that yields to the pressure of the hand is not the one that will give the best results, no matter how well cultivated. The best bulbs are the cheapest in the end, for it costs no more to tend them, while the produce may be doubled or even trebled. Bulbs of first size invariably yield two good spikes, and some even more. Timely potting, due preparation, and a long season of mild forcing are important items. From such treatment good spikes may be obtained early in November. The Roman Hyacinth may be had in bloom earlier than this, but the results generally are unworthy of the amount of fuel expended. Potted in the early days of September, plunged in ashes in the open for six weeks, well-rooted plants may be introduced into warmth from mid-October onwards where the earliest flowers are required. If flowers are not desired before mid-December pot the bulbs just as early, giving them a longer period of preparation, and, finally, when introducing them into the forcing house, do so by easy stages.

As the bulbs are plunged in the open, so they should be covered with cocoa-fibre refuse quite 6 inches deep when in the forcing house. Not only does this conduce to a uniform temperature, but it materially assists in bringing out what is often lacking—a good length of stem. Finally, when the blossoms appear remove the plants from the plunging material, return to the pit, and gradually inure them to the light. A moist temperature with a bottom-heat of 75° to 85° will be found quite high enough. Three bulbs will suffice for a 5-inch pot and five bulbs for a 6-inch pot. Firm potting, with the apex of the bulbs just visible above the soil, is the method generally adopted. Pots of Roman Hyacinths specially required for Christmas decoration should be brought in the forcing pit at least four weeks earlier. At this period it is quite an easy matter to obtain perfect pot-grown plants, and if gradually hardened they make desirable ornaments for the home. I have dwelt at some length upon the cultural requirements of the Roman Hyacinth, because of its early flowering and general utility. At the same time the principal cultural directions given will apply to other bulbous plants forced under glass.

THE DUC VAN THOL TULIPS.—These may be had in several shades of colour—rose, scarlet, white, vermilion, and yellow. They are now grown in immense quantities, and may be had in bloom from November onwards by adopting precisely the same cultural methods described for the Roman Hyacinth. They are bright, effective, and among the cheapest of bulbs suited to early forcing. Great numbers are grown in shallow boxes in market nurseries, and when in the full bud are potted up for sale. Quantities are also disposed of as grown in the boxes, and exceedingly bright and pretty they are. These dwarf Tulips are particularly bright and pleasing for Christmas and the mid-winter season generally. Van Thol Tulips, however, are quickly displaced by the bolder types of Tulips that are so much better suited for cut bloom. Of these, generally known as

SINGLE EARLY TULIPS, I give the following selection: Queen Victoria, shapely white flower, first early and splendid for forcing. As La Reine, this kind is the chief early white in the market for many weeks. As a bedder it is also good, and in the open the flower is suffused with rose; L'Immaculee, fine white pointed buds; Yellow Prince, like La Reine, is excellent for early forcing or for bedding. Of richly coloured sorts suited to early work I recommend the vermilion Jules Janin, not yet generally known. It is a large flower, shapely, and rich in colour, forcing well. For a succession to the above there are King of the Yellows, Pottebakker, Canary Bird, and Goldfinch,

all beautiful yellow varieties well suited to planting in the garden or for forcing. For second early forcing Vermilion Brilliant is to be recommended for its colour. It is of excellent shape. To these may be added, for bedding or succession under glass, Joost Van Vondel, white; Kiezerkroon, red and yellow; Pottebakker, white; Proserpine, rosy purple, very distinct; Thomas Moore, orange; Rosamundi (Hayckman), Queen of Whites, fine long-stemmed kind, handsome; Duchess de Parma, red, margined gold, a grand flower; Crimson King, Belle Alliance, scarlet; and Bacchus, deep red.

SINGLE HYACINTHS.—The following is a selection:—*White*: Albertine alba superbissima, *Grande Vedette, Queen of England, *Baronesse Van Thuyll, *Mina, L'Innocence, Marie Stuart, and *Mme. Van der Hoop. *Blue*: Electra, Czar Peter, *Grand Lilas, Baron Van Thuyll, Lord Derby, *Queen of the Blues, and King of the Blues. *Yellow*: Ida, King of Yellows, and L'or de l'Australie. *Red, rose, or crimson*: Etna, Incomparable, Roi des Belges, Gertrude, Prince of Wales, Prince Albert Victor, Lady Derby, Sarah Bernhardt, Rosea maxima, and Norma. Those marked with an asterisk are best for early forcing. All are well suited for pots or for bedding.

DOUBLE HYACINTHS.—I have given prominence to the single varieties as being the more useful, but I give a select list of doubles also. *White*: La Tour d'Auvergne, forces splendidly; La Grandesse and Princess Alexandra, very pure. *Blush white*: Edison, Isabella, and Princess Metternich. *Dark blue*: Charles Dickens, Garrick, and Van Speyk. *Rose shades*: Prince of Orange, Leo, and Lord Wellington.

SNOWDROPS.—Those of your readers who are interested in the flowering of the earliest bulbous plants, and who possess but small means for forcing the Tulip, Hyacinth, or Daffodil, should be the first to grow the many charming sorts of Snowdrops, for very few hardy flowers possess so much beauty and elegance, and none are better suited for pot culture in the greenhouse from which frost is excluded. A few pots or bowls filled with Snowdrops or Crocuses, or both, not only are delightful in the home, but they are equally valuable for transferring to a window-box at a date when so little is to be had in bloom. Snowdrops have not yet been grown in pots as much as they deserve. No cheaper and certainly no more dainty a flower could be had in the long dreary days of winter than the Snowdrop. A flower-pot 5 inches across will accommodate a dozen or more of the tiny bulbs, and if grown in the cool greenhouse for a few weeks a good flowering is ensured. The following are good ones: Galanthus cilicicus, flowering in November and December; G. Elwesii, of which selected flowering roots are very cheap; desirable where large numbers are required. G. E. cassaba, G. E. ochrospeilus, G. plicatus, and G. Ikariae, very large flower and arching leaves. There are also the single and double forms of the common Snowdrop (Galanthus nivalis), the type still perhaps the most elegant of its race. Any of these may be grown in pots, and all are of value and beauty in their day in the outdoor garden.

NARCISSI AND DAFFODILS.—These are of the greatest value for pots or the garden, and in another note I may refer to them alone. For the present I would like to mention briefly some that too frequently escape notice, but which nevertheless are well suited to the cool greenhouse quite early in the year. I mean the rich yellow Narcissus Bulbocodium; N. monophyllus, white; the very distinct yellow-flowered N. cyclamineus, N. minor, N. minimus, the smallest of all trumpet kinds, and simply exquisite when well grown in pots. Then we have N. triandrus (Angel's Tears), also very charming when pot grown under glass, which lasts in beauty a long time. If not required for earlier work, and I do not advise forcing for these, the above mentioned dwarf sorts if grown in the cold house or the coolest greenhouse that simply was safe from frost, would flower in company with such pretty hardy free flowering Cyclamens as C. Coum, C. C. album, C. ibericum, &c. All are very beautiful in pans and very dainty. These are of quite easy culture and very hardy.

Of quite a unique type of beauty are the many species of

BULBOUS IRISES, of which we may take *I. persica*, *I. Heldreichii*, *I. Histrio*, *I. histrioides*, *I. bakeriana*, together with the fragrant *I. reticulata*, and others. These are but a few of the great wealth of beauty to be found among the early Irises, and if only one of these could be grown I would recommend *I. reticulata*, of the richest violet-blue, and a delightful fragrance. It is an ideal pot plant. Two other groups of indispensable and fragrant flowers remain to be mentioned. These are Freesias and Lily of the Valley. In each instance special treatment is required to bring the flowers to perfection, and to this I may briefly refer in a subsequent note. E. H. JENKINS.

SOCIETIES.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE floral committee of this society held its first meeting of the season at Essex Hall, Strand, W.C., on the 19th ult., Mr. D. B. Crane in the chair. After the minutes of the last meeting had been read and confirmed, the election of chairman of committee for the present year was proceeded with. Mr. D. B. Crane was the only candidate nominated for the position, and he was unanimously re-elected. Four Japanese novelties were submitted for adjudication, a first-class certificate being awarded to

Leigh Park Rival.—This is a large and attractive exhibition bloom of good substance, florets long and broad, reflexing, curling and incurving at the ends. The colour is one of its chief attractions, this being a pleasing canary yellow, with a primrose reverse. From Mr. C. Penford, The Gardens, Leigh Park, Havant, Hants. The committee wished to see again

George Hutchinson.—A large and full relaxed Japanese flower, having long florets of medium width; colour deep rich crimson, with bright golden reverse, and with a golden centre. This is a flower of considerable promise, and from a later bud selection will be much admired.

SCOTTISH HORTICULTURAL ASSOCIATION.

ON Saturday, the 24th ult., a number of the members of this association visited the Redbraes nurseries of Messrs. James Grieve and Sons, Broughton Road, Edinburgh. The principal object of the visit was to see the large and choice collection of early-flowering Chrysanthemums, which were found in full bloom and in splendid condition. Their adaptability to cultivation in the atmosphere of a town was well seen, the collection at Redbraes being entirely cultivated in the open, and in a portion of the nurseries exposed to a good deal of smoke. Such, however, are the effects of good cultivation that the plants were in excellent condition and the flowers very fine. Among those of more recent introduction the following were observed: *Cactus*, fiery terra-cotta; *Carrie*, deep golden-yellow; *Charlie*, white, with cream centre, and a good habit; *Champ de Neige*, dwarf, snowy white, and a very fine flower; *Mrs. Vera Shaw*, creamy white, with blush tips; *Maggie*, deep yellow, with dwarf habit; *Polly*, an excellent variety with very deep orange flowers; *Rosie*, rich terra-cotta, and fine for cutting; *The Champion*, deep golden-yellow, and very fine; the fine *Goacher's Crimson*; and *Jason*, good yellow. The rich bronzy sport from Mme. C. Perier was noticeably good; and *The Sparkler*, crimson-scarlet, slightly incurved; *Satisfaction*, ivory white; *Mythett Pink*; and *Harmony*, rich apricot, shaded carmine-rose, were among the others of recent introduction. Such good older varieties as *Mythett White*, *White Mrs. Pitcher*, the dwarf golden-yellow *Pompon Pilgrim*, *Crimson Marie Masse*, and all the best of the other older varieties were in excellent condition and full of bloom. Among later-flowering varieties grown in very large quantities were *Soleil d'Octobre* and its bronze sport *La Triomphante* and its bronze and yellow sports, *White Quintus*, *Niveus*, *Nivette*, *Framfield Pink*, and others. The fine collections of choice Dahlias, *Pentstemons*, *Antirrhinums*, and French *Marigolds* also attracted much interest and were much admired, and many of the visitors took special notice of the *Violas* and *Pansies*, although the long-continued dry weather had told upon them. The large breadths of *Carnations* were just over, but had been unusually fine. Many other interesting flowers and plants were seen, and the pleasure of the members was greatly enhanced by having as their guide Mr. James Grieve, one of their most popular members. Messrs. Grieve received the hearty thanks of the members for their kindness and courtesy.

DUNDEE HORTICULTURAL ASSOCIATION.

THIS thriving association held its annual meeting in the Technical Institute, Dundee, on the evening of Friday, the 16th ult. There was a good attendance, presided over by Mr. R. Cairns. Mr. James Bethel, Westwood Gardens, Newport, the secretary, submitted the twenty-fourth annual report, which was very satisfactory, the session having been one of marked progress and continued horticultural usefulness. The report stated that there were ninety members on the roll, and that the average attendance at the monthly meetings was about fifty, a very satisfactory number considering the distance some members were from the place of meeting. Mention was also made of the high-class character of the exhibits, the number of first-class certificates awarded being seven. The annual accounts were also submitted, and were considered satisfactory, there having been an income for the year of £16 15s. 5d., while the balance in hand at the close of the year amounted to £4 2s. 5d. The retiring office-

bearers were heartily thanked for their services, and the appointments for the ensuing year made. Much interest was taken in the exhibits before the meeting, these comprising a group of *Carnations* sent by Mr. David Halley, and a good collection of *Potatoes* from Mr. William Nicoll. The former included a number of new varieties, and the cultural skill shown was very creditable to Mr. Halley, who, it may be mentioned, is an amateur. Mr. Nicoll's *Potatoes* were well grown, and especially interesting at a time when the *Potato* is receiving so much attention.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.

SEPTEMBER 6.—Present: Dr. Cooke (in the chair), Mr. Douglas, Dr. Rendle, Mr. Holmes, and the Rev. W. Wilks.

Pink Mould on Charred Wood.—Dr. Cooke reported that the pink mould on burnt wood, sent by Mr. Saunders, was common on all kinds of vegetable matter, dead or decaying, and had recently been claimed as a parasite on Apples (*Journal of the Royal Horticultural Society*, XXVIII., page 233). The conidia are profuse, colourless, elliptical, and uniseptate when mature. It is called *Cephalothecium roseum*.

Orchid Leaves.—Dr. Cooke reported that the light-coloured spots on *Cypripedium* leaf forwarded by Mr. Douglas were deficient in chlorophyll and semi-translucent, but contained no trace of fungi. The dark-coloured spots appeared to be scars from wounds, but contained no trace of fungi.

Pleiotaxy of Carnations.—Miss Harrison, of Wington, sent several specimens.

Supposed Damage from Foxglove.—Lady Roscoe enquired whether some deleterious substance did not come from *Foxgloves* which harmed other plants. She was also suspicious of *Nicotiana glauca* having the same effect, as plants near either seemed to languish. It was considered that any harm could only be done by the shade of the large leaves, or by the roots devouring all the food in the soil.

Diseased Oak.—Lady Mary Herbert sent specimens of disease in roots of Oak. The specimens plainly showed the marks of injury, and the disease had evidently been caused by water entering through the injured parts and causing ordinary decay.

Chermes laricis.—Lady Herbert also sent specimens of Larch attacked by this pest, now only too common. Nothing could be done, save to use one of the soft soap and paraffin sprays.

Soil.—Mr. Dean, gardener to E. Powell King, Esq., Wainsford, sent specimens of soil which it was proposed to use for Peach trees. It showed brown, thread-like marks, following the decay of some previously-existing roots. It was considered unsuitable for the purpose, as likely to engender fungus.

Nut-mite.—Adolph Reikmann, Esq., Nottingham, complained that, having been compelled to destroy his Black Currants on account of the bud-mite, the insect (or one very like it), seemed now to be attacking his Filbert nuts.

TWO TOWN DAHLIA SHOWS.

ONE of these was that of the North London Dahlia Society, the flowers which competed having been mainly grown within the borough of Hornsey or in adjacent localities. It was held in the large hall of the Alexandra Palace, Muswell Hill, a hall which would be invaluable for such purposes were it within easy reach of Charing Cross. The *Cactus* type of Dahlia was most largely shown, and some good blooms were staged; there were a few show Dahlias, also *Pompon* and single varieties, but it is clear that the *Cactus* varieties are in the ascendant. The common fault with the show flowers and also some of the *Pompons* was that they were cut when a little too much advanced in bloom, with the result that the centres had become defective. The society is young, but it should be said there is room for improvement both in the culture of the flowers and in the methods of setting them up. The space set apart for the flowers had a boundary line of very handsome exhibits of *Cactus*, *Pompon*, and single Dahlias from Messrs. J. Cheal and Sons, Crawley; hardy flowers from Mr. Amos Perry, Winchmore Hill; Dahlias, &c., from Messrs. W. Cutbush and Son, Highgate; Dahlias from Mr. J. T. West, Brentwood; and from Messrs. T. S. Ware, Limited, Feltham. Mr. Heming, the superintendent of the park, set up a large circular group in the centre of the hall, and an imposing bank of plants fronting the orchestra. A special gold medal was awarded to Mr. Heming.

The second town show was at Longton, Staffs., in the very heart of the Staffordshire Potteries. A favourite flower with very many of the working men is the Dahlia, and in order to afford them an opportunity of exhibiting in public the flowers they produce the Longton Dahlia, &c. Society was formed, and the first exhibition of the society was held in the Town Hall on the 12th ult. In addition to Dahlias there were prizes for other plants, for fruit and vegetables, also for the produce of working men's gardens. Mr. Peter Blair of Trentham, who judged the vegetables, was emphatic in praise of their high quality and the great care exercised in their cultivation. It is sometimes said—often as the result of a too hasty deduction—that the show type of Dahlia is going out of cultivation. It is quite certain that this is not so at Longton, and also in many other manufacturing localities. In the Longton Town Hall one could see a very large preponderance of large, finely moulded blooms of the show type, and I was as much surprised at their high quality as at their numbers. Unfortunately, the day being wet and the atmosphere heavy, with light admitted on one side only of the hall, the task of judging was a somewhat difficult one, as many of the stands had to be carried to the light. I awarded as many as thirteen prizes in one class for six blooms of show Dahlias, which gives some idea of the extent of the competition. The symmetry and evenness of the blooms were remarkable. Some excellent blooms of *Cactus* varieties, shown on boards, were also staged, and some pretty *Pompons*; evidently the single varieties are but little valued. Vases of Dahlias made a pretty feature, and there were some well-grown plants of

Pompon and single Dahlias in pots. If only adequate support be forthcoming, there is no reason why the Longton Dahlia Society should not become an important one in the Midlands. It was interesting to watch the exhibitors scanning the work of the judges. They are evidently not only well acquainted with the properties of the Dahlia, but also with the characteristics which constitute quality in vegetables. R. DEAN.

Obituary.—We regret to learn of the death of Mr. W. E. Boyce, secretary to the Highgate Horticultural Society and the Highgate and District Chrysanthemum Society.

Great autumn show of British

fruit.—It is owing to the erection of the Royal Horticultural Society's new hall that the great annual show of British-grown autumn fruit can, for the first time this year, be held in London. The first of this series of annual fruit shows was held at the Crystal Palace in 1894, and was repeated there each year up to 1903, when it was held in the society's garden at Chiswick, and this year we anticipate that an exceptionally large and fine collection of fruit will be brought together in view of the heavy crops all over the country. It should be specially noted that nothing but fruit can be shown at this meeting. The society's fruit committee will sit, but there will be no meeting of the floral and Orchid committees. The schedule of the show invites displays of fruit grown entirely out of doors and also from the orchard house, alike from amateurs, nurserymen, and market growers. In the gardeners' and amateurs' division classes are provided for collections of ripe dessert fruit, including Pines, Grapes, Melons, Peaches, Nectarines, and Plums; for collections of Grapes; and for a collection of hardy fruits generally. Numerous separate classes are given for fruits of every description, both for dessert and for cooking. Special classes for different counties, arranged in groups, for both Apples and Pears are offered for amateurs' and gardeners' competition. The public will be admitted to the show on the 4th inst. at 1 p.m. and at 10 a.m. on the 5th and 6th, and it will be kept open until 10 p.m. on the first two days, closing at 6 p.m. on the third day, and, like its predecessors, will doubtless prove the great progress which has been and is still being made in the cultivation of fruits in Great Britain. The charges for admission are 2s. 6d. on the opening day, and 1s. on the second and third days. Fellows of the society are admitted on showing their tickets.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening maybe, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 5, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Names of plants.—Subscriber.—Deadly Nightshade (*Atropa Belladonna*).—T. W. Harris.—Wild Guilder Rose (*Viburnum Opulus*).—J. Kift.—1, *Salvia patens*; 2, *Salicicella kraussiana* (often known as *S. denticulata*); 3, *Fuchsia splendens*; 4, *Erythrina Crista-galli*.—A. C. R.—An Artemisia, but without further information cannot decide the species.

Names of fruits.—Mrs. Phillips.—1, Reinette du Canada; 2, Stanford Pippin; 3, Court of Wick; 4, King of the Pippins; 5, Baumann's Red Winter Reinette.—G. H. Heath.—1, Lord Derby; 2, Fearn's Pippin; 3, Newton Wonder; 4, a local variety, not recognised; 5, Pear Maréchal de la Cour. Unfortunately the conifer was quite shrivelled, and it is difficult to name without a cone.—C. E. F.—5, Peasgood's Nonsuch; 7, Warner's King; 10, Beauty of Kent (all fine fruits).—K. J. Z.—1, Pear Forelle; 2, Williams' Bon Chrétien; 3, Beurre Giffard; 4, Seckle; 5, Plum Jefferson; 6, Plum Kirk's; 7, West Surrey.—1, Ribston Pippin; 2, Margil; 3, Dutch Mignonne; 4, Frogmore Prolific.—Tamworth.—1, Lady Sudeley; 2, Beauty of Bath; 3, probably a local variety; 4, Ecklinville Seedling.—H. W. Walters.—The Grape is Buckland Sweetwater, the Plum Oufin's Golden Gage. Apple No. 1 is Gloria Mundi; 2, Warner's King; 3, Lane's Prince Albert.—W. B. Hartland.—Both the large Apples are true Lady Sudeley, the difference

is probably due to the stocks being different. The small Apple is American Mother (true); it is also known as Mother Apple.

Trees in Bois de Boulogne (W. S. M.).—The tree you mean is *Paulownia imperialis*.

Geum Eweni (WILLIAM CUTTS).—We have noticed a similar malformation this season among many flowers, particularly the Compositae, and can only attribute it to the weather.

Laurel leaves diseased (HEDGE).—I could not find any of the maggot-like insects on the Laurel leaves you sent. The latter are attacked by one of the shot-hole fungi belonging to the genus *Cercospora*. Pick off the infested leaves and burn them, and spray the bushes with Bordeaux mixture if sufficient injury is being done to the hedge to make it worth while to do so.—G. S. S.

Wood for rustic work (WALTER WHITE).—The Oak and Birch occasionally produce fine gnarled knots upon their stems and branches, both of which are valuable, when properly selected, for constructing bridges over small streams, seats beneath trees, summer houses, and such-like structures which have a place in woodlands. Select suitable pieces of the branches with proper bends, and when dry store them away in a well-ventilated shed to season and be ready when wanted.

Begonia Count Zeppelin (H. COWLEY).—We regret that we are unable to give the origin of the budding variety of tuberous *Begonia* Count Zeppelin, but after a close examination of the plants we have come to the conclusion that it is simply a selection from the ordinary tuberous varieties whose ancestors, many generations since, were B. Pearcei, B. boliviensis, B. Veitchii, and B. Daviesi. This last, a particularly dwarf-growing species, has left its mark on many of the compact forms, and so doubt it played a part in the production of the variety about which you ask.

Slugs in garden (M. P. FORSTER).—Salt is most useful, but so much depends upon when it is applied and the kind of soil. We do not advise it in the way you think of using it in the autumn. Your ground being a strong loam, we fear the salt, unless used in large quantities, would do more harm than good. We would prefer using it, say, in February or March, when the earth will be in better condition, being warmer. We would much rather rely on fresh lime and soot applied freely in the autumn, and the ground turned up as roughly as possible. If the lime is placed on the surface, and when pulverised by exposure for a short time, dug in, you will find this effective. There are other aids. Gas-lime is splendid for the purpose. This procured in November or earlier, and a liberal surface dressing given (the lime having been broken as fine as possible), and then dug in, you will not only get rid of slugs, but other pests such as wireworm. As gas-lime used in a fresh state is very strong, it should be exposed on the surface for a few days, and there must be no large lumps. This material is very cheap, and will clear the soil for some years; it also prevents clubbing in Brassicas, and if used with care it is a splendid fertiliser. Early in the spring before cropping the surface-soil should be lightly forked over when dry.

Plants for conservatory wall (W. B.).—Suitable plants that are likely to fulfil your requirements for the position you name are by no means numerous, but of them we should give the first place to the Camellia, whose handsome leafage renders it highly ornamental at all seasons, and, in addition, the flowers are very handsome. If you object to the very formal flowers of the old-fashioned type there are several whose blooms are but semi-double. Whether one or more plants will be needed depends upon the size of your structure. One objection frequently urged against the Camellia for such a position is its slow rate of growth, a decided drawback if you want the wall covered quickly. In that case you might plant Abutilons, as they grow rapidly. If space exists for three they may consist of Boule de Neige (white), Golden Fleece (yellow), and Sanglant (red). *Habrothamnus* or *Cestrum* elegans, with ruby-red blossoms, and its near relative, *Habrothamnus aurantiacus*, in which they are yellow, will form a suitable pair for associating together. Lastly, the stronger growing Ivy-leaved Pelargoniums are good wall plants for a greenhouse or conservatory, but a north-west aspect is not a very promising position for them. Whatever subject you may choose, a well-drained border must be prepared for the plants, as they are more satisfactory so treated than under any other conditions.

Particulars of Peaches (R. K., St. Petersburg).—The following are full particulars of the Peaches you name. *Baron Dufour* or *Grosse Madeleine* de Metz (Simon-Louis, 1872).—In season from the middle to the end of August; large flowers, round glands; large deep reddish purple fruit; melting, sugary, and of excellent flavour; strong grower and good bearer. (Kaiser's description.) *Princess of Wales* (Rivers, 1860).—In season at the middle and end of September; large flowers, round glands; fruit large to very large, oval, creamy white, with a slight rosy red cheek; flesh white, melting, sugary, and of excellent flavour; good grower and cropper. *Pourprée hâtive* (of some). *Pourprée de Normandie*—*Grosse Mignonne*.—In season at the end of August and early September; large flowers, round glands; large pale yellow fruits, mottled with red, deep brownish red next the sun; rich, delicate, vinous, and highly flavoured; good grower and cropper. *Pourprée hâtive* or *grandes fleurs*—Early *Grosse Mignonne*.—In season the middle of August; large flowers and round glands; fruit medium size, thickly marked all over with bright crimson dots, pale red cheek; sweet, very juicy, and vinous; good grower and cropper. *Pourprée hâtive* or *cinquante* (of some)—*Belle Bausse*.—In season the middle of September; large flowers and very small, round glands; fruit medium to large, highly coloured with deep red almost all over; flesh melting, vinous, and excellent; strong growing and free bearing.

Planting Standard Roses (WARWICK).—Standards should not be planted so deeply in the soil as dwarfs, and should always be made firm and secured in some way until well established. There are few things so injurious to newly-planted Roses of this form as the whipping, twisting, and sagging they go through during the

winter unless firmly secured against the influences of wind and rain. As fast as new roots form they are wrenched off by the swaying about. It is easy to manure the surface soil after the Roses have partially permeated it with their roots; in fact, our experience points to many advantages of such treatment. In the first place, if the manure is added at the time of planting the soil is made too rich for the new roots, and a good deal of the fertilising properties of the manure is lost before the roots are able to assimilate it. Early planting, if properly carried out, is a great advantage, and we would recommend it, as then you secure a plant that becomes partially established before hard weather sets in.

Strawberry Keen's Seedling (W. S. KINGLAND).—You would be able to obtain plants of this variety from any of the fruit tree nurserymen who advertise in our columns. It is, as you say, an excellent variety, but has been somewhat lost sight of through the introduction of so many new sorts. Unfortunately, there are several varieties of Keen's, and those who get the inferior kinds soon condemn them, and rightly so. The true Keen's Seedling is one of the most reliable Strawberries for pot culture, and usually sets its fruits so freely that unless thinned early they will be small. For forcing it is all that can be desired. Fresh runners should be planted annually to obtain the best results.

Curious Fuchsia flower (M. M. LACCHLIN).—The Fuchsia flowers sent are both curious and interesting. They are, of course, malformed, and the plant will never be of commercial value. Fuchsias raised from seeds saved from varieties often exhibit some deformity in the flowers. In this particular case the sepals are perfect, but the petals, instead of being sessile, or almost so, on the calyx tube are cup-shaped, and borne on long red stalks similar to the filaments in the stamens. As you say that all the flowers are alike the plant will be worth keeping as a curiosity.

Moving ornamental trees (S. H. WILLS).—In lifting and moving large ornamental trees great care is necessary not to cut or otherwise injure the roots in course of the operation, and in order to guard against such a contingency it is well to use digging forks for this work in preference to spades, by which means the risk of damage is lessened to a considerable extent. In planting the trees, if the soil is poor and exhausted, some rich loam should be mixed with it. Spread the roots out well in all directions from the base of the stem, and take care to see that they do not cross or in any way overlap each other. Stake, tie, and fence the trees according to their requirements, and apply a good mulching to prevent a too sudden evaporation. If thought necessary finish by erecting a screen cage of branches around the tree to shelter and break the force of the wind until the roots are established. A very efficient shelter may be erected for this purpose by placing four upright posts in the ground at right angles and at a reasonable distance from the tree. Then by nailing on, say, three or four horizontal rails and warping in a few branches a useful screen can be formed at small cost, and on exposed situations will be found highly beneficial to the trees.

Some good Camellias (ROSE WALTERS).—You will find the following to be a selection of the best varieties:—*White*: Alba plena, flimbriata, mathotiana alba, and Duchesse De Berni. *Pinks and Reds*: Chaudrier elegans, Commaudore Berri, Coradino, Dade, Henri Favre, imbricata, Mme. de Strekaloff, Reine des Belges, Roi Leopold, rubens, Storyi, Valtavero, Wilderi, and Mme. A. Verschaffelt. *Crimsons*: C. H. Hovey, C. M. Hovey, mathotiana, and Mme. Lebois. *Striped*: Fanny Bollis and Jubilee. Grow them in sandy loam with plenty of leaf-mould, and give several applications of Standen's or Clay's Manure during the period of growth. Success in cultivation where the plants are kept in pots or tubs is to be obtained only by perfect root drainage, by exposure in the shade in the open during summer, by constant syringing and spraying, and by keeping the plants well supplied with water. Plants should not be put out before the end of June, and should be returned to the house by October 15. If plants in health do not flower it is because they are too vigorous or too young. The flower-buds are usually completely formed six weeks after the plant has started into fresh growth in the spring. The ordinary time of flowering is from December to the end of March. Flower-buds will fall if sufficient water is not given, and also if excessive variations of temperature are allowed in the plant house; 36° Fahr. are sufficient during frosty weather. Many degrees of frost will not kill the plant, but will cause the buds to drop.

The Egg Plant (WHARFEDALE).—We are not surprised that you did not recognise this plant, as it is comparatively rarely exhibited. The large quantities grown and consumed in France, and the high esteem in which they are held there and in other parts of the Continent for eating, may well suggest the enquiry whether it would not be worth while to grow them at home. Treatment that suits ridge Cucumbers, Marrows, and Tomatoes will suit Egg Plants. The plants, like other members of the Tomato family, are rather liable to the attacks of white fly and scale, but in the open air and with cool treatment under glass there is no difficulty in growing them. Few plants yield more fruit for their size than Egg Plants. The most ornamental with the closest resemblance to a pure white, rather small hen's egg is the original common white, but a large number of varieties may be seen in Paris and other Continental towns, and rich-looking purple fruits are sometimes 6 inches long. They are eaten when quite or nearly ripe—stewed, fried or baked, or used for flavouring and thickening soup. Another and original way of cooking the white is to open the fruit at one end, scoop out the pulp or flour-like substance, add bread-crumbs, minced meat, gravy, stock, or butter, and partly cook, then return to the shells, bake lightly so as not to destroy the form, and serve hot. We were years before we liked Tomatoes, and now we consume enormous quantities. It would be singular if we take to growing the Aubergine by the acre.

Growing Iris stylosa (H.).—There is no doubt whatever that this Iris requires a thorough baking during the summer, such as it obtains in its natural habitats, and a rather poor soil. We have seen this beautiful plant in

many gardens, but the flowers are more numerous when this treatment is given. At Ventnor it should succeed well. Plant out your bulbs at once, choosing a thoroughly well-drained spot, where they will be sheltered from cold winds. When in bloom put a highlight over the plants if snow or rain storms threaten. We wish its grassy leafage was less vigorous, as it hides the flowers. These cut when about half open are very pretty in a room, and their fragrance is delicate. They appear in winter, and are indeed welcome. Both blue and white kinds are equally hardy. We have seen luxuriant groups even in Midland gardens in warm, sheltered spots.

Spanish Irises (MONA).—Few plants require less culture than the Spanish Iris. It will succeed almost anywhere, but not in damp, low-lying, or shady places. Well-drained beds or borders, where the soil is light and warm, are the positions for these bulbs. They should be planted in quantity to get rich effects, and they happily fill a season when the flowers of spring have in a large measure departed, and those of summer scarcely opened. The flower coloring is very beautiful and varied. We saw this year a mass of Spanish Irises amongst bush fruits, and thought the effect very pretty, and these flowers helped to supply the house.

Planting Magnolias (ANXIOUS).—You may plant Magnolias in the early autumn or in spring, just as the leaves are unfolding and the roots becoming active. You must not plant in the winter. Magnolias are not very hardy plants, and if your climate is cold we would wait until spring. It is only in quite the southern counties of England that they may be grown as standards, and the soil must be good if the shrubs are to succeed. Good fibrous loam, to which peat has been liberally added, forms a good soil. Thoroughly incorporate the two materials. Magnolias dislike disturbance at the root, so that the position they are to occupy must be carefully chosen to prevent early transplanting elsewhere. It will pay thoroughly to prepare the ground, as the shrubs will make quick progress and show vigorous life. In the north of England the majority of Magnolias must be grown against a wall, and it is in this position that the evergreen Magnolia (M. grandiflora) succeeds. Against warm walls lately we have seen superb flowers. No matter what kind is planted, some shelter from keen easterly winds is essential. The early-flowering species, such as the Yulan or Lily Tree (Magnolia conspicua), needs the shelter of a belt of trees, especially to the east. The beautiful Water Lily-like flowers resist frost more when allowed to thaw before the morning sun strikes them than when fully exposed to its power. There are so many handsome kinds that it is not easy to give a list of the best without including the whole family. M. acuminata is the Cucumber Tree, and is very handsome on a lawn; its leaves are large, and the yellowish flowers fragrant. M. conspicua blooms quite early, before the leaves have expanded. It is one of the most beautiful of all, and there are varieties of it—soulangeana, flowering a little later and stained with purple, and nigra. M. grandiflora is best upon a wall. M. macrophylla has very fine leaves, and is worth growing on that account. M. stellata is a pretty early-flowering bush, its flowers white and starry; and there is also a bluish-coloured form, which, however, is rarer. M. parviflora and M. Watsoni are the newer kinds of promise. If you wish to add to the above list you may include M. tripetala, M. obovata, M. hypoleuca, M. Fraseri, M. glauca—a very handsome kind—and M. Campbelli.

TRADE NOTES.

TRANSFER OF SCOTTISH NURSERY BUSINESS.

The business of Messrs. Cardno and Darling, nursery and seedsmen, Aberdeen, has been acquired by the well-known firm of Messrs. William Smith and Son, nursery and seedsmen, Aberdeen. The amalgamated business will be carried on at the Exchange Seed Warehouses, Hadden Street, and at 26, Guild Street, Aberdeen. The transfer is interesting on account of its marking the reunion of a former combination after a lapse of about fifty years. In the early part of last century the firm was that of Messrs. Smith and Cardno. About the middle of the century the firm was dissolved, Mr. Smith, in association with his son, beginning business as William Smith and Son, and Mr. Cardno, in partnership with Mr. Thomas Darling, carrying on business as Cardno and Darling.

ANT. ROOZEN'S BULBS.

A COMPLETE collection of useful bulbs for the garden is enumerated in the autumn catalogue issued by Messrs. Ant. Roozen and Sons, Overveen, Haarlem (agents for Great Britain, Mertens and Co., St. Mary-at-Hill, E.C.). As well as all sorts of bulbs, the catalogue contains extensive lists of many hardy and tender plants, and will well bear perusal by all intending purchasers.

CATALOGUES RECEIVED.

Fruit Trees and Roses.—Messrs. George Bunyard and Co., Maidstone.

Currants and Picotees.—Mr. Hayward Mathias, Thames Ditton, Surrey.

Bulbs.—Messrs. Baker's, Wolverhampton; Amos Perry, Winchester Hill; James Cocker and Sons, Union Street, Aberdeen; Barr and Sons, King Street, Covent Garden; T. S. Ware, Limited, Feltham; Samson and Co., Kilmarnock.

Autumn Catalogue.—Messrs. H. Cannell and Sons, Swanley; Bruant, Poitiers, France; Peter Henderson and Co., New York; M. L. Spath, Rammshulsenweg, Berlin.

Hardy Plants.—Messrs. V. N. Gauntlett and Co., Redruth. **Conifers, Rhododendrons, &c.**—The Tottenham Nurseries, Limited, Dedensvaart.

Narcissus.—M. Ernest Benary, Erfurt.

Roses.—Messrs. William Paul and Son, Waltham Cross.

THE GARDEN

No. 1716.—Vol. LXVI.

[OCTOBER 8, 1904.]

A GREAT FRUIT SHOW.

THE ROYAL HORTICULTURAL SOCIETY'S
EXHIBITION.

EVERYONE would have been disappointed if the exhibits at the fruit show of the Royal Horticultural Society, which was held in the new hall, Vincent Square, on Tuesday, Wednesday, and Thursday last, had not been of much better quality than at last year's exhibition, for the summer of 1904 has been exceptionally favourable to the fruit grower, while that of 1903 was equally as unfavourable. It is satisfactory to know that rarely if ever has a finer display of fruit been seen at the annual show of the Royal Horticultural Society than this week, and the opinion was unanimous that the show of 1904 eclipsed those of several preceding years. Although many of the fruits were remarkably large, yet on the whole the colouring of the fruits was a more striking feature than their size. It was noticeable in the specimens sent from all parts of the country, the fruits from the Midlands, from the West, and from the North were hardly less richly coloured than those from the Southern Counties.

Competition in most of the classes was very keen, and the judges had a difficult work to perform in making their awards, for there was little to choose between several of the exhibits before them. Without in any way belittling the importance of the splendid collections of hardy fruit shown by nurserymen and others, we may say that a great deal of interest deservedly centred in the displays of orchard house fruits shown by Messrs. Bunyard and Co. and Messrs. Rivers and Son. The Apple trees in pots of Gascoyne's Scarlet Seedling, the fruits in baskets of the same variety, and the Marguerite Marillat Pears from Messrs. Bunyard, and the pot trees of Plum Transparent Gage, the fruits of Cox's Orange Pippin, Peasgood's Nonsuch, and Ribston Pippin Apples from Messrs. Rivers were alone worth a visit to the show. The trees of Apple Gascoyne's Scarlet Seedling and Plum Transparent Gage were models of what fruit trees in pots should be, and proved conclusively the value of this method of growing fruits when rightly carried out. Of fruits grown under glass Grapes were excellent, and so were Peaches and Nectarines.

One cannot visit such a display of home-grown produce, brought from England, Ireland, Scotland, and Wales, without meditating upon

the possibilities of the United Kingdom as a fruit-growing country. But it is an old, old story about the apathy of the farmer, and the methods of the fruit grower; pages have been written pointing out to both where they fail when brought into competition with alert growers in other parts of the world, and perhaps, at last, the truth of what has so long been urged is beginning to be realised. Be that as it may, there is no doubt that such a splendid display of British-grown fruit as was exhibited through the agency of the Royal Horticultural Society this week must bring home to the minds of all thinking people that we are not surpassed as a fruit-growing country so far as the quality of our produce is concerned. It is lamentable that the attendance of the general public was so poor. How strange that with such a splendid exhibition of home-grown hardy fruit on view in the heart of London, Covent Garden should be crowded with foreign importations of Apples, all commanding a ready sale!

At the luncheon given to the judges and others on Tuesday afternoon, Sir Trevor Lawrence referred to the good quality of the exhibits, and eulogised the skill of the fruit growers. Sir Daniel Morris, Imperial Commissioner for Agriculture in the West Indies, and formerly treasurer of the society, was present, and expressed the pleasure it gave him to be at the first fruit show in the new hall.

GOOD ORCHARD APPLES.

In these days of dwarf stocks, bush trees, and quick returns perhaps there is a tendency to overlook the value of the permanent orchard formed of standard trees on grass, which for generations has been an institution closely associated with British homesteads. It is to be hoped, however, that this is really not the case, for after all has been said in favour of growing Apples and Pears on dwarfing stocks with the object of securing quick returns, it must be remembered that an orchard is a permanent institution, and, when once established, it will, with reasonable care, continue to give a return for an indefinite period. There is no lack of evidence in support of this contention, for look where you will old orchards and old trees may be seen still in a state of bearing, though the men who planted them have long since passed away. We know that many of the old trees are of varieties which will not pass muster in these days, but for this no blame can be attached to the planters, who had to make the best of the meagre facilities they had when little heed was paid to varieties, fruit nurseries were comparatively few, and the

common method of propagating Apples was to raise the trees from seeds.

Still some of the old planters were aware of the advantage of growing good varieties, and the owners of many a giant Blenheim Orange tree to-day have to thank their forbears for their wisdom in planting the above variety, veteran specimens of which still continue to give good returns. I can look back thirty years and remember an orchard in a Midland shire containing several Blenheim Oranges and a few other good varieties, which are now in general cultivation. At the time I speak of the trees were considered to be old, and they certainly had a venerable appearance. They were planted in the first place by a man who was considered to be a local crank on Apples, and his neighbours laughed at him because he was not content to grow the local varieties of the district; but he knew what he was doing, and if he did not make much out of the orchard in his lifetime he always had a good Apple for his own consumption, and thirty years ago the then occupier of the orchard was envied by his neighbours for the price he always made for his Blenheims. The years which have intervened have not, of course, improved the appearance of the trees, which are now old and gnarled, but they still continue to bear fruit which would not pass through the ring provided to limit the size of fruits exhibited in the dessert class at the annual show of the Royal Horticultural Society.

But in these days we do not want to be contented entirely with the relics of a previous generation, or what should we have to leave for our successors? We need, on the other hand, to continue planting and establishing orchards on the best and most modern principles, making the most of the facilities at hand. Somehow a fruit orchard seems to be a natural adjunct to a country homestead. It a mansion or a farmhouse, and as years roll on and one watches young trees develop into sturdy specimens a tender sentiment seems to attach itself to each individual tree. This sentiment clings, and when one hears of a man scorning the idea of cutting down an old veteran, purely on account of the associations surrounding it, one can understand it, for, after all, the feeling is natural.

As the season for planting is approaching would-be establishers of orchards should consider the conditions under which they are working, particularly in regard to varieties. Good trees of the best sorts can now be obtained at such a trifling cost that no one would think of planting a poor variety. It is not sufficient for the purpose of orchard planting to make a selection from specimens seen at a show or exposed in a fruiterer's window, as the man who plants an orchard is doing something for posterity as well as for himself, and should therefore confine himself to the varieties suited to the purpose he has in view. The other day I heard a man bemoaning the fate which induced him to plant a number

of trees of Stirling Castle in his orchard some years ago on the advice of a friend, who assured him that it was a good Apple. Of course, it is a good Apple—everyone knows that—but not for an orchard standard, and the trees in question were fruit-laden and stunted, and can never make fine specimens. The result is that they will have to come out, other varieties must take their place, and the time which has intervened is practically lost. Lane's Prince Albert is another good Apple which is usually disappointing as an orchard standard, as it does not make a good head, though it answers well for grafting upon an established tree which has been headed back. These peculiarities of varieties are matters which should be carefully considered before selecting trees for making a permanent orchard, because through having the right thing in the right place at the outset waste of time and personal disappointment may be avoided.

There is naturally a difference in the conditions under which standard trees are grown in an orchard and bushes in a garden, and consequently vigour of constitution should be considered when making selections of varieties for the former style of culture. I have mentioned one Apple that can be depended on, namely, Blenheim Orange, and though it may be a long time coming into bearing, when it does arrive at that stage it will continue fruitful for a very long period. Bramley's Seedling is another Apple which has come rapidly to the front of recent years for orchard planting, and as a late keeping culinary variety it has no superior. Newton Wonder, said to be a cross between Blenheim Orange and Wellington, is another of the modern varieties which have made reputations for orchard work, and it is certainly a fine Apple. To mention a few others which may be relied on, we have Warner's King, Golden Noble, Beauty of Kent, Tyler's Kernel, Bismarck, Wellington, and Warner's King, while Worcester Pearmain, Devonshire Quarrenden, Cox's Orange Pippin, and other dessert Apples may be accorded places in orchards where soil and situation are fairly favourable.

Another point worth considering is that of distributing the varieties so as to make the most of the space and at the same time avoid overcrowding. Comparatively few people have the courage to plant trees 10 yards apart, but they give them much less space and excuse themselves on the grounds that alternate specimens will be cut out before they overcrowd each other. Sometimes the thinning is done, but more often it is not, as courage is certainly wanted to cut out a tree when it has only just arrived at a state of good bearing, and the result is that overcrowding is a standing evil. The proper course is to give plenty of room at the outset and allow for the filling up, but the habits of the trees should be studied. Varieties of spreading growth, like Bramley's Seedling, should not be planted together, as they are sure to grow into each other, but if such sorts as the above are planted alternately with varieties of upright habit there is no such danger, as the tendency of one is to grow upwards and the other outwards. Finally, let it be remembered that if a thing is worth doing at all it is worth doing well, and not even the most trivial should be scamped. Select for the orchard a suitable site, have the land drained if it holds stagnant moisture, take out wide holes and break up the soil well before planting, spread out the roots evenly and cover them with not more than 3 inches of the best soil, stake firmly, do not allow the grass to grow over the roots for the first few years. Above all things protect the stems so that there is no fear of damage by

horned stock, though a better plan is not to allow anything bigger than a sheep to graze in a young orchard. If these points are considered, good trees are planted, and due attention is given, Nature will not fail in her part, and the man who establishes a young orchard may live long enough to reap a good reward himself and pass something on to his heirs.

G. H. H.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

- October 12.—Royal Botanic Society's Show.
 October 12.—United Horticultural Benefit and Provident Society's Annual Dinner, Mr. W. A. Bilney in the chair, 6.30 p.m., Holborn Restaurant.
 October 18.—Royal Horticultural Society, Meeting of Committees, 12 noon.
 October 25.—Croydon Chrysanthemum Society's Show (two days).
 October 27.—Exmouth Chrysanthemum Show.
 November 1.—Bournemouth Chrysanthemum Show (two days); Brighton Chrysanthemum Show (two days); Royal Horticultural Society.
 November 2.—National Chrysanthemum Society's Show at Crystal Palace (three days); Southampton Royal Horticultural Society's Show (two days); Highgate Chrysanthemum Show (three days); Lowestoft Chrysanthemum Show (two days); Portsmouth Chrysanthemum Show (three days).
 November 3.—Weybridge Chrysanthemum Show; Colchester Chrysanthemum Show; Forest Gate Chrysanthemum Show (three days).
 November 4.—Windsor and Eton Chrysanthemum Show; Buttersea, Clapham, and Wandsworth Chrysanthemum Show (two days); Hineckley Chrysanthemum Show (two days).
 November 5.—Bitley and District Chrysanthemum Show; Loughborough Chrysanthemum Show; Penarth Chrysanthemum Show; North Lonsdale Chrysanthemum Show.
 November 8.—Ipswich and East of England Horticultural Society's Show at Ipswich (two days); Dalwich Chrysanthemum Show (two days); Sevenoaks Chrysanthemum Show (two days); Southend Chrysanthemum Show (two days); Stoke Newington Chrysanthemum Show (two days).
 November 16.—Liverpool Horticultural Association Chrysanthemum and Fruit Show (two days).

Hardy flower combinations.—It often happens that the best effects in the flower garden result from the association of familiar and easily grown plants, and it is equally true that the most beautiful flowers are not properly appreciated if they are injudiciously placed. As an instance of the former I may mention a very happy planting together of *Aster Amellus* *bessarabicus*, probably the finest and best coloured of this section of the Michaelmas Daisy and *Aster Linoxyris* (Goldlocks). The blue-purple of the first named and the yellow of the latter produced a pretty picture, and made quite a feature in the border in which they formed an item. There was a group of each planted side by side; the blue and yellow did not mingle indiscriminately. Another happy association of blue and yellow worth mentioning is obtained at this time of year by planting *Crocus speciosus* and *Sternbergia lutea* major. In Mr. Leopold de Rothschild's garden at Gunnersbury House these two bulbs are planted in grass beneath *Aranea excelsa* and make a delightful display. Another flower combination for September may be had by planting Tiger Lilies among white Japanese Anemones; the scarlet flowers and the red-brown stems of *Lobelia Queen Victoria* are also very effective among the pure white, gold-centred flowers of the Anemone.—Y. Z.

Some good autumn plants.—*Senecio Clivorum* and *Silphium laciniatum* are very effective when planted by the waterside. In the Gunnersbury House Gardens, Mr. Hudson has boldly grouped these plants, and at the present time they are a striking feature on the lake margin. As seen from the opposite side of the water their bold

foliage and rich yellow flower-heads add colour and dignity to the garden landscape. Both belong to the natural order Composite, which is so largely represented by plants in flower during late summer and early autumn. *Silphium laciniatum* is commonly called the Compass Plant, because in its native habitat—the prairies of North America—the leaves are said to present their faces north and south. Other good plants now flowering well at Gunnersbury are *Salvia splendens* *nana*, which makes a blaze of scarlet on a roof, and *Tropaeolum Fireball*. The *Tropaeolum* is planted in boxes placed on the edge of the lower part of the house, and the growths hang down for several feet, draping the sides of the building and making a curtain of red and green. I have never seen a *Tropaeolum* used more effectively. *Helenium macrocephalum grandiflorum* is an excellent plant for the back of a large herbaceous border, and *Kochia scoparia* for the front. The latter plant is rarely seen in gardens, but it is well worth growing. In summer the pretty foliage is a light and very pleasing green, while at this time of year it turns bronzy red. Groups of it near the front of the mixed border add variety and interest as well as a certain beauty. At Gunnersbury, Mr. Hudson has planted autumn-flowering Lilies very extensively. The beds of *L. speciosum* *Melpomene*, *L. s. Kratzeri*, and *L. s. novum album* are very fine; so, too, are those of *L. tigrinum* *Fortunei*. Is this variety synonymous with *L. t. giganteum*? I can see no difference; it is certainly taller than *L. t. splendens*. What a pretty flower *L. s. novum album* is. The petals are a clear white, and the anthers bright yellow. In *L. s. Kratzeri* the anthers are orange-yellow, and, to my mind, the flower of *novum album* is the prettier of the two, although *Kratzeri* is a more satisfactory plant to grow.—Y. Z.

Mr. James Whitton, Superintendent of Glasgow Parks.—Mr. James Whitton is the subject of a well-drawn sketch which has just appeared in one of a series being published by the *Glasgow Evening Times* under the title of "Prominent Profiles." The writer of the notice says: "Mr. Whitton has had much to do—the restoration of the Green, Kelvingrove Park, and the Botanic Gardens after they had been upheaved by the Central Railway operations, and the laying out of the Springburn, Rachill, Bellahouston, Tollcross, and Richmond Parks, and other open spaces which have been added to the recreation grounds of the citizens in recent years, while he has just completed the restoring of the site of the 1901 International Exhibition in Kelvingrove Park to the condition in which it was before that great undertaking." Reference is also made to the bowling-grounds, ponds, and golf courses laid out by Mr. Whitton, and his work generally receives kindly notice.

***Metrosideros floribunda*.**—What a showy plant this is when seen in good condition, and a first-rate climber for the south front of an ordinary greenhouse. At Westwick Hall, near Norwich, I lately saw several fine plants thickly studded with the bottle brush-like flowers. The rich crimson-magenta blossoms are distinctly attractive and last a long time.—E. M.

***Aster Finchley White*.**—This is quite the best white-flowered *Aster* I have yet seen. It grows but 2 feet 6 inches high, and produces huge pure white flowers measuring 2 inches or more in diameter. The florets are slightly cup-shaped, with a bright yellow disc. It is of desirable growth, and the flowers are pure white and massive in appearance.—E. M.

***Aster Perry's Favourite*.**—When placed before the floral committee of the Royal Horticultural Society this *Aster* was described as a seedling from *A. Amellus*, and as such it received an award of merit. It deserved this, as I consider it is a distinct break in colour in that section. I think it would more properly be described as a form of *A. Amellus* *bessarabicus*, which it much more resembles. The growth is taller and not so compact as in the type *Amellus*, which is quite distinct from *bessarabicus*. With me the latter will grow 3 feet high, and so will *Perry's Favourite*, but not so *Amellus*, which is just half that height.—E. MOLYNEUX.

Fuchsia Bright's Delight.—There are in cultivation Fuchsias having pink corollas, but I know of nothing so distinctly novel in this way as the variety named above. It was exhibited at a recent exhibition at Reading, where it was awarded a certificate of merit on account of its novelty of character. The tube and sepals are white, the corolla soft pink—a real pink; the habit of growth is compact, and it is very free blooming. It was raised by Mr. C. Bright, a gardener at Reading, who grows and exhibits very fine specimens of Fuchsias. It promises to make an excellent market variety, and of its value for exhibition purposes there can be no doubt.—R. D.

Single Cactus Dahlias.—Though there are some charming varieties among the group, it can scarcely be said of them that they have hit the popular fancy; and yet to see them growing one readily understands their value for border decoration, for they are of fairly dwarf and compact growth, and remarkably free of bloom. Messrs. Dobbie and Co. of Rothesay, who make a speciality of this type, catalogue nearly forty varieties, a few of which they staged at the last meeting of the Royal Horticultural Society, but they had evidently suffered during the long journey from Rothesay. A good half-dozen will be found in Amy Robsart, bright scarlet, the florets twisted and curled; Feneila, crimson, deep orange, and pink; Ivanhoe, bright rose, with a crimson band round the yellow centre—one of the very best; Meg Merrilees, clear yellow with twisted florets; Novar, crimson-purple, shading to magenta; and Sir Walter, rosy pink, with deep orange disc, the florets much twisted.—R. D.

A new Pear.—This season our best early autumn Pear is undoubtedly the new Michaelmas Nelis, which is not very well known. It is not a large fruit, but quite large enough for dessert. For good quality it is difficult to beat; indeed, as a late September and early October Pear I do not know one better. It may be termed an early autumn Doyenné du Comice. My notes only refer to trees grown as cordons, but my experience is that a good cordon invariably makes a good bush or pyramid tree. Very small trees fruit freely, so that it promises well, and it grows freely. I have referred to its quality, and this season it is very good indeed. The fruits may be termed under medium size, and are very sweet and juicy. They are in season at Michaelmas. We have no lack of early Pears, but none too many of first-rate quality, so that this new one will be welcome. I think it will prove a free grower in any form.—G. WYTHES.

Apple Worcester Pearmain in 1904.—In some seasons different fruits vary greatly in quality. Much depends upon the season, the soil, and the time of gathering. This year Worcester Pearmain is greatly superior in size, colour, and quality to those of the last two seasons, and there is no question whatever as to its crop, as this variety rarely fails even in adverse seasons. I think in such seasons as this it is difficult to beat. Growers of this Apple, which was sent out thirty years ago by Messrs. Smith of Worcester, do not require any information as to its market value. To the private grower it is most valuable, but it varies greatly even in the same garden. Our best fruits are produced from small standard trees. I much prefer this form to bush trees. Those on the Paradise stock do not fruit so freely with us, but, as previously stated, this may be quite the reverse elsewhere.—G. WYTHES, *Middlesex*.

North British Railway station gardens.—The awards of the annual premiums offered by the directors of the North British Railway Company for the best-kept stations on their lines have just been issued. The total sum offered is £400, divided into 200 prizes in four classes, the premiums being as follow: First class (20), £4 each; second (40), £3 each; third (60), £2 each; fourth (80), £1 each. Arrangements are made by which those who have been in the higher classes cannot take a premium in the same class for more than a certain number of times in succession. The following are the twenty stations in the first class, with the names of the stationmasters: Aberlady, Mr. Yorkston; Ayton, Mr. Spence; Blackford Hill, Mr. Cunningham; Blairhill and

Gartsherrie, Mr. M'Kelvie; Burnmouth, Mr. Watt; Causewayhead, Mr. M'Lean; Chirnside, Mr. Christison; Craigenordan, Mr. Whyte; Dalmuir, Mr. Sheddon; Dirlton, Mr. Watson; Eskbank, Mr. Thomson; Glenfarg, Mr. Brown; Grants house, Mr. Thornburgh; Junction Road, Mr. Campbell; Kirkandrews, Mr. Gourlay; Kirkintilloch, Mr. Ferguson; Morningside Road, Mr. Cullen; Rothbury, Mr. Renton; St. Fort, Mr. Bathgate; Tyndrum, Mr. Robertson.

Statice sinensis.—With the exception of the well-known blue-flowered *S. sinuata* and the yellow *S. Bonduelli*, along with the other annual *Suworowi* and one or two perennials, including *S. tartarica*, the Sea Lavenders are not met with so often as they might be. The present species often goes under the name of *S. Fortunei*. It has been in cultivation for over half a century, and is well worth growing. Treated as an annual and raised early in the year in heat and planted out when large enough it will begin flowering in September. If sown the previous autumn it will come into flower earlier in the year. It is a light, graceful plant, growing about 2 feet or 3 feet high, with freely branching twiggy stems, ending in myriads of small yellow flowers. The everlasting character of these make them valuable for house decoration when cut and used for that purpose.—W. I.

Show of Colonial fruit, preserved fruits, and jams.—The winter show of the Royal Horticultural Society, which will be held in the society's new hall, Vincent Square, Westminster, on December 13 and 14, will be confined to Colonial-grown and to preserved fruits. Classes are arranged for all descriptions of Colonial fruits, and the preserved fruits include jams, as well as bottled and dried fruits, separate classes being arranged for home, Colonial, and foreign exhibits, the comparative value of which will thus be seen side by side. The December show will remain open on both days until 10 p.m., so as to give all classes of the public an opportunity of seeing specimens of the varied products of the British Empire. The Agents-General and Crown Agents are most kindly rendering every assistance, and we trust that both growers and exporters will do their best to send in exhibits worthy of our Colonies, and to show what can be produced for the home markets. No entrance fee or charge for space is made, and if desired the produce may be consigned direct to the society, and it will be stored in the cellars at Vincent Square and staged by the society in good time for the special private Press view on the evening of December 12, but the society cannot undertake to repack and return such exhibits. We further learn that a second show of Colonial fruit will be held in March or April, 1905, with a view to showing such fruits as cannot be shown in perfection in December. Copies of the schedule and entry forms may be obtained on application to the secretary of the Royal Horticultural Society at Vincent Square, Westminster.

Scutellaria Ventenatii.—Though introduced from Columbia just sixty years ago, this *Scutellaria* has only within the last few seasons had any special attention directed to its merits as a flowering plant for the warm greenhouse throughout the greater part of the year, but especially during the summer and early autumn months. It is, however, very useful, especially where a display of flowers has to be kept up at all seasons, for its cultural requirements are not at all exacting, and its bright coloured blossoms are always welcome. It is a soft growing, freely branched plant, in general appearance not unlike a *Salvia*, and if stopped when young it forms a neat little specimen about 18 inches high. The deep scarlet flowers, which are produced in erect terminal racemes about 6 inches long, are somewhat tubular in shape, and individually small, but borne in great profusion. Cuttings of the young growing shoots strike root very readily during spring and early summer. Of the other tender species the best is *S. mociniana*, a native of Mexico, from where it was introduced in 1868. This is more upright growing than the preceding, the tubular-shaped flowers $\frac{1}{2}$ inches long, in colour scarlet outside and yellow within, being borne in large terminal heads. This must

not be stopped too freely, as three sturdy shoots each with a fine head of blossoms are most effective.—H. P.

Lilium tigrinum jucundum at Kew. This form of the Tiger Lily has flowered well during the present season at Kew, and as seen there it certainly merits a place among the most select of outdoor Lilies. One marked feature in which it differs from all the other varieties of this species is in the absence of small bulbils in the axils of the leaves which are so numerous in the other forms. The stem, too, is more slender, and the leaves narrower and longer, while the flowers are of a bright orange-red with numerous small dark brown spots. It is fairly prolific in names, being known beside the above as *Lilium pseudo-tigrinum*, *L. Maximowiczii*, and *L. Leichtlini rubrum*; indeed, it may be sometimes seen referred to as a red *Leichtlini*, but it is certainly far more nearly related to *L. tigrinum*. At Kew there was a favourable opportunity to compare these two Lilies, as *L. Leichtlini* was flowering in close proximity to the bed of *jucundum*. Other varieties of the Tiger Lily worthy of note are *splendens* or *Leopoldi*, characterised by fine bright coloured flowers with larger spots than in the ordinary form, while the stems are dark coloured and quite smooth. A good example of a double flowered Lily is furnished by *L. tigrinum flore-pleno*, whose petals overlap in a regular manner, but for beauty it cannot to my mind at least compare with the single kinds. Last to mention and last to flower is the bold growing *Fortunei*, with pyramidal heads of rather light coloured flowers. The excessive wooliness of the stem and young leaves is a notable feature of this variety.—H. P.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

TWO NEW CARNATIONS.

Mr. W. A. Watts writes from Brounwylla, St. Asaph: "I am sending you a few blooms of two of my new Carnations, Mrs. Kearley (blush-coloured) and The Master (scarlet). They were each awarded a certificate of merit at Shrewsbury by the Shropshire Horticultural Society last month. The blooms I send are only small ones, but you will understand that they are from side stems; as it is late in the season there are many buds still to open."

[Two varieties of distinct colouring and unusually strong, non-bursting calyces.—Ed.]

SOME AUTUMN PINKS.

From Messrs. Ladhams, Limited, Shirley Nurseries, Southampton, we have received a gathering of Pinks, delightful so late in the year, and quite as fresh and bright as those of June. These perpetual-flowering varieties of the Pink, of which Messrs. Ladhams recently exhibited an excellent group, are most acceptable in the garden at this time of year.

BELLADONNA LILIES FROM GUERNSEY.

Messrs. Charles Smith and Son, Caledonia Nursery, Guernsey, have sent flowers of several varieties of *Amaryllis Belladonna*. Perhaps the finest of all is *purpurascens maxima*, of which we gave an illustration some months ago. The flower-stems of this were 18 inches long, and Messrs. Smith inform us that before sending them 15 inches

THE IRIS WALK IN THE EARL OF ONSLOW'S GARDEN AT CLANDON PARK.

were cut off, so that the full length of the stems was 33 inches. The flowers are deep rose coloured. Other varieties sent besides the typical form were blanda (rosy pink and white, sweetly scented) and rosea perfecta (rich deep rose, sweetly scented), altogether a delightful boxful of these autumn flowers.

EUCALYPTUS GLOBULUS IN FLOWER.

Mr. Cuckney sends from the gardens, Cobham Hall, Gravesend, shoots in flower of this well-known Eucalyptus. They were cut from a plant in a pot in an Elizabethan orangery, but it is the shoots that have been allowed to reach the open air that have flowered. This is the second year it has bloomed in this way.

GIANT BULBS OF GALANTHUS ELWESII.

From King Street, Covent Garden, Messrs. Barr and Sons send some very large bulbs of this Snowdrop, more like those of Tulips than Galanthus, with this note: "We are sending you here-with a sample of remarkably large specimen bulbs of Galanthus Elwesii, together with a sample of the ordinary size. The bulbs are imported from Asia Minor, and we send them just to show you the great size that this variety of Snowdrop is capable of attaining."

ZEPHYRANTHES ATAMASCO.

Mr. S. W. Fitzherbert writes: "I supplement Zephyranthes Andersoni, which I sent you a short time ago, with Zephyranthes Atamasco and Z. candida, the first named being the larger of the two."

GIANT HELIOTROPE.

"I am sending you a few heads of giant Heliotrope for your table." [Very handsome and of good colour.—Ed.] "I consider it one of the finest bedders that we have, and it deserves a place in every garden. It is of easy culture, and grows freely in a compost of loam, decayed leaves, and sand. I sow the seed in spring on a slight hotbed, where it germinates very freely. When large enough to handle I prick out or pot the seedlings, and plant in the open in early June. This Heliotrope grows about 2 feet high, and is of branching

habit. I have grown it for several years, and it is always much admired. I find it to be neither satisfactory in pots nor when grown from cuttings. —E. HAYWOOD, Bryn-y-pys Gardens, Ellesmere, Salop."

EARLY CHRYSANTHEMUMS FROM A CITY GARDEN.

Mr. E. B. Handley writes from Greenfield Crescent, Edgbaston, Birmingham: "I am sending you for your table a few early-flowering Chrysanthemums gathered from my small garden within a mile of the centre of the city. I have no doubt that the varieties will be easily recognised by you, but I have just ventured to label them. The Aster which I enclose is a self-sown seedling that I found."

[The Chrysanthemums included Carrie, lemon-yellow; Mrs. A. W. Willis and Bronze Bride, bronze; Polly, orange; and Goacher's Crimson. The Aster, evidently an Amellus variety, is of good colouring, deep rose-purple.—Ed.]

HYBRID TREE CARNATIONS.

Mr. Hayward Mathias, Thames Ditton, Surrey, writes: "I send you blooms of my new hybrid seedling Tree Carnations, which have resulted from cross-fertilising the best English varieties with the best of American introductions. Out of more than 600 seedlings I have selected about eighteen varieties worthy of further cultivation, some of which are among those I send you. The flowers are rather small, being chiefly side blooms, but some idea as to their form and colouring is obtained from them. I have been trying for several years to produce a distinct class of Tree Carnations, that is, varieties resembling the American in size with the English form of petal, with a more robust habit of growth. The American Carnations, without doubt, a very lovely strain. The flowers of most of the varieties introduced measure quite $3\frac{1}{2}$ inches to 4 inches across, while for decorative purposes I consider so far they are unequalled. Owing to the petals of most of them being serrated, they are not so popular as they deserve to be. The English notion of an ideal Carnations, whether it be a tree or border variety, is a perfectly smooth-edged petal. I quite agree with this being the chief point of an exhibition border variety, but in Tree Carnations grown for decorative purposes I consider a slightly serrated petal rather adds to than mars the beauty

of the flowers. However, you will note that I have been fairly successful in my endeavours."

[The flowers sent by Mr. Mathias bear out what he says about them. There is no doubt a good deal to be done in the direction in which Mr. Mathias is a pioneer. Some of the best of those sent by Mr. Mathias are Rubens, rich bright rose; Firefly, a bold and handsome salmon-red flower; Ajax, dark ruby-red, sweetly scented; Calliope, purple; Diadem, rich rose; Circe, white ground, flaked with dark crimson; Cherry Girl, salmon-red ground with scarlet flakes; Thunder Cloud, rose and slate blue; and Fairy, buff ground, flaked with bright red.—Ed.]

MAURANDIA BARCLAYANA OUT OF DOORS.

We have received the following interesting letter concerning the outdoor culture of this Maurandia, together with flowering sprays of this and Solanum jasminoides: "I saw in your issue of the 10th ult. a notice of Maurandia barclayana flowering in a sheltered position in a southern aspect and unprotected in winter. I venture, therefore, to enclose you some sprays I have just picked from south and east walls of my house here. They were sown three years ago and planted out, and have since been left to take care of themselves. They are now flowering in a tangled mass with Solanum jasminoides at a height of 12 feet or 14 feet. The Solanum I enclose, too, has gone right up to the roof, and is a wealth of blossom in both south and east aspects, and is never protected in winter.—LAURA WARWICK, Birchlands, Englefield Green, Surrey."

NOTABLE GARDENS.

GRIMS DYKE.

THIS, the seat of Mr. W. S. Gilbert, is situated in a secluded spot between Harrow Weald, Pinner, and Stanmore. The grounds are quite naturally laid out, and their beauty is much enhanced by the dyke and water-courses that exist, and from which the place takes its name. The largest sheet of water is surrounded by an irregular walk, which affords an interesting view of the plants that thrive on the banks. In the centre is a large island planted with Rhododendrons and Bambusa Metake. Many of the hardy Nymphaeas have made large patches and flower profusely. There are also clumps of Bulrushes, Spireas, &c. From this pond the water falls into others, parts of which are beautified in a similar manner. Although much of the work has been carried out recently by the present head gardener, Mr. Fulton, one would hardly take the grouping to be artificial, so cleverly has it been planned and carried out. Vistas open up many charming views of the surrounding country. On leaving the pleasure grounds grassy walks fringed with Bracken lead in all directions to the adjoining woodlands and form a delightful feature.

The glass houses are situated inside a partly walled kitchen garden. The stove contains some well-grown plants of Ixoras Duffii, Williamsii, coccinea superba, and Westii, all in full bloom, and some well-grown and finely-coloured Codiaeums were as good as could be wished for. Melons are largely grown; those ripe and approaching ripeness were excellent fruits. The Vines were bearing very fair crops, but the vineries are not ideal for first-class Grape culture. Good crops of Peaches and Nectarines were noticeable, both under glass and outside upon south walls. The Pear crop upon walls outside is very regular, especially good being Clapp's Favourite and Doyenné du Comice. The vegetable quarters are well managed, and excellent crops are seen throughout. In the orchard standard Apple trees were bearing abundantly, such varieties

as Lane's Prince Albert, Golden Noble, Tower of Glamis, Worcester Pearmain, and Bramley's Seedling being loaded with fruit. The flower garden, although not extensive, nevertheless is not without interest. The plants are bright and tastefully arranged, and harmonise well with their surroundings. Both Mr. and Mrs. Gilbert take great interest in their garden, and encouragement is given to Mr. Fulton to bring everything to a successful issue. C. J. E.

THE EARL OF ONSLOW'S GARDEN, CLANDON PARK, SURREY.

THE Earl of Onslow kindly sends several photographs of his interesting garden, from which we have selected two for reproduction, one of the beautiful walk of Irises, and the other of Water Lilies in the lake. The following notes were also sent: "The Iris walk is along the banks of a stream that runs through Clandon Park. After some years' work all the known forms of Iris have been obtained, so that there is a show from February until September, although this year the late-flowering ones were over at the end of August, in consequence of the hot weather. The path leads to the Lily bed, recently made in front of a Maori house, which was brought over by the Earl from New Zealand at the expiration of his term of Governorship."

KNIGHTON, KESTON, KENT.

In the neighbourhood of Keston, Kent, it is hard to realise that one is so short a distance from London, yet, as a matter of fact, this village is only fourteen miles away. Keston village is situated on the crest of a hill more than 400 feet above the sea level, and on the south side the view is varied and beautiful. Away to the south lie the well-wooded Surrey hills, and as far as the eye can reach the country is beautifully undulating. Nestling among the trees of what is known as Leafy Grove is Knighton, the residence of Mr. C. T. Boosey. Gardening at Knighton has been very difficult, partly on account of the shallow soil, but more particularly because of the somewhat precipitous slope of the garden. To overcome these difficulties a series of terraced gardens was formed. The ground had to be cleared and useless and unsightly timber cut down. In this way many of the finer specimens of the original wood were preserved; they have increased in vigour and shapeliness, adding attractiveness to the surroundings. Immediately below the terrace, running level with the house, an interesting alpine garden has been made on the slope leading to the next terrace. Flower-beds are also arranged along the upper terrace garden, in which a good strain of Verbena seedlings were very showy. Beds of Ivy-leaved Pelargonium Mme. Crousse and a pink zonal Pelargonium named Gertrude Pearson made a bright display. In the alpine garden the Androsaces, particularly *A. lanuginosa*, were doing well. The sweet-scented rosy pink *Daphne Cneorum* was flowering out of season, and the tufted growth of *Shortia galacifolia* and colouring leaves were specially good. *Acena microphylla*, Sedums, Phloxes, and other plants made this alpine garden well worth a visit. In the centre of the rock garden is a small pool in which some of the hardier Nymphaeas are growing satisfactorily, as well as the Cape Pond Flower (*Aponogeton distachyon*). On a lower terrace is the tennis court, the slopes of which are planted with British Ferns, and by the free use of rustic timber a natural effect has been obtained.

Recently borders for herbaceous perennials have been made, and others are in course of preparation. Further development of the pleasure grounds are to be carried out in the near future, so that each succeeding season the gardens will increase in size and beauty. Here and

there in the wood hardy Azaleas have been grouped, and in their season provide a welcome piece of colour. Reference has been made to the shallow depth of soil. In the kitchen garden much has been done to increase the depth of soil and to make it workable. A heavy and retentive loam on a chalky subsoil is not one that can be lightly taken in hand, yet notwithstanding these disadvantages the kitchen garden is full of well-grown plants. Fruit on a limited scale is cultivated. Flowers for indoor decorations were to be seen. Sweet Peas in clumps, and such as *Gaillardia grandiflora*, *Coreopsis grandiflora*, so useful for cut flowers, and *Chrysanthemums*, for cut flowers as well as for large blooms, were very good. Mr. Newman, the head gardener, has displayed much skill in the development and management of this garden. D. B. C.

THE FLOWER GARDEN.

THE HERBACEOUS BORDER.—II.

IN my last article I gave a somewhat sketchy description of a herbaceous border, dealing with its general effect; but as I propose treating very fully every detail of this form of gardening I think it will be better to change my programme a little, and say a few words on the preparation of the border. As I remarked in my last article, we have to deal with a variety of different plants, so we must prepare a habitation that shall meet all their requirements. We will suppose that an entirely new border has to be made, and whether this is to be on virgin ground or on soil that has already been cultivated matters little, for it should be entirely reconstructed. Suppose the border to be about 6 feet or 7 feet wide. We begin by removing the soil to a depth of 4 feet, and then we must make a good bed of broken bricks or rubble nearly 1 foot deep, and if possible cover this with a layer of ashes. Then we shall require good soil, composed of equal parts of soil, sand, and burnt garden refuse, 2 feet or 3 feet deep, well mixed with matured farmyard manure obtained from the best possible source. The danger of buying

manure from a farmer who starves his animals, and who does not thoroughly till his ground, is not sufficiently considered. But it is a source of much evil—poor soil and the introduction of wireworm—which once in your garden will work endless havoc. We cannot, as a rule, choose either our situation or our soil, but we can improve the latter gradually and surely by careful cultivation.

Most of the hardy flowers, and more particularly those of a sturdy growth, enjoy a good loam, rather stiff than otherwise, while for the smaller plants and bulbs a lighter soil is desirable. With the addition of sand and leaf-mould a stiff soil can be made suitable, and if, on the contrary, it be too light and dry crushed clay may be added with a larger proportion of manure; but be careful not to make the soil too rich where you intend to plant Daffodils, for they greatly resent gross feeding. Old stumps, stones, and roots of pernicious weeds, like the *Convolvulus arvensis* or Field Bindweed, should be carefully eliminated, a precaution that will save any amount of labour and worry in the future. When the preparation of the border is completed time should be given for the soil to settle down and to be warmed by the sun and sweetened by the breath of heaven. The birds, too, are of incalculable benefit in picking out the worms and grubs and generally scavenging the soil. When you are sure it is fit it can be gone over with a hay rake, and planting may begin. Autumn and early spring are the two seasons for these operations. I infinitely prefer the autumn, but it is advisable to leave the planting of the more delicate subjects until spring, so that they should not have the rigours of a winter to contend with before they settle down in their permanent home.

Supposing you have neither wall, hedge, nor paling behind your proposed border, but must have some sort of division from the rest of your garden, I should advise your planting a good selection of ornamental shrubs as a background, choosing those that bloom attractively, or have brightly-coloured foliage. To begin with there are the Lilacs, white and purple, of

THE NYMPHÆA POND IN THE EARL OF ONSLOW'S GARDEN.

which beautiful floriferous varieties may be had. Dr. Lindley, with fine reddish clusters, Dr. Masters, a pure lilac, while for the white Marie Lezraye can hardly be beaten. Between the shades of purple-lilac put the *Kerria japonica* or the *Berberis wallichiana*, which has quantities of clear yellow flowers, intensely sweet in the spring, followed by an abundance of purple berries. Then with the *Weigela rosea* and *alba*, Broom, white and yellow. *Syringa* and *Laurustinus*, the *Laburnums*, and a few of the Japanese Maples to give colour in the autumn, you will have a charming compact hedge, not too formal, with plenty of colour, as a background before the taller plants push up.

I saw lately a good effect produced by pillars of the various rambler Roses at the back of a herbaceous border. Aglaia, wreaths of pale gold; Dorothy Perkins, charming double pink flowerets; the Apple blossom-like Waltham Rambler; and Queen Alexandra, while the favourite Crimson Rambler eclipsed them all. But it is in spring and autumn we want to increase our colour strength. At midsummer we have a wealth of beautiful flowers, and a perpetual rambler has yet to be evolved. Now in front of the shrubs, but not too close—for remember how fast these coarse subjects grow—plant Phloxes, carefully selected from an excellent list given in *THE GARDEN* for September 3, arranging the colours judiciously and avoiding all those of a magenta tone. You must calculate the distance apart according to the length of your border, for you have a large variety of other plants to work in. Then suppose we take the Rudbeckias and Helianthus of good named sorts and the white Daisies—*Pyrethrum uliginosum*, and *Chrysanthemum maximum*, which is earlier. The former, though it is charming and most useful for cutting, must be used sparingly, for it increases at a fearful rate. Then mix in the Golden Rod, *Solidago canadensis*, and the later flowering *ultrissima*. Next come the Michaelmas Daisies, disposed among the foregoing plants. The Star Asters are now of such endless variety that the difficulty is in the choice, but avoid the old coarse foliaged kinds, as they flower badly. You must use all this material with care and judgment. Purple, yellow, and white alternating. Remember this is your autumn flower show, and that the Phlox will most probably be looking shabby before the Michaelmas Daisies are in full bloom. Purple, white, and gold will then predominate, and a very lovely colour combination it is, mixed with the green and white ribbon Grass and giant Maize. Do not forget to slip in a few hybrid Foxgloves, they will serve you in good stead in early summer, when your ornamental shrubs have done blossoming, and when once established will appear every year. Also plant a few good Hollyhocks to succeed them later, whose charming spikes of many colours will tower grandly above all other things.

Now we come to the second row. First in my choice are the Delphiniums, particularly the lighter shades. The scarlet and crimson Oriental Poppies work in well, keeping the two colours at some distance; Peonies, single and double, and the old-fashioned Columbines. I lay a stress on old-fashioned, for I do assure you that the best of them are infinitely more effective in a mixed border than the spurred Aquilegias. Their foliage is much richer and more compact, and though the flowers are not individually as delicate and graceful in tints, they are more telling in colour. Then come the beautiful Lupins, light blue, dark blue, purple, white, and yellow; the scarlet *Lychnis*, most useful and striking; *Potentillas* and *Geums*, somewhat unsatisfactory and straggling,

but still acceptable; *Monarda didyma*, perfumed and handsome, but a bit of a tramp; *Spireas*, pink and white; *Achilleas* and *Galegas*, several *Campanulas*, and *Erigeron speciosum*.

In the third row you shall have the hybrid *Aquilegias*, *Heuchera sanguinea*, the pretty metallic blue *Eryngium amethystinum*, Japanese *Anemones*, and other plants of like nature too numerous to mention. And here begin the bulbs, *Hyacinthus candicans*, *Montbretias*, Spanish Iris, and *Lilium longiflorum*, unless you have a Lily border separate. Then in the fourth row Sweet Williams (a self-coloured variety called Pink Beauty is very useful, for pure pink is a scarce colour), Iceland and alpine Poppies, Wallflowers of all shades, and Canterbury Bells in large clumps of distinct colours. Then as we get towards the front we will have *Dianthus* and border Carnations, *Polyanthus* and Tulips, Daffodil and Narcissus, Forget-me-nots, and hybrid Primroses, the Poppy and St. Bridgid *Anemones*, if they will do with you, and then next to the wide turf margin, which I hope you will have between your border and the gravel path, put low-growing things, *Aubrietia* (plenty of this), *Violas*, yellow *Alyssum*, and Rock Cress, and now, save for the annuals, your border is complete. I will treat of these last in the future. Probably some gardeners will criticise this scheme as formal, but you must remember that order is Heaven's first law, and that in a few weeks after the spring growth has commenced there will be no formality, and very little order. The rapidity of the growth of plants is extraordinary; science is beginning to calculate it by minutes. This being the case, it is most desirable to plant with regularity, and as much as possible with regard to height. But I deprecate the planting in large patches of one sort of plant of the same height. Once in the garden belonging to a beautiful place I hurried eagerly to see the herbaceous borders, which I had been told were wonderful. I looked and, bitterly disappointed, I turned away. I cannot remember what flowers composed the centre of the borders, but there were large bays up the entire front, filled alternately with dwarf *Antirrhinums*, *Zinnias*, Stocks, Asters, French Marigolds, and *Coreopsis*, about fifty plants in each. The gardener remarked that it was a very difficult piece of bedding, and, like Dr. Johnson, I almost exclaimed, "Would it had been impossible!" I also do not hold with placing a large plant in the foreground to break the monotony. There is no monotony if Nature is not outraged. French Poppies will spring up uninvited, and will flower so delightfully that you will forgive them for taking French leave. A provoking orange Marigold will fill a blank, and, so that it is not too close to a crimson flower, you will let it remain against your better judgment. When your herbaceous border has been established a couple of years you will pull up a great deal more than you will put in, and every cottage garden in the neighbourhood will confess to legitimate, or illegitimate, appropriation of your superfluous beauties. You have now collected every available plant to give you colour through April, May, June, July, August, September, and perhaps October. But do what you will—work as hard as you like, nip off dead blossoms, trim and prune, water and manure—I cannot promise you an absolute success, for the forces of Nature are against you as well as for you, and each succeeding summer there will be different mistakes and failures. I find myself apologising to my visitors as I march them along my borders for vacant spaces and

withered plants, and then I see that it is the whole effect that they are looking at, and that a mass of colour and sweetness should be the aim, if not the end, of the mixed border.

AUGUSTA DE LACY LACY.

SWEET LAVENDER.

IF there be one herb more than another that we may regard as thoroughly English, fragrant in itself and redolent of good housewifery, it is Lavender. Speaking without book, one might be apt to say that it was dear to Shakespeare's gardening heart, yet in his day it must still have been rare or no great favourite of his, for he makes but scant allusion to it once only—in "A Winter's Tale." Nevertheless, it was introduced into our gardens from Southern Europe as early as the sixteenth century, and, in common with many an imaginative writer, we have accustomed ourselves to-day in thought to wed the hoary grey of Lavender bushes with the terraces of stately Elizabethan mansions, and to associate them no less with many-gabled, roomy homesteads and old-fashioned gardens filled with hardy fruits and flowers. We picture to ourselves the capacious chest or "armory"—a pretty old word-relic of France which still lingers in Scotland—well stocked with household linen, mostly homespun, and laid away with Lavender pressed lovingly between the folds by gentle mother-hands, to wait the time when the children shall go forth from the parent roof to homes of their own. All this is now only an echo of the past, though the tender memory lingers with us still. It was but the other day that a misguided townsman was heard to say, "Ah! yes; your sheets in the country always smell of Lavender." What a sadly mistaken idea! No village inn nowadays can boast of its Lavender-scented bed linen. The broad Oak staircases and bright polished furniture, the cosy carven settles, and the rare old china beau-pots filled, as the seasons came round, with Snowdrops and Lilies of the Valley, with Damask Roses, or, daintier far, the white Rose of Provence—all these, and Lavender bushes amongst them, which used to be the pride of countless old-fashioned hostleries, where are they? Nothing is left of them but shadowy memories put away in the inmost recesses of our thoughts, and only brought out now and then with the same sense of half-pitying condescension with which we unfold the faded silks and satins of some long-forgotten ancestress.

But why this dejected train of thought? It may be told in a few words. There is a sweet Sussex village, well known to the writer, with comely, deep-roofed farmhouses, each with its quaintly steeped oast-house, with pretty weather-tiled thatched cottages, having more than garden space enough to satisfy all reasonable needs, and yet—would it be believed?—amongst a group of sixteen householders, living in this unspoiled country village—with ample garden room to every cottage—who were being entertained at a garden party a few weeks ago, not one possessed a Lavender bush. It was almost pathetic to listen to the exclamations of genuine delight with which some goodly rows of Lavender and Rosemary were hailed. "Lavender. Oh! what a beautiful lot. I haven't seen Lavender growing this many a day." "There's one bush, maybe down at Brownlow's," naming a distant farm. "A muslin bag of Lavender was given to me years ago; I have it in my basket yet, for it's sweet-scented still." "Please may we beg some slips," and so the chorus went on.

Of course, we know that there are Lavender grounds at Mitcham, Hitchin, and elsewhere. Nor do we now consider distilled Lavender one of the most refined of scents. But this does not touch the point that Lavender is no longer, as it used to be, a universal garden inmate. There is, besides, another significant fact which it would be well to bring before the minds of garden lovers—that the Lavender of commerce no longer produces seeds as it did of old, but has now to be propagated entirely by cuttings or divisions. One may try in vain to save seed of both the common and the white Lavender—it is all abortive: not one single grain is to be found. With the pretty earlier-flowering dwarf Lavender, a plant not half so much known or grown as it should be, seeds are both plentiful and easy to raise. It is supposed that over-production, by the speediest method of rooting cuttings, is the cause of this degeneracy, for it is a sure sign of wearing out. Lavender is a short-lived shrub at best, and not among the hardiest. So it might happen at no far distant time that we may read over against its name: "Formerly a favourite sweet-flowering shrub in English gardens. Now extinct."

Miss Jekyll in her charming and most helpful books has done more to bring back the old-world fragrance of Lavender and Rosemary to our gardens than any other modern writer. To her we owe the delightful suggestion of Lavender planted with the sweet old Monthly Rose. To her, too, is owing the bountiful supply which gave so much pleasure to the village matrons aforesaid, which will in its turn, it is hoped, repair the lack of our own country-side gardens. But surely it behoves us all, who love our gardens and desire that our less fortunate neighbours should have some measure of the same enjoyment, to follow her lead and to do our part, each in our own environment, in bringing back the cult of homely border flowers and the fashion of using the simple scents which a garden can produce. For, in truth, the delicate garden perfumes of Lavender and Verbena and dried Rose leaves are fast giving place to coarse chemical compounds, in high favour nowadays with country as well as townfolk, whose tastes only need a little training in better and more refined directions to enable them to realise that such strong incense leaves a trail behind it in the pure air of the country lanes almost as obnoxious to sensitive nerves as the petroleum vapours of the ubiquitous motor-car. K. L. D.

THE HAMMOCK UNDER THE OAKS.

SOME AUTUMN FLOWERS.

OCTOBER is a busy month for the amateur gardener who does a great deal of her own planning and planting. What we used to call the "Barren Hill," under the shade of some Oak and Ash trees, we are now trying to transform into a "Hill of Flowers." The little girl and I slip out there every morning, armed with trowels, a bag of bulbs, and an old tin saucepan. Old black Tom has made us a good many miniature ditches and holes in the hill-side with his pick-axe. Then he hauled us a load of rich compost from the barnyard, mixed with rotted leaves. The rest of the work we must do ourselves. It consists of filling up the little ditches by the aid of our trowels and the saucepan, and then planting the bulbs in the soft mould. On either

side of the little footpath that winds over the hill we have planted in this artless manner hundreds of Garibaldi, Mammoth Golden, Mme. Mina, Mont Blanc, and Baron von Brunow Crocuses. Another part of the hill is reserved for a planting of *Narcissus poeticus ornatus*. These *Narcissus* bulbs and many more are ordered, but have not yet arrived. The garden is still furnishing abundant bloom, but it is outrivalled by the glories of the marshland at the foot of the pasture fields. This marshy ground, through which runs a Mint-bordered stream, is brilliant in purple and gold of Asters, Ironweed, Golden Rod, many wild *Rudbeckias*, *Coreopsis*, wild Sun-flowers, and other Composite. In the wild garden here also the autumn flowers are unusually showy and luxuriant. The abundant rains of this phenomenal year have brought forward all vegetation, as the rainy season does in tropical climates.

A few plants tried for the first time here have been interesting and more or less successful. One of these is *Nicotiana sylvestris*, not altogether new in the flower market, but new to us at Rose Brake. This plant is listed by some of our seedsmen as an annual, but with us it has more of the character of a tender biennial. Seedlings planted last year and kept in the plant-room over winter bloom about midsummer in the open border. We have one at this time (which is the first week in October) still in full bloom. It has been in flower since August 1. This *Nicotiana* is very different in appearance from *Nicotiana affinis*, with its meagre foliage and stiff, nearly upright flowers. It is a noble and stately plant, and grows from 4 feet to 5 feet in height, with leaves soft as velvet to the touch, the lower ones lying on the ground and over 1 foot in length, about 6 inches in width, oval, but tapering to the base and clasping. The main stalk was topped early in August by a shower of blossoms delightfully fragrant, especially in the evening, longer than those of *N. affinis*, and pendulous around the stalk. The plant has many branches, all topped by these pendent blossoms, and it has tier after tier of the handsome light green leaves. As a single plant remains in flower for more than two months, and as it is a most conspicuous ornament of the flower garden during that period, this *Nicotiana* seems to be a valuable addition to the small list of species already in cultivation. In order to encourage the growth of the branches it is best to break off the main stalk as soon as the blossoms fade.

Some of the late *Phloxes* are still in full beauty. We find that those planted in the shade outlast those in full sun and do not dry up, as they have a tendency to do in hot and dry weather. A pretty picture in one of the borders is made by a group of *Caryopteris Mastacanthus*, which has greyish foliage and abundant heads of small lavender-blue flowers. In front of the *Caryopteris* are two large clumps of *Phloxes* 3 feet in height. One of these is *Adonis*, a late-flowering variety with large florets of bright China rose colour. The other is *Oberon*, a most charming sort, with flowers of rich deep crimson. I consider this one of the best and most brilliant of crimson *Phloxes*, especially valuable for its late-blooming habit. These two harmonise well, and, with the *Caryopteris*, furnish a gay bit of colour.

In what we call the Dutch garden, with its sunken beds and little brick-paved paths, there has been an unprecedented growth, owing to the remarkably wet season. The plants have burst all bounds, and riot across the narrow paths in wild abandon. It has taken constant

diligence to prevent the tall *Nasturtiums* on the fence from strangling the *Roses* in the borders below. It has been a good season for *Roses*. *Enchantress*, *Maman Cochet*, *Grüss an Teplitz*, *Caroline Testout*, *Mrs. John Laing*, *Golden Gate*, and *Adrienne Christophle* have all been fine. A young *Lamarque* planted last spring from a 4-inch pot has grown 6 feet and given us many flowers.

Nellie Curtis is a *Rose* of climbing habit with numerous clusters of loose double white blossoms. The original of this *Rose* blooms at Mount Vernon, George Washington's home on the Potomac, and was named after his step-daughter. It is a rapid-growing, hardy, and free-flowering climber, the small blossoms very fragrant, as almost all old *Roses* are.

In the centre of one of the square beds in the Dutch garden we have a large *Solanum azureum*, planted from a tiny pot in May. This bed is all in blue and white. Around the *Solanum* are some tall *Cosmos* plants, looking like miniature trees of hairy foliage. The *Solanum* has grown to the top of these plants which it o'er-canopies, and, in full bloom, with many clusters of sky blue blossoms, it is a pretty sight, suggesting a tropical forest in miniature with great *Lianas* creeping up to the summit of the trees. This *Solanum* is so pretty that we intend to take it up and pot it for winter decoration of the plant room.

DANSKE DANDRIDGE.

(To be continued.)

NOTES ON HARDY PLANTS.

ERYSIMUM PEROVSKIANUM.

IN the brightness of its orange tint there are few flowers that approach this *Erysimum*, which quite eclipses that of *Cheiranthus Marshalli*, and the statement in Nicholson's "Dictionary of Gardening," that it is "one of the showiest hardy annuals grown," is well merited by the plant. I remember some years ago, at the end of August, being struck by the sight of a rough slope in Abbotbury Castle Gardens entirely covered with this *Erysimum*. The effect of the mass of brilliant orange was gorgeous. Seed sown in September will flower in the early spring and April-sown seed in August. The plants will grow anywhere, on gravel paths or wall-tops, appearing as happy as *Wallflowers* under these conditions. In beds of rich soil the slugs often clear off the whole batch, as they are inordinately fond of the plants, leaving everything else for them, so that precautions must be taken to keep them away until the plants have formed hard stems. Considering its brightness and beauty this annual is surprisingly little grown. S. W. F.

NEPETA MUSSINI.

THOUGH not a particularly showy plant, this old perennial, which was introduced into this country from the Caucasus in 1804, is distinctly valuable, since it remains in bloom for many months. It commenced to flower early in June, and now (at the end of September) is still blossoming well. The flower-racemes are about 18 inches in length, and are thickly set with small lavender-blue blossoms, which render large plants, 3 feet or more across, breadths of soft colour. The plant is, of course, absolutely hardy, but is rarely met with in gardens, though it is well worthy of a position in the herbaceous border. The lavender flower-sprays arranged in a small vase are pretty for indoor decoration. S. W. F.

PHLOX PANTHEON.

THE number of *Phloxes* is so great that it would be a matter of difficulty to make a selection to comprise the twelve best. Those who intend adding to their collection cannot, however, do

wrong in choosing Pantheon, which in habit of growth and floriferousness leaves nothing to be desired. It is by far the best of the salmon-coloured varieties I have hitherto grown.

J. CORNHILL.

PENTSTEMON BARBATUS.

THIS is a particularly showy plant when grown in a good-sized group, the numerous flower-spikes, 3 feet to 4 feet in height, holding their drooping orange-scarlet blossoms, set at some little distance apart, having a very gay appearance even at a distance. Commencing to bloom in July the plants continue to flower from their side shoots well into September, and thus are valuable in the garden for many weeks, while for indoor decoration the tall, graceful, brilliant-flowered spikes are ever welcome, since, arranged with a few Grasses in tall vases, they create a bright and artistic effect.

The form known as *P. barbatus Torreyi* is rather more vigorous than the type, and is preferred by some, while *Pentstemon mexicana*, so-called, is evidently only a variety of *P. barbatus* with deep rose blossoms, though it is said to be a more consistent flowerer than that species. These *Pentstemons* are far better known in gardens under the name of *Chelone*, by which they were formerly universally recognised. All three varieties are well worth growing, and are, indeed, amongst the best of herbaceous plants. They are practically hardy and need no winter protection.

S. W. F.

COREOPSIS GRANDIFLORA SUPERBA.

THE usefulness of the old *Coreopsis grandiflora* is so well known that an improved form is certain of a welcome. This is of continental origin, and appears to me to be a hybrid between *C. grandiflora* and *C. lanceolata*. Its leaves more

resemble the latter plant, but they are slightly lobed, especially those formed at the base. The flowers are very freely borne, and they have the disc of *C. grandiflora*, and markedly plicate and deeply-cleft petals of a deeper colour toward the centre, so that the flowers appear star-like, and are very full and showy. It is a pretty variety, the star-like outline and "expression" of the flower—if I may use such a term—is very real. It is probably not constant from seeds, but there is no difficulty in rooting cuttings at this season.

G. B. M.

LILIUM JAPONICUM COLCHESTERENSE.

THIS beautiful Lily comes from Japan, and is generally known as *L. odorum*, a name its delicious fragrance has earned for it. It is closely allied to the well-known *L. Brownii*, and is even more vigorous than that popular sort. The bulbs are white and fleshy, and are unusually susceptible to injury from damp and cold, hence the presence of low-growing shrubs, such as shown in the illustration, around the plants is necessary to hold the balance of moisture at the root. The bulb formation, texture of the leaves, and the masses of roots that issue from the stems all indicate a habitat amid scrub, and the marvellous wealth of flowers depicted in the accompanying illustration is only possible when such intelligent association of Lilies with other garden plants is well carried out. The flowers of this Lily are exceedingly handsome, measuring 8 inches to 9 inches long and 6 inches across the richly cream-tinted funnel. A beautiful clear yellow suffuses the throat of the flower, and the outside is irregularly flushed with brown. Grown under glass, this brown colouring gives place to a light green, and the whole flower is cream-tinted. I have seen six flowers on single stems many times, and more may be possible with well-grown established roots. One cannot grow this Lily well everywhere, but in shrubberies, beds of *Rhododendrons*, *Bamboos* and grasses—all cool and sheltered—the Colchester Lily is grand, and as long-lived as any. Half the trouble in Lily cultivation would disappear if growers would plant their bulbs where the flowers could be seen in a setting of suitable leafage. The rooting medium in such places is generally the correct one, while leaf-soil and sand around the bulbs will keep them thriving.

G. B. M.

KNIPHOFIA TYSONI.

THIS handsome plant, somewhat like *K. caulescens* in general habit, but without the stem which characterises that species, is now flowering freely in the open border at Kew. From 3 feet to 4 feet high, with a large number of glaucous-coloured leaves 2 inches broad at the base, and tapering gradually to a long point, it makes a very effective border plant. Although it has been in its present position for two mild winters, being almost an evergreen, it is doubtful if it would stand a severe one without being well covered up with Bracken or dry leaves. The flower-stems are stout, and bear dense racemes 6 inches to 9 inches long and about 3 inches in diameter. In the bud stage the flowers are dull red, but on opening are streaked with yellow, eventually

LILIUM JAPONICUM COLCHESTERENSE AMONG SHRUBS.

losing all trace of red. A native of East Griqualand, seeds were received at Kew in 1899, flowering for the first time in September, 1903, but not so freely as it is this year. Other interesting members of this family in flower are *K. breviflora*, a graceful little plant from the Orange River Colony and Natal, where it is found at 5,000 feet to 6,000 feet elevation. The numerous leaves are very narrow, while the flower-stems are slender and freely produced, bearing close heads of yellow flowers. The stamens of these are slightly exerted from the mouth of the tube. *K. citrina* is a rather stronger growing plant, with lemon yellow flowers, from the mountains north of Grahamstown. This last species was introduced by Herr Max Leichtlin in 1893, but is still rare in gardens, although its distinct colour is a recommendation. Like many of the other smaller growing species it suffers a good deal during the winter, and requires well covering up with some light material. W. I.

COLCHICUM GIGANTEUM.

THOUGH not the largest flowered member of this useful and ornamental family, the flowers of this plant present a very sturdy appearance and are of good substance. They are borne on stout tubes which hold them erect. Introduced into cultivation by Herr Max Leichtlin in 1901, it is becoming more plentiful, and promises to be a favourite plant. It is evidently only a well marked variety of the older *C. speciosum*, and there is a specimen in the herbarium of a plant from Amasia in Asia Minor, which flowered with Sir Michael Foster in 1894, and which is identical with *C. giganteum*. *C. giganteum* differs from *C. speciosum* in having shorter and broader segments, over 1½ inches wide in the broadest part. The apex of the segments are also more rounded instead of being acute as in the more typical forms of *speciosum*. Without the tessellation which is characteristic of many of the Meadow Saffrons, the colour of the flower is of a soft rosy purple, with a few darker coloured spots scattered over the surface of the segments. Like *C. speciosum* it has also a lighter base, but hardly so pronounced as in that species. When it becomes common enough it will form an addition to the comparatively few autumn flowering bulbous plants available for the wild garden or margins of ponds. W. IRVING.

NEW AND RARE PLANTS.

ODONTOGLOSSUM CRISPUM XANTHOTES.

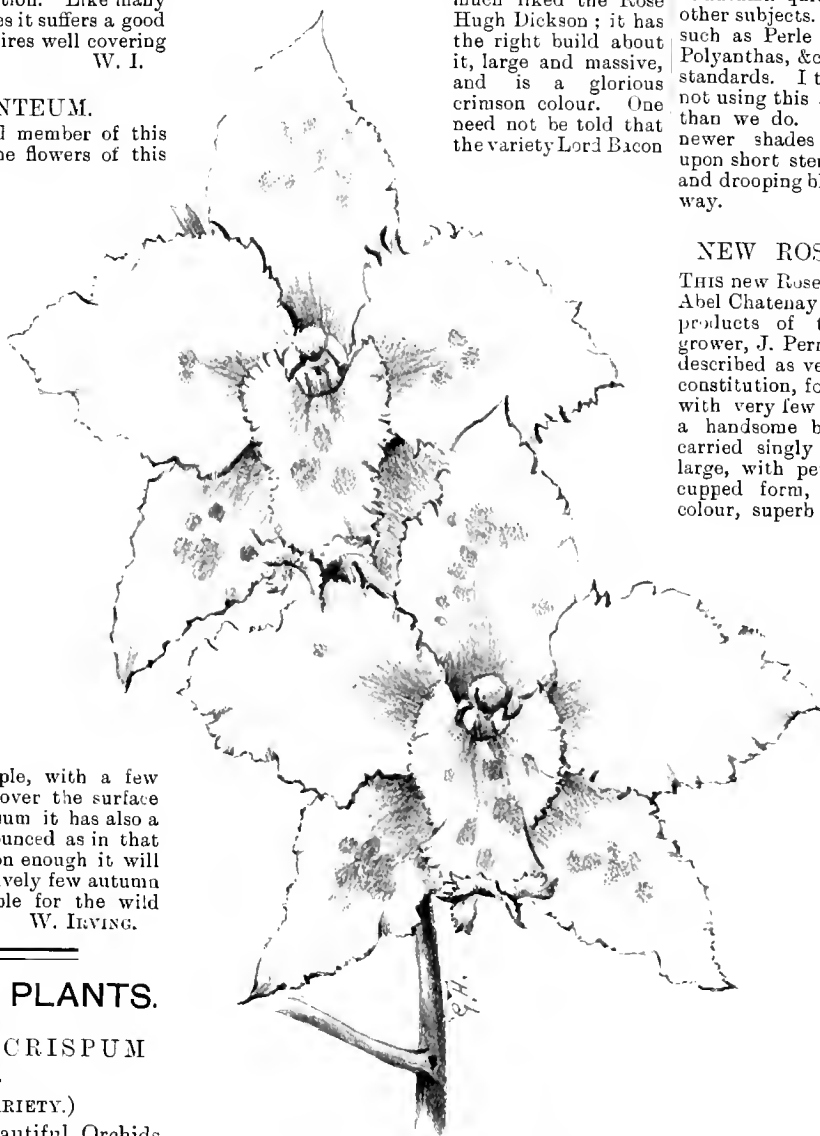

(CHARLESWORTH'S VARIETY.)

ONE of the most beautiful Orchids seen at any recent exhibition is this form of *Odontoglossum crispum*, shown by Messrs. Charlesworth and Co., Heaton, Bradford, York, before the Royal Horticultural Society on the 20th ult. The Orchid committee gave it a first-class certificate. It has a white ground which is rather heavily spotted with amber-yellow on the sepals and less so on the petals. The lip is long, with frilled edges; it, too, is white with amber blotches, while that part beneath the column is a lighter shade of yellow. The form of the flower is perfect. Messrs. Charlesworth are to be congratulated upon the introduction of such a beautiful Orchid.

THE ROSE GARDEN.

ROSE HUGH DICKSON.

IF this grand Hybrid Perpetual proves to be generally as good in autumn as was shown at the Royal Horticultural Hall recently, it will be very acceptable. Our greatest need now seems to be a crimson autumnal Rose that possesses also quality of blossom. Massing Roses that do not possess this latter quality will soon weary the average grower. What we want is a Rose as free, showy, and vigorous as *Caroline Testout*, with the indispensable charm of sweet fragrance. I much liked the Rose *Hugh Dickson*; it has the right build about it, large and massive, and is a glorious crimson colour. One need not be told that the variety *Lord Bacon*

ODONTOGLOSSUM CRISPUM XANTHOTES (CHARLESWORTH'S VARIETY).

(Natural size. Given a first-class certificate at the meeting of the Royal Horticultural Society on the 20th ult.)

was one of the parents. It portrays this fact in growth and in blossom, only that the free blossoming habit has been produced by the pollen parent, which is a *Grüss an Teplitz* seedling. It seems very remarkable that so few of the new Roses are scarlet or crimson. We appear, however, to be on the eve of quite a harvest in crimson Roses for autumn blooming. They will need to possess good brilliant colouring, free from the bluish taint that mars Roses of the *Liberty* and *W. F. Bennett* type. We want the glorious colour of *Louis van Houtte* imparted to our Hybrid Teas and a blossom of equal merit. *Hugh Dickson* seems to me to possess

some of these good points, but I can only judge from the cut specimens seen at the show. P.

POLYANTHA ROSES AS DWARF STANDARDS.

SOME of the newer dwarf Polyantha Roses are delightful when grown upon short standard Briars. One variety, *Katherina Zeimet*, has been very beautiful just lately with its fine spreading head of tiny snow-white flowers, which are as regularly formed as a *Ranunculus*, and in the mass have a charming effect. A groundwork of *Perle des Rouges*, freely planted so that the soil is not seen, would make a floral picture in early summer, and, again, in autumn quite equal to any effect produced by other subjects. Some of the other Polyantha Roses, such as *Perle d'Or*, *Eugenie Lamesch*, *Gloire des Polyanthas*, &c., are well worth growing as dwarf standards. I think we miss many pretty effects in not using this and kindred types upon stems more than we do. The Monthly Roses, especially the newer shades of colour, are really delightful upon short stems; their somewhat drooping heads and drooping blossoms are made the most of in this way. P.

NEW ROSE ETOILE DE FRANCE.

THIS new Rose, the result of a cross between *Mme. Abel Chatenay* and *Fischer Holmes* is one of the products of that well known and able Rose grower, *J. Pernet-Ducher*, of Lyons, France. It is described as very vigorous in growth and of robust constitution, forming upright bushes of large size, with very few thorns on the branches; foliage of a handsome bronzy green colour; buds long and carried singly on stiff, erect stems; flower very large, with petals of good substance, magnificent cupped form, very full and expanding freely; colour, superb velvet crimson, the centre of the bloom vivid cerise. The flowers are very fragrant and last well.

This new variety has inherited from the seed-bearing parent, *Mme. Abel Chatenay*, its wonderful habit of growth and free-flowering qualities, and from the pollen parent, *Fischer Holmes*, it has derived its brilliant colour. It is claimed for *Etoile de France* that it is the queen of ever-blooming red Roses, the best red Rose for forcing under glass for cut flower purposes, and the most vigorous and free-blooming Rose ever introduced. It was awarded a gold medal at the International Horticultural Exhibition at Turin, Italy, May 12, 1904, and a first-class certificate of merit by the National Horticultural Society of France, May 25, 1904. — *Gardening (America)*.

ROSE THE BRIDE.

FROM the first introduction of this grand Rose it has been a favourite with me. I have in my room now a fine bloom that was cut nine days ago and it is still quite fresh, while its shape is as good as on the day it was brought to me. I consider it the best of all white Roses to stand. It is very free-flowering, and when one has a stock of plants and so can choose good sound buds for propagating, it is an excellent grower. I think that the chief cause of many good new Roses being discarded before they are thoroughly tried is owing to their being over-propagated. The *Bride* is an example of this, as during the first few years of its being in commerce it was a weakly grower compared to what it is now. The same remarks apply to that grand Hybrid Perpetual *Alfred K. Williams*, to *Mrs. John Laing*, and others. R.

GARDENING OF THE WEEK.

FLOWER GARDEN.

PROPAGATING SHRUBS.

CUTTINGS of many hardy shrubs root readily if inserted out of doors at the present time. The selection of growth for making the cutting requires some little care and judgment. When possible the shoots from only healthy plants should be employed, at the same time choosing the growths of medium texture. Stout, sappy growths rarely root freely, nor do those which are thin and wiry. The cuttings should also be typical of the shrub at its best—that is to say, those of variegated or golden-foliaged shrubs, such as *Euonymus*, should be well coloured and have the characteristic markings, and be free from any tendency to revert to the green-leaved types. The cuttings root best when of good length; 9 inches long is better than 4 inches. Many err in this respect; short cuttings cannot be firmly inserted, and they are displaced by the first moderate frost. A border on the north side of a low hedge is usually a good position. The soil must be well drained and contain a good proportion of leaf-mould and sand or grit. The dibber is often used for inserting the cuttings, but the spade is more expeditious and probably better. After the bed has been made moderately firm and raked the rows should be marked by stretching the line or laying the garden staff. The soil is removed by the spade to the required depth, keeping a straight edge by the line or staff. The cuttings are placed in the rows against the upright edge, and the soil placed firmly around them. The distance in and between the rows will vary with the size of the cuttings, but it is well to allow plenty of room in the rows for the hoe to be plied.

ROSES.

The Rambler Roses, Hybrid Perpetuals, and nearly all the hardier kinds will root freely under these conditions. With Roses long cuttings are best, and rather more care in making a clean cut is necessary. Fairly stout shoots should be selected, and for preference those from which blooms have been previously cut.

CONIFERS.

These are somewhat uncertain subjects. Occasionally a fair number will root, and at others the proportion is very low. As a rule, the *Retinosporas* are the easiest. I have been the most successful with conifers, as a whole, by inserting the cuttings in boxes and placing them close by the foot of a north wall, away from all sun, and of course free from any drip.

LAYERING.

This method is often successfully employed with choice shrubs and Roses, as well as those which are difficult to root. Some fresh soil is usually necessary, and the growth should be firmly pegged down.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

BULBS TO BE POTTED.

THOSE that were potted early, as previously advised, are making good progress in growth, and require to be lifted out of the sand in which the pots were plunged. After placing them for a few days in a subdued light until the growth assumes a green colour afford them all the light and air possible, and at the same time soak the soil about their roots well with water. All the midseason and late kinds are now being potted up and treated similarly to those potted earlier. Those to be forced mainly for cut flowers should be put in shallow boxes, as then a much greater quantity can be accommodated, and the labour in attending to their requirements is considerably reduced. In the latter case a few rough leaves or lumpy loam only is necessary as drainage, but the pots in every instance should be well drained. If the soil used in potting is rather light and dry give a good soaking with water before plunging in the sand.

Narcissi especially do best in a moist, cool soil. As growth advances afford them abundance of air.

MALMAISON CARNATIONS.

While the layers are now rooted and ready for potting up those that were potted earliest are advancing in growth, and are quite ready for repotting into 7-inch and 8-inch pots, and in these they will flower. Get them well established in the new soil before the dull, dark days of winter. Carefully stake the shoots of the second year plants to admit air and prevent their getting broken. The greatest care should be observed in applying water to the roots until spring; indeed, the application of water to the roots of newly-potted plants will for some time be unnecessary.

EAST LOTHIAN AND INTERMEDIATE STOCKS

are ready for pricking out 2 inches apart in boxes, or where there is plenty of convenience put them in pots singly and place them in a close cold frame until they re-establish themselves. Keep the interior of the frame dry, and fumigate occasionally to keep green fly in check.

CINERARIAS

not only requires an abundance of air to prevent the leaf-stalks getting drawn, but their crowns will develop better if they are given a position close to the glass to obtain the benefit of the light. Although *Cinerarias* grow the best in a cool, moderately moist soil, a mistake is often made at this season in keeping the soil about their roots too wet.

PRIMULAS.

The earliest of these are now showing flower-spikes, and will derive great benefit from an occasional dose of liquid manure or soot water. Afford them a good supply of air and light, with a moderate supply of water at the roots.

J. P. LEADBETTER.

The Gardens, Tranby Croft, Hull.

FRUIT GARDEN.

MELONS.

THE weather has been most favourable to the growth and ripening of late Melons. When ripened without the aid of sun they are of poor flavour and of little value. A rather dry, warm atmosphere must be kept during the time the fruits are ripening, otherwise they are liable to split. Thin and stop the growths, and take advantage of bright sun to ventilate freely in the early part of the day when the fruits are colouring. Later plants whose fruits are developing must receive no check. Do not use the syringe too much at this season; moistening the paths and borders is sufficient. Keep a steady bottom-heat and a night temperature of 70° at 10 p.m.

CUCUMBERS.

Sow seeds if this has not been done. Planting Cucumbers is often delayed, owing to the house being occupied with late Melons. If the latter do not promise to be satisfactory they should be cleared out to make room for the Cucumbers. Grow the plants sturdily, and keep down insect pests; pick off all the flowers, and allow the plants to grow well before they bear fruits. A steady bottom-heat is essential during the winter months, whether obtained by hot-water pipes or fermenting material. A night temperature of 70°, falling to 65°, is suitable now. Avoid a close atmosphere by careful ventilation, stop and remove all exhausted growths, and do not overcrop the plants. Give light top-dressings of rich soil, warming the soil well before using. Give occasional waterings of warm weak liquid manure, and see that the plants are not infested with spider, thrips, or fly.

STRAWBERRIES.

Plants for forcing next season have now filled their pots with roots. Give plenty of space to each plant, so that the crowns may become well matured. Remove all runners and weeds as soon as they appear. Give weak manure water to all plants that require it, care being taken not to overfeed strong leafy plants which are inclined to grossness.

WINTER TOMATOES.

Plants required to provide fruits during the winter months now need more warmth and less air and

less moisture at the roots. A warm atmosphere is essential for the setting and the swelling of the fruits at this season. Remove the side growths, and fertilise the blooms daily with a soft brush. Where young growths have been trained in on late summer plants a good set of fruit is often secured. These plants will continue to supply good fruits if they are clean and not exhausted.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

LIFTING CARROTS, &c.

DURING the present month this will be important work. An effort should be made to have the various crops lifted before severe frost sets in, and as long as there is a prospect of a continuation of this dry weather the work of lifting can be performed much more comfortably. All varieties of Carrots for the main supply should now be lifted. Carrots do not improve from being left in the ground after this date. Those sown in July and August may be left for some time yet. Should they be lifted too early the roots may shrivel. The main crop should be lifted carefully with a fork and allowed to dry before storing. They may be stacked in the same manner as advised for Beet. Care should be taken not to cut off the tops too near the crown. The store-house should be cool and dark.

SALSAFY

is still green and growing, and must be left for some time yet. Parsnips may be left till the end of the month.

CARROT PLOT.

As soon as the Carrot crop has been cleared the preparation of the plot for another season should be begun. Liberal dressings of soot should be placed on the ground as it can be procured. Fairly good Carrots have been grown on a plot that has been treated with fresh sea-sand, and also on ground that has been liberally dressed with wood ashes. Both are reliable aids for the production of this useful root. When time allows sand and wood ashes should be placed on the ground and every effort made to have all in readiness for trenching before frost sets in.

LETTUCE.

As this is always in demand, plants that are well advanced should be lifted with a large ball of earth and placed in cold frames for use during the winter. They should be kept near to the glass and given plenty of air. Watering should be done very sparingly and the leaves kept dry, or decay will soon set in. Plants from the last sowing will now be ready for pricking into frames. Choose the largest of the plants; the remaining ones may be left as sown, and in a warm situation may stand the winter and prove useful in spring. Remove all decayed leaves from full-grown plants and see that they are not too thick in the rows, as at this date the plants damp off rapidly.

Hopetoun House Gardens, South Queensferry, N.B.

THOMAS HAY.

ORCHIDS.

LÆLIA PURPURATA.

THIS grand old species is now starting into growth after having rested since the flowering season. If the plants have not many back bulbs and only require potting I prefer to wait until the growths have made more progress and collar roots are formed. When a large specimen shows signs of deterioration, I advise that it should be attended to at the commencement of growth. In cutting away the back parts do not retain more than two pseudo-bulbs behind the leading one. If this is carefully done little injury to the live roots will follow. Ordinary pots should be used, having them half full with rhizomes. We have found great benefit accrue since we used rhizomes in the place of crocks with most *Lælias* and *Cattleyas*, and especially with the above-named *Lælia*. The compost should consist of two parts each of peat and sphagnum and one part of leaf-soil, with some coarse sand and small crocks added. Pot moderately firm, keeping the base of the leading growth rather lower than the rim of the pot. Keep the new leads as

far as possible away from the edge of the pot. Leave sufficient room for a surfacing with sphagnum. Water should be applied very sparingly; damp freely between the pots. In no case try to force them; the best results are obtained by encouraging hard sturdy growth.

SPATHOGLOTTIS.

Aurea, kimballiana, Veillardii, and the fine hybrid aureo-Veillardii are either in spike or in flower, and water should still be freely applied. The flowers last longer if the plants are kept in the moist and hot house in which they are grown. Those not flowering are now starting into growth, and potting may be done. They prefer a fairly retentive compost, such as one made up of two parts fibrous loam, one part leaf-soil, and one part sphagnum, with a good quantity of small crocks and coarse sand. Pot firmly, surfacing with sphagnum. They are easily propagated by division, and revel in much heat and moisture, so a shady position in the hottest house should be given and the surroundings kept moist except on dull winter days. They will benefit by being sprayed overhead throughout the year, and at no season should they be allowed to get dry at the roots. Ordinary pots are preferable to any form of receptacle that allows the free admittance of air to the roots. Give a good drainage, so that the free supply of water afforded does not quickly sour the compost.

Gatton Park Gardens, Reigate. W. P. BOUND.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

LILIUM SULPHUREUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This is a very distinct and beautiful Lily. It was introduced by Messrs. Low and Co., and first exhibited by them before the Royal Horticultural Society on June 25, 1889, under the name of *L. wallichianum superbum*; it was then unanimously voted a first-class certificate. About this time considerable discussion took place in the horticultural Press as to the right name of this plant. In *THE GARDEN* of April 19, 1890, a coloured plate was given of it under the name of *L. nepalense ochroleucum*. In the *Gardeners' Chronicle* for 1891, part II., it is described by Mr. Baker under the name of *L. wallichianum superbum*. Eventually it was given specific rank and figured in the *Botanical Magazine*, t. 7257, under the name of *L. sulphureum*. Its most distinct character is the possession of bulbils in the axils of the leaves. It varies considerably in height; out of doors 5 feet to 6 feet is about the average. Under glass it often grows to a height of 10 feet or 12 feet if planted out. The flowers, two, three, or four on each stem, are slightly pendent, about 9 inches in length, and 7 inches or 8 inches in diameter at the mouth. The interior of the tube is yellow, fading to creamy white at the tip. The exterior is usually tinged with red, more especially in those grown in the open. It is very fragrant. It is found growing on the hills at a considerable elevation in Burma, and seems likely to succeed well in the open in many parts of the country. A very good place for planting it is among *Rhododendrons* if not too crowded. For a comparatively new Lily the price is very low, but this is no doubt due to the ease with which it is propagated from bulbils. These should be removed from the stems soon after flowering, dibbled in shallow boxes, and placed in a frame where frost is excluded. The second year they should be transferred to a bed in a sheltered position outside or where a frame can be placed over them in winter. They will flower in from three to four years. A. O.

POTATO PROSPECTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The National Potato Society's Great Exhibition at the Crystal Palace is near at hand, as it falls on the 11th and 12th inst., but the late Potato

breeders present not the least evidence of ripening, and at the present moment there are literally tens of thousands of acres in the kingdom where the plants are not only green but are even still blooming. Whatever may be the customary condition of the Potato crop at this time of year in the north, certainly it presents unusual aspects just now in the south. If appearances are to be taken as clear indication of what the tuber crop will be, then of late varieties of the Up-to-Date type there should be an enormous crop. But tops do not always clearly evidence the nature of the roots, hence only time can reveal the condition of the tuber crop. The present need of Potatoes is a spell of several weeks of fine dry weather, with mild frost to check further growth and compel the tubers to harden their skins. Trade and other growers who contemplate showing largely at the Crystal Palace late sturdy varieties are troubled lest on lifting their crops they will find the skins still thin and tender. That may not be a serious trouble so far as marketing is concerned, but it does adversely affect the appearance of tubers on the exhibition table. Such varieties as Northern Star, Eldorado, King Edward, The Factor, The Diamond, Lim Gray,

THE SPRING SNOWFLAKE IN A SURREY GARDEN.

Discovery, and many others of the newer or more popular varieties, even in the south, are still growing vigorously. It may be for that reason that perhaps medium or second earlies will make the best appearance at the Potato show. In any case a most remarkable show is certain, and the attendance of Potato growers will be a record one. A. D.

TROPÆOLUM SPECIOSUM AND LOGANBERRY IN SWEDEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—After three years' trial I have succeeded in flowering *Tropæolum speciosum*. I have planted it on the north-west side of a *Pterocarya caucasica* on a lawn. Could you kindly inform me if it is hardy, or must I shelter it during the winter? The temperature is not often as low as -4° below zero Fahr., but we often have a spell of about 15° Fahr. Would you further inform me if there is any chance of growing the Loganberry here out of doors without protection during winter? I understand that it is successfully grown in British

Columbia, where I should think the winter must be very severe.

Wicks Gard, Wadsbro.

[Both should succeed in Sweden. We publish the note in the hope that someone with experience will also help our correspondent.—Ed.]

FRUIT IN LINCOLNSHIRE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I enclose a cutting from the *Yorkshire Telegraph and Star*, which shows the state of affairs in the fruit-growing districts of Lincolnshire. I have no doubt it will prove of interest to some of your readers. "Apples at Twopence a Stone.—A number of Lincolnshire fruit-growers have entered into contracts to supply Apples at $2\frac{1}{2}$ s. per ton, the price to include gathering the fruit and putting on rail. One Spalding dealer is despatching fifty tons of Apples at this figure, the fruit going to Cumberland for the purpose of making cider."

Totley Hall Gardens, Sheffield. D. LEWIS.

IMPORTING JAPANESE PÆONIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I wish to state again that an English Phylloxera certificate has no value at all, and that not even a Consul has the right to issue such a document. With few exceptions plants can be introduced to Germany by addressing the packages—which must be boxes, not hampers—to an agent at Hamburg, and giving him notice of the address of the final receiver. The agent calls for and pays the expenses of the expert, and forwards the box to its destination.

Baden-Baden.

MAX LEICHTLIN.

LEUCOJUM VERNUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I send you a picture of the spring Snowflake growing in a woodland garden in West Surrey. It is a charming little plant for the rock garden, and here under large trees it thrives well. Probably it benefits by the leaves which fall and enrich the soil. WEST SURREY.

A NOTE FROM MANITOBA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I receive *THE GARDEN* regularly every week; it reaches me two weeks from the date of issue. I am always pleased to get it, as I learn so much about the various flowers, plants, shrubs, and trees that I am interested in. I often think how delightful the Old Land must be with all its gardens, parks, and beautiful grounds. In Western Canada we are trying to grow many of these beautiful things too. We had an excellent display of flowers, &c., at our annual exhibition recently held in the City of Winnipeg, Manitoba. A very good account of it appears in the September number of the *Canadian Horticulturist*. I thought you would like to hear something of what we in this far-off north-western part of the British Empire are doing along the lines advocated by *THE GARDEN*.

H. HARLEY.

Swan River, Manitoba, Canada.

CACTUS DAHLIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The Dahlia exhibition season is now nearly over, and so far it has been an excellent one. Flowers of all sections have been exceedingly good, and Cactus varieties, those which command most admiration, have been evolved to a degree of excellence beyond which in relation to the present accepted form of Cactus flowers it seems to be impossible to go. The new flower of the year is without doubt J. B. Riding, but many others, both old and new, are so beautiful in form and colour as to leave none standing out with exceptional excellence. A serious drawback to so many of the new and singularly beautiful varieties, especially those grown under favourable conditions of position and climate, is that they are never seen in the same superb form elsewhere later on. Many growers make that complaint, and no doubt it is

GROUP OF DOUBLE SEEDLING BEGONIAS.

for that reason that those which receive the honour of certificate awards are so seldom seen later. Committees of societies have of late been exacting from seedlings a higher standard of excellence—a matter for congratulation; but they have made no conditions as to constitution or habit. Hence scores of varieties honoured as seedlings with awards have been put on the market and have been failures. Constitution and general floral excellence should be taken into consideration before awards are made. Then, in relation to Cactus Dahlias as garden flowers, so little is done to encourage them. Certainly at the recent Earl's Court show classes for flowers in vases without any form of artificial support were found, and they were well filled. It was possible thus to see that there are varieties in commerce having fairly stout, erect stalks, but how few of these are to be found among the certificated ones. Some also had very short terminal stems. These vase classes indicate a step in the direction of encouraging the production of stiff, erect-stemmed flowers, but we do not find awards made to habit, but solely to beauty of bloom. The Cactus Dahlia still is rather a victim of the exhibition stand; hence its value as a garden or decorative plant is regarded as of very minor consideration by exhibitors. Yet to many Dahlia-lovers decorative effect in the garden is the primary consideration. When show, fancy, Pompon, or single Dahlias are concerned, no question as to garden habit arises, because those are in all cases known, and are always good. It is strange that the wonderful blooms of shows and fancies, not inaptly, all the same, described as lumpy, should after all be more conspicuous and effective in gardens than are the most perfect and beautiful of Cactus sorts. As to Pompons, they are amongst Dahlias inimitable garden flowers, and singles bloom almost too profusely. Whether from seed or from cuttings, plants now are generally dwarf, bushy, and marvellously floriferous. Raisers of Cactus Dahlias must begin to realise that if these are to continue widely popular habit and constitution must have the highest consideration. A. D.

LILIUM SPECIOSUM FASCIATED.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Enclosed are two small photographs of *Lilium speciosum* roseum which apparently by a freak of nature has a flat stem measuring $1\frac{1}{2}$ inches across at the top and bearing fifty blooms. It has been grown by Mr. Chalcraft of Dorking, who

annually has a large consignment of this variety, but has never before seen one develop its growth in such a curious manner.

CHARLES W. CROSBY.

[The photograph of the fasciated stem of the *Lilium* was unfortunately not suitable for reproduction. We have seen several instances of fasciation in Lily stems this year.—ED.]

SPIRÆA GIGANTEA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The illustration on page 174 well portrays this giant *Spiræa*; it is one of the noblest of the genus, and especially suitable for the waterside. In the gardens at Westwick Hall in Norfolk I recently saw a fine group of this *Spiræa* growing on a north-west border. The growth was fully 8 feet high and the flower-heads of huge size; it certainly enjoyed the sandy peaty soil of this garden, which is so favourable to hardy plants generally.

E. MOLYNEUX.

NURSERY GARDENS.

MESSRS. BLACKMORE & LANGDON'S TUBEROUS BEGONIAS.

CLOUR in the flower garden is all important nowadays, and largely for this reason the tuberous Begonia has leaped into popularity. There can be no doubt about its being in high favour with both amateur and professional gardeners, for beds and borders in public parks and private pleasure grounds, city window boxes, and suburban gardens are bright with a brilliant and continued colouring that was unknown in the palmiest days of the zonal Pelargonium. But to gain some idea of the value of the tuberous Begonia as a summer flower, to realise the wealth of colour and the infinity of shades and tints that its varieties possess, and to have before one unmistakable evidence as to its floriferousness and the persistence of the blooms, one must see

A BEGONIA FARM,

and such a term may be not inaptly applied to the nurseries of Messrs. Blackmore and Langdon, which are situated on Twerton Hill, overlooking the ancient town of Bath. Immediately upon

entering the nursery gates you are confronted by a mass of colour that only the tuberous Begonia can give at this season of the year; planted in long narrow beds, with just a small pathway between them, they make

RIBANDS OF RED AND YELLOW, and white and pink and scarlet, and other shades of colour impossible almost to define. The flowers are held boldly and erect on stout stalks, so that their form and colouring are fully displayed. One of Messrs. Blackmore and Langdon's persistent aims in Begonia culture has been to produce flowers that are properly displayed on stout stalks, and how well they have succeeded is shown in the remarkable sight the Begonias now make in their Twerton nursery. Among the many thousands of plants cultivated here, of course, annually there are some that must be weeded out, but, generally speaking, the strain has reached a high standard of excellence through careful and continuous selection in the right direction, and it is safe to say that a packet of Blackmore and Langdon's seed will produce flowers of rich and varied colours that "look one in the face." Unless a tuberous Begonia does this it is useless from the point of view of

the flower gardener who wants to make bold masses. It is interesting to learn that this splendid display of flowers, practically from one end of the nursery to the other, is chiefly made by plants that were raised from seed sown last January. The seedlings were grown on, gradually hardened off, planted out late in May and early in June, and commenced to flower in July. Ever since they have been in flower, not one or two here and there, but

TUFTS OF BLOSSOM,

and they will remain rich groups of colour until the frost spoils their beauty. And not only in the mass are these Begonias very beautiful, but the individual flowers will bear looking into, so exquisite is the form and attractive the colouring. It is not difficult to find among them blooms that are of such perfect shape and beautiful tints as to be comparable only to Tea Roses or Camellias. This is no imaginative picture, for the clearly-biselled pure-tinted tuberous Begonias of to-day are very different from those of a few years ago. We saw some that could be more accurately likened to a *Nymphaea* than any other flower, so broad and thick were the petals. And then the variety of forms to be found among them—

SINGLE, DOUBLE, CRESTED, FRILLED, AND FRINGED—

all these are now recognised by Begonia growers, while of the shades of colour that are represented the pen fails adequately to give an impression. They must be seen to be appreciated. But in Messrs. Blackmore and Langdon's nursery, even more striking, perhaps, than the multi-coloured riband beds, are those devoted to the best-named varieties, each planted separately. They make a wonderful show; not an inch of soil is to be seen between the plants, and far fewer leaves than flowers; in fact, in one or two instances the beds were literally

HUGE POSIES OF FLOWERS,

and the colours bright, clear, and distinct. These are specially selected named bedding varieties, and have to be increased by cuttings, for, of course, they could not be relied upon to come absolutely true from seed. As showing the different results obtained by a natural method of propagation, i.e., by seed and by an artificial one, viz., by means of cuttings, many thousands of fine plants in flower raised from seed sown early in the year were pointed out in contrast to those raised from

cuttings last year, the nine months old seedlings were much finer plants than the eighteen months old cuttings. An interesting point about the masses of named bedding varieties is that the tubers were not started in heat, but were planted direct in the beds early in May, and the plants began to bloom in mid-July. The most important point in the successful culture of tuberous Begonias is to

KEEP THEIR ROOTS COOL AND MOIST.

The flowers drop quickly if the roots are in dry soil. Directly after planting the surface should be mulched with cocoa-nut fibre or peat moss litter, preferably the latter, for it acts as a manure also. Among the many splendid named varieties we saw, and that are unsurpassed for massing, are the following, which can be confidently recommended: Marquis of Stafford, deep crimson, very free; R. B. Parsons, deep pink, very fine; Argus (which received an award of merit from the Royal Horticultural Society's floral committee on the 6th ult.), bright scarlet, a dwarf but vigorous grower; Gladiateur, the finest crimson bedder; Calliope, a beautiful light pink flower of very good form; Hollyhock, pink, very free; Mrs. French, wonderfully profuse, creamy white; Hilda, salmon; Lord Langton, bright scarlet; Orion, orange-scarlet; and Rev. E. Lascelles, yellow. A new bedding Begonia called Bavaria (award of merit, Royal Horticultural Society), has single rosy carmine flowers, freely produced on dwarf bushy plants. Among the new double Begonias for 1904 are John Milburn, dark glowing crimson: Avalanche, pure white; Countess of Warwick, perfectly formed flowers of bright orange colouring; Winnie Cook, salmon pink; Mrs. M. B. Castle, large blush, reverse of petals pink; Mrs. E. W. Smith, salmon; Polite, light rose-pink; all of exceptional merit. We might justly write much more about the tuberous Begonias, but we must say something also about

THE CARNATIONS,

of which Messrs. Blackmore and Langdon have a very fine collection. They grow some 100,000 plants in many beautiful varieties. Of these we might specially mention the new border Carnation Alma, a Clove-scented crimson of vigorous growth, which received an award of merit from the Royal Horticultural Society in 1903. Master F. Wall is another border sort that should be in every garden. It is a large blush white flower, and the plant is a strong grower. The Hon. Lady Neeld is a beautiful yellow ground fancy flaked with lavender, orange, and white. William Tylee, a rich yellow ground fancy, marked with rich crimson and purple, is very handsome, and so are Rosina, bright rose self; Mrs. Wall, large yellow ground fancy, streaked with lilac rose; Richness, one of the brightest and most handsome Carnations in cultivation (first-class certificate from National Carnation and Picotee Society, July, 1903), yellow ground fancy, edged and striped with scarlet; Mrs. Rotherham, buff ground fancy, edged and flaked with lavender; and Mr. J. Pitts, yellow ground fancy, edged and marked with rose. Of Tree Carnations Messrs. Blackmore and Langdon think most highly of Enchantress of flesh-pink colouring, one of the finest of the American varieties. With a brief allusion to the Cyclamens and early-flowering Chrysanthemums,

SOME 10,000 VIOLET PLANTS,

are grown, among them being the new varieties Pearl Robe, reddish purple; Mr. Leopold de Rothschild, similar to but said to be finer than Luxonne; and Mrs. Arthur, a double flower of rather deeper colour than Lady Hume Campbell; the same number of Polyanthuses, an excellent plot of

Strawbery St. Antoine de Padoue, from which many delicious fruits are gathered daily, and two Potatoes that are remarkable for their cropping qualities, viz., Duchess of Cornwall and Conquering Hero. We must conclude our notes about Twerton nursery. Tuberous Begonias and Carnations are chiefly grown there, and, as usually happens when skill and care are concentrated in one direction, they are grown uncommonly well.

A GENERAL CALENDAR.

FLAME FLOWER (TROPÆOLUM SPECTOSUM).—This gorgeous climber is doing better in Norfolk this season than ever I remember to have seen it, and when it is happily placed it is one of the most interesting plants imaginable. It thrives best in a deep rich alluvial soil, consisting largely of leaf-mould and loam. Old potting soil suits it well; it prefers a cool, moist, and rather shady position, and should be sheltered from strong winds. Now is the best time for transplanting it, for if done before the soil loses most of its warmth the fleshy roots will soon establish themselves. On the other hand, if left until a later period I have invariably found that they go mouldy and soon rot away.

Wallflowers.—These are among the most indispensable flowers we have. A few dozen of the best plants of the earliest sorts should now be potted up, press the soil firmly, and give the plants a good watering. Then place them in a cool frame and keep close and shaded for a few days. When the plants recover a little air should be given, and the lights may soon be taken off altogether; the plants should be kept in a cool greenhouse through the winter months, then in the early spring they will yield a wealth of fragrant blossoms.

Pansies.—Where a suitable position can be given these will give an uninterrupted display the whole of the summer if attention in watering and mulching be given. Now is a good time to propagate. Cuttings 2 inches or 3 inches long should be taken from the base of the plant, where plenty of young shoots are usually found at this time of the year. Dibble them in rows 2 inches apart and give a gentle watering. Keep the frame or handlight closed for a time until it can be seen that the plants are growing, when air should be given them to induce a sturdy growth. The following

will be found useful and showy varieties: Mrs. Heale, yellow; Purple King, fine and very free flowering; Blanche, white; Countess of Hopetoun, dwarf, one of the best; Devonshire Cream, a charming variety; Primrose Dame, self; Kitty Hay, deep yellow; John Quarton, light mauve self, fine for bedding.

Hardy Fruits.—The high winds of September did considerable damage to the orchards in this district, causing a number of the fruits to fall. Striped Beaufin Apples and Catillac Pears that should have hung on the trees for at least another month were brought down. Intending planters should learn a lesson from this, and not plant these heavy kinds of Apples and Pears where the orchards are exposed to high winds. All except the latest kinds are now gathered. Of both Apples and Pears some should be allowed to hang as long as possible—such varieties as Norfolk Beaufin, Nonpareil, Easter Pippin, and other long-keeping sorts. These in sheltered places will continue to develop for some time, and will be more useful later on. The flavour of late Pears, either on walls or pyramids, is much improved if the fruit is allowed to hang as long as possible. Great care should be taken to protect the fruit from birds, as these are likely to pick holes in them, by which the wet enters, causing them to rot wholesale.

Tomatoes.—These in the open air must be carefully watched. Gather the fruit dry daily, directly it begins to change colour, finishing it off indoors. On the first indication of anything like frost, cut off or pull up the plants bodily, and hang them in any fairly warm greenhouse or shed, where the bulk of the fruit will ripen in due course.

Norwich.

T. B. FIELD.

THE INDOOR GARDEN.

TROPÆOLUM AZUREUM.

HOW seldom does one see this little greenhouse climber in good condition, indeed it appears to be almost unknown to the majority of flower lovers. It is a very old inhabitant of our gardens, having been introduced into this country from Chili in 1842. Probably one reason why this charming little climber is not so much grown as one might expect is that the growth is not by any means robust. The bulbs never come so large as those of its relative *T. tricolorum*, the

GROUP OF SINGLE SEEDLING BEGONIAS.

stems being proportionately weaker. As a natural sequence root action is much more feeble, so that great care must be given as regards choice of soil, watering, and other cultural details. Having had considerable success with its culture, I find that the soil must be such as to allow of a free root run and that would not be likely to become sour during the winter.

A compost of equal parts of loam and leaf-soil, with a slight addition of peat in small lumps, suits the *Tropeolum* well. The drainage must be very good, putting some rough material on the crocks to keep it open. For a full-sized bulb a 7-inch pot is quite large enough, as the object is to get the soil well filled with roots by the time buds commence to form. A good plan is to pot in moist soil and plunge the pots to the rims in a cold frame; in this way no watering is needed, and the soil being maintained in an uniformly moist condition roots are more freely emitted from the bulbs. I first made acquaintance with this little climber many years ago in Germany, and I thought then as I still think that it is one of the loveliest greenhouse flowers in cultivation. The flowers have not the long spur that distinguishes

the highest possible award, and it would have readily secured a first-class certificate had more particulars been furnished as to its cropping qualities.

As regards its parentage, what could be better than Ribston Pippin and Peasgood's Nonsuch. The last mentioned is a splendid Apple, but at times one of the shyest fruiters in a young state, and, unfortunately, the Ribston is none too long lived. The new Apple referred to differs from both; in size it more resembles Peasgood's; the quality, though excellent, is not much like that of the Ribston. Indeed, in my opinion it is a first-rate cooking Apple, but not suitable for dessert. The colour is pale yellow, and the shape conical, not unlike Ribston in this respect, and the flesh is very white and juicy.

As an exhibition Apple it will find many admirers, and will become a great favourite. It is certainly a distinct gain to get such a fruit, for, though we have no lack of good Apples at this season, there is none of

the summer and abundance of sunshine. We had the rainfall, but it was not light, and the other extreme in the way of sunshine, and therefore in the eyes of the pessimists the outlook for 1904 was not promising.

Nature has, however, a knack of upsetting theories when she is in the mood, and we were more hopeful as the abundance of fruit-buds noticeable on the trees was encouraging. Again, some people remembered the fact which the theorists overlooked, that the trees had enjoyed a rest. The deadly spring frosts blighted the hopes of a crop, and being free from the strain of fruit bearing the trees were engaged throughout the season in storing up a reserve of forces, which they have since been able to draw upon. Some trees perhaps grew too rank, but the pressure of this season's burden has checked them again, and in the case of many weakly specimens the spring frosts of 1903 were a blessing in disguise, because they were enabled in the wet summer which followed to make the growth necessary to their re-establishment. In short, then, last season was practically fruitless, but the trees were having a rest.

September this year is dying hard, and the month gives one the impression that it is determined to keep up the reputation of its predecessors in the way of weather, which at the moment of writing is summer-like. Everyone is agreed that we have had a glorious summer, and recollections of last year have made us appreciate it all the more. One after another the fruit crops have followed, and we have the satisfaction of knowing that there have been no real, and only a few comparative, failures. In short, Nature has been kind all the way through, and she seems to be engaged in a grand effort to make the dying days of summer the most beautiful.

Perhaps the present moment, when we are in the flush of the harvest, seems hardly opportune for discussing what may happen another season, but last year at this time it was an absorbing topic and was allowed, as it gave some ground for hope, and without the capacity for hoping gardeners and fruit growers would be poor creatures. The contrasts are great, for whereas last September we were looking back on a miserable summer, and surveying fruitless trees and empty fruit-room shelves, now we have the recollections of a delightful season, and the puzzle is to know where to store the harvest of fruit. The sun, which has shone so persistently all the summer, and has not yet lost its power, ought to do great things in ripening up the wood and ensuring plump fruit-buds, if theory is to be relied on; but the reckonings of theory, as we have already learnt, can be readily upset by the workings of Nature. The question is, Can the trees which have been and are so heavily laden this season be expected to do as much next year, even supposing that climatic conditions are favourable? This remains to be seen, but the experience of good fruit years in the past being followed by seasons of comparative scarcity seems to prove that with fruit under cultivation the strain of a heavy crop has its effect on the bearing capacities of the trees the following year.

I have recently passed through a well-known Plum-growing district, in which Victorias are largely represented, and have seen hundreds of trees simply pulled out of all shape, and laden to breaking point with fruit. A few weeks ago they were propped and tied up in various ways to prevent the branches from breaking, but now the fruit is all gathered the trees present a sorry-looking appearance. They seem to have no energy left. What effect has the enormous strain had on the trees, and can they be expected to give a similar return next year, even supposing that the climate is all that can be wished? On the face of it one cannot reasonably expect it, and perhaps it might be possible to do away with these gluts of stone fruit some years and famines in others, if the fruit, when so thickly clustered on the trees, could be thinned out to moderate proportions, as the energies of the trees would not be so heavily taxed, and there would be more likelihood of getting regular moderate crops, instead of a glut one season and a famine the next.

THE NEW APPLE REV. W. WILKS.

(Shown by Messrs. Veitch and Sons before the Royal Horticultural Society on the 20th ult., and given an award of merit.)

its congener tricolorum, and they are of a lovely blue tint with white centre. They are so different from flowers of the *Tropeolums* generally that one scarcely realises that this plant is a member of the genus.

Bylect.

J. C.

THE FRUIT GARDEN.

NEW APPLE THE REV. W. WILKS.

MESSRS. JAMES VEITCH have reason to be proud of the new Apple named the Rev. W. Wilks. It was placed before the fruit committee of the Royal Horticultural Society on the 20th ult., and obtained an award of merit owing to its excellence. Such a beautiful fruit deserved

better appearance, and its cooking qualities should make it a great favourite with growers.

G. WYTHES.

FRUIT CROPS AND SEPTEMBER SUNSHINE.

ABOUT this time last year, when September was helping the season to earn its evil reputation as being one of the wettest on record, many well-disposed persons who pin considerable faith in theories glanced at the rank, sappy-looking growths made by the fruit trees during the summer and pessimistically shook their heads at the prospect. According to the theory on which they based their calculations, unless wood is well ripened in the autumn it is unreasonable to expect a crop the following season, and in order to get wood in the desired state of ripeness it is essential to have a light rainfall during the latter half of

The force of this argument is illustrated in the case of fruit grown under the direct control of the cultivator. Take Peaches and Nectarines for instance. Suppose these trees were allowed to carry the crops under glass which thousands of fruit trees of all kinds in gardens and orchards have done this year, would they be as heavily laden the next? Of course not, and frequently when gardeners are discussing the lightness of a crop on an indoor Peach, Nectarine, or Grape Vine, do they not frequently attribute the cause to the fact that they were over cropped the previous year? Everyone knows how essential judicious thinning is with fruit trees growing under glass in order to secure regular even crops, and yet if a tree growing outdoors fails after bearing a burden which is really too great for it, one hears it put down to unripened wood or some vagary of the weather.

It seems likely, then, that to some extent at any rate the abundance of this year's fruit harvest is the natural following of last season's famine, and particularly so in the case of stone fruit. Apples are more general in their habits, and though many trees are heavily laden, where there is health and vigour there is good promise for an abundance of fruit-buds.

Still the thinning theory may be applied here as in other cases. Apples run small because there are so many on, is the general complaint this year. Just so, but in the cases where a kindly hand removed a portion of the fruit, or that common enemy, the codlin moth caterpillar, acted the part of a friend to the tree, by boring some of the fruits and causing them to fall, the remainder of the crop developed to their full proportions, and these are the specimens which at the close of September are being saved for the autumn shows and are fetching the highest price in the market.

Finally, the champions of the ripened wood theory have a grand chance of proving their arguments, as the September sunshine this year is doing all that sunshine can to help the ripening process, and how much next year's crop will be affected by it is something which remains to be seen. G. H. H.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY'S GREAT FRUIT SHOW.

DIVISION I.—GARDENERS AND AMATEURS ONLY.

Nine dishes of ripe dessert fruit, six kinds at least: First, Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle Gardens, Derby. The Pitmaston Duchess Pears, Black Hamburgh and Muscat of Alexandria Grapes, Golden Eagle Peach, and Allington Pippin Apple were excellent. A very large specimen of Melon Blenheim Orange was included. Mr. J. Lock, gardener to the Hon. Justice Swinfen Eady, Weybridge, was second, Marguerite Marillat Pear and Humboldt Nectarine being very good dishes. Mr. J. McPherson, gardener to the Earl of Londeshorough, Market Weighton, was third. There were no more entries.

Six dishes of ripe dessert fruit, four kinds at least: First, Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Chilworth Manor, Romsey. Apple Worcester Pearmain, Peach Sea Eagle, Pear Pitmaston Duchess, and Grape Pince were very good dishes. Mr. J. Dawes, gardener to Lady Biddulph, Ledbury, was second. Melon Hero of Lockinge, Humboldt Nectarine, and Pear Marguerite Marillat were well shown. Mr. W. H. Bacon, gardener to Sir Marcus Samuel, Bart., Maidstone, was third. Gros Colmar Grape and Marguerite Marillat Pear were the best dishes. There were three more entries.

GRAPES.

Black Hamburgh, three bunches: First, Mr. W. Mitchell, Chilworth Manor Gardens, with fruit splendidly coloured, although the bunches were not very shapely; second, Mr. W. Harrison, Hallingbury Place Gardens, Oxon; third, Mr. J. H. Goodacre. There were three more entries.

Mrs. Pince, three bunches: First, Mr. W. Mitchell, Chilworth Manor Gardens, with very good fruit, perfectly finished; second, Mr. W. Camm, gardener to Major Hibbert, Rugby, with large, very poorly coloured bunches. No more entries.

Alicante, three bunches: First, Mr. H. H. Brown, gardener to G. C. Raphael, Esq., Englefield Green, with large bunches well coloured, though the berries were small; second, Mr. W. H. Bacon, gardener to Sir Marcus Samuel, Maidstone, with fine bunches not so well coloured; third, Mr. W. Howe, gardener to Lady Tate, Streatham. No more entries.

Madresfield Court, three bunches: First, Mr. W. Mitchell, whose fruit was splendidly finished; second, Mr. W. Taylor, gardener to C. Bayer, Esq., Forest Hill; third, Mr. Goodacre. One more entry.

Any other black Grape, three bunches: First, Mr. W. Mitchell, who showed Gros Maroc with very large, well-coloured berries; second, Mr. H. H. Brown, gardener to G. C. Raphael, Esq., Englefield Green, with very good Lady

Downe's; third, Mr. W. Peters, gardener to H. P. Sturgis, Esq., Leatherhead, with Gros Maroc. Four more entries. Muscat of Alexandria, three bunches: First, Mr. W. Taylor, Forest Hill, with very good, well-coloured bunches; second, Mr. W. Mitchell; third, Mr. Goodacre. There were five more entries.

Any other white variety, three bunches: First, Mr. W. Taylor, Forest Hill, with Chasselas Napoleon very well shown; second, Mr. J. Brown, gardener to Joseph Drakes, Esq., Market Rasen, with Golden Queen; third, Mr. G. Beech, gardener to John Barker, Esq., Bishop's Stortford, with Golden Queen also.

Collection of hardy fruits (thirty dishes), distinct, grown in the open: First, Mr. W. H. Bacon, gardener to Sir Marcus Samuel, Bart., Maidstone, who showed excellent Apples Blenheim Pippin, Peasgood's Nonsuch, Mère de Ménéage, and Warner's King; Pears Triomphe de Vienne, General Todtleben, and Pitmaston Duchess, as well as good Peach Sea Eagle, Plums, Damsons, Strawberry St. Joseph, Brown Turkey Figs, &c.; second, Mr. E. Coleman, gardener to T. L. Boyd, Esq., Tonbridge; his Apples and Pears were very fine.

DIVISION II.—NURSERYMEN AND MARKET GROWERS ONLY.

For an exhibit of fruit grown out of doors, to fill 24 feet run of 6 feet tabling, Messrs. George Bunyard and Co., Maidstone, were first. Many very fine dishes were comprised in their collection, e.g., Apples King of the Pippins, Bismarck, Hereford Crimson Queening, Cox's Pomeña, Calville Rouge, Precocée, Wealthy (all finely coloured), Golden Spire, Royal Jubilee, and Lord Derby; Pears Conference, Marguerite Marillat, Triomphe de Vienne, Beurre Jan Van Geert, Pitmaston Duchess, and others. Messrs. Cannell and Sons, Swanley, Kent, were second. Their exhibit contained many excellent dishes, the Apples being finely coloured. Cellini, Lord Derby, Emperor Alexander, Peasgood's Nonsuch, Gascoyne's Scarlet Seedling, and others were beautiful fruits. Messrs. W. Poupart and Sons, market growers, Twickenham, were third; they showed fruits in boxes and baskets. There were several other entries in this class, all the exhibits being good.

Fruit grown entirely out of doors, to cover 16 feet run of 6 feet tabling. The first prize in this competition was won by Mr. J. Basham, Bardsley, Mon. The finest Apples and Pears were boldly arranged in baskets, while around the margin were dishes of miscellaneous fruits. Such Apples as Jolly Miller, Tamplin (local), Gascoyne's Scarlet Seedling, Crispin Queening, and Gravenstein were splendidly coloured. Ecklinville Seedling, Peasgood's Nonsuch, The Queen, and others were very finely shown. Among Pears Souvenir du Congrès was splendid. The second prize was won by Mr. G. Mount, Canterbury, whose exhibit also contained many excellent dishes. Apples Allington Pippin, Lane's Prince Albert, Tower of Glamis, Peasgood's Nonsuch, Pears Marguerite Marillat and Pitmaston Duchess were among the best. Messrs. Laxton Bros., Bedford, were third. The Apples in this collection were also very good. There were several other entries in this class, and the exhibits were conspicuous features in the hall.

For an exhibit of orchard house fruit and trees, to cover 24 feet run of 6 feet tabling, Messrs. George Bunyard and Co., Maidstone, were first. This exhibit consisted of some forty fruit trees in pots, and dishes and baskets of fruits arranged between them. Of the fruit trees Apple Gascoyne's Scarlet Seedling carried good crops of splendidly coloured fruits, Emperor Alexander was very good, so were Lord Burghley and Peasgood's Nonsuch, while among the Pears Beurre Bosc, Doyenne du Comice, Beurre Fouquieray, and Vicar of Winkfield were very good. The dishes of fruits of Peasgood's Nonsuch were wonderfully fine, and those of Gascoyne's Scarlet Seedling were beautifully coloured. Two enormous fruits of Pear Marguerite Marillat were shown. Other good dishes were Pears Beurre Alexandre Lucas, Winter Windsor, Pitmaston Duchess, Duchesse d'Angoulême, Marie Benoist, General Todtleben, and Apples Allington Pippin, Royal Jubilee, Mother, Lane's Prince Albert, Twenty Ounce, and Washington. Messrs. T. Eivers and Son, Sawbridgeworth, were second. They exhibited of pot fruit trees Plum Rivers, Late Orange, bearing splendid crops of fruit, Pears Magnate and Conference, Apple Emperor Alexander, and Gascoyne's Scarlet Seedling, Peach Salway, and Grapes Directeur Tisserand and Golden Queen, all bearing good crops. There were some splendid fruits among the dishes of Apples and Pears; for instance, the fruits of Cox's Orange Pippin, Peasgood's Nonsuch, and Ribston Pippin were most beautifully coloured, perfect examples of these varieties. Emperor Alexander was almost equally good, and others worthy of special note were Apples Thomas Rivers, The Queen, Lady Sudeley, and Washington, Pears Souvenir du Congrès, Magnate, Princess, Durondeau, and Parrot, Plum Golden Transparent, and various Grapes.

DIVISION III.—GARDENERS AND AMATEURS ONLY.

Twenty-four Apples, distinct: First, Mr. C. Crane, gardener to Mrs. Alexander, Maidstone, with some very good dishes; second, Mr. W. Lewis, gardener to R. H. B. M. rsham, Esq., Maidstone; third, Mr. C. J. Salter, gardener to Mr. Haywood, Reigate. Some splendid fruits were shown in this class, which was well contested.

Apples, eighteen dishes, distinct: First, Mr. J. Dawes, gardener to Lord Biddulph, Ledbury. Many of the fruits were beautifully coloured; for instance, Tyler's Kernel, Gascoyne's Scarlet, Worcester Pearmain, and The Queen. Peasgood's Nonsuch, Beauty of Kent, and Warner's King were very fine; second, Mr. C. Earl, gardener to O. E. Goldsmid, Esq., Tonbridge; third, Mr. J. Challis, gardener to the Earl of Pembroke, Salisbury.

Apples, twelve dishes distinct: First, Mr. W. Wallace, gardener to Hugh C. Smith, Esq., Roehampton. King of the Pippins was a beautiful dish, and Ribston Pippin, Stirling Castle, and Annie Elizabeth were very good; second, Mr. J. Vert, gardener to Lord Howard de Walden, Saffron Walden. Peasgood's Nonsuch was finely coloured, and Warner's King unusually good.

Cooking Apples, six dishes, distinct: First, Mr. C. Crane, gardener to Mrs. Alexander, Maidstone, with very good fruits of Emperor Alexander, Warner's King, Belle du Bois, and

others; second, Mr. J. Smith, gardener to Earl de Grey, Kingston.

PEARS.

Dessert Pears, eighteen dishes, distinct: In this class there were only two entries, the first prize going to Sir Marcus Samuel, Bart., Maidstone (gardener, Mr. W. H. Bacon), who had fruit of remarkable size, including Triomphe de Vienne, Durondeau, Doyenne Bussch, Beurre Superfin, Pitmaston Duchess, and others, all of equal quality. The second prize was won by Major Powell Cotton, Birchington (gardener, Mr. J. Cornford).

Dessert Pears, twelve dishes, distinct: There were four entries. The first prize was gained by the Rev. T. McMurdie, Woburn Park (gardener, Mr. A. Bastie), who had fine examples of Souvenir du Congrès, Durondeau, Marie Louise, and Duchesse d'Angoulême; the second prize went to Mrs. Alexander, Maidstone (gardener, Mr. C. Crane); and the third to the Earl of Pembroke, Salisbury (gardener, Mr. T. Challis).

Dessert Pears, nine dishes, distinct: There were four entries, the first prize being won by Lord Biddulph, Ledbury (gardener, Mr. J. Dawes), his Pitmaston Duchess, Magnate, and Marie Louise being very fine; the second prize was gained by F. A. Bevan, Esq., Trent Park (gardener, Mr. H. Parr).

Dessert Pears, six dishes, distinct: There were eight entries in this class. The first prize was gained by C. A. Morris Field, Esq., Sevenoaks (gardener, Mr. R. Edwards), with very fine fruits; the second prize went to the Duke of Portland, Welbeck (gardener, Mr. J. Roberts).

Stewing Pears, three dishes, distinct: The first prize was gained by Major Powell Cotton, Birchington (gardener, Mr. J. Cornford), with fine examples of Catillac, General Todtleben, and Grosse Calebasse; second prize went to N. Nichaelis, Esq., Tandridge Court (gardener, Mr. J. D. Simmonds), who had very fine Uvedale's St. Germain.

Peaches grown entirely out of doors, three dishes, distinct: There were twelve exhibits in this class, all being good. The first prize was gained by the Earl of Harrington (gardener, Mr. J. H. Goodacre), with fine examples of Golden Eagle, Harrington, and Exquisite; second prize was awarded to C. R. W. Adeane, Esq., Cambridge (gardener, Mr. R. Alderman).

Peaches, one dish of any one variety from the open: There were twelve entries in this class, the first prize going to Mrs. Alexander of Maidstone for a fine dish of Sea Eagle; second prize went to J. J. Morrish, Esq., Oxshott (gardener, Mr. C. W. Miles), for Late Admirable.

Nectarines grown out of doors, three dishes, distinct: There was only one entry, but no award was made, the fruits not being sound.

Nectarines, one dish of any one sort from the open: In this class there were seven exhibitors, all showing well. The first prize went to Lord Biddulph, Ledbury (gardener, Mr. J. Dawes), for the fine fruits of Humboldt; second prize to R. Beddingfield, Esq., Roehampton (gardener, Mr. J. Sparks), with the same variety.

Plums grown under glass, six dishes, distinct: There were two entries only, the first prize being gained by Lord Howard de Walden, Saffron Walden (gardener, Mr. J. Vert), Late Orange, Decaisne, and Primate being very fine; the second prize went to M. R. Smith, Esq., Hayes (gardener, Mr. C. Blick).

Plums (two dessert and four cooking): In this class there were nine entries. The first prize was won by Lord Howard de Walden (gardener, Mr. J. Vert), who had Coe's Violet, Coe's Golden Drop, Fond's Seedling, Grand Duke, Primate, and Monarch; the second prize went to the Earl of Stair, Dalkeith (gardener, Mr. W. Smith), his Jefferson and Goliath were very fine.

Three dishes of Gage Plums, distinct: There were five entries, the Earl of Pembroke (gardener, Mr. T. Challis) being first with fine examples of Transparent Gage, Rivers' Golden Gage, and Oullin's Golden Gage; the second prize went to J. E. Fortescue, Esq., Droghda, Maidenhead (gardener, Mr. C. Page), whose Bryanston Gage was very fine.

One dish of Coe's Golden Drop. Here there were fifteen entries. The first prize was won by the Marquis of Northampton, Castle Ashby (gardener, Mr. A. R. Searle), with very fine fruits; the second prize went to Lord Howard de Walden.

One dish of any other dessert Plum: In this class there were ten entries, the first prize going to J. K. D. Wingfield Digby, Esq., M.P., Sherborne Castle (gardener, Mr. T. Taiton), who had very fine examples of Reine Claude de Bayay; the second prize was won by J. Liddell, Esq., Newbury (gardener, Mr. R. Lye), with good fruits of Jefferson.

One dish of cooking Plums, any variety: The first prize was gained by F. N. Thomas, Esq., Wannock, Polegate, with White Magnum Bonum, which were of good quality; the second prize went to Lord Howard de Walden for splendid fruit of Monarch. There were twenty entries in this class.

Damsons, three dishes, distinct: There were only two entries. The first prize was gained by G. J. Gribble, Esq., Biggleswade (gardener, Mr. A. Carlisle), with Blue Prolific, Bradley's King, and Fairleigh Prolific; the second prize went to T. Clinch, Esq., Sittingbourne.

Bullace, one dish of any variety: Here again there were only two entries, the first prize going to T. Clinch, Esq., and the second prize to Hugh C. Smith, Esq., Roehampton (gardener, Mr. W. Wallace).

Morello Cherries, fifty fruits: In this class there were five entries, the first prize being won by H. F. Walker, Esq., Balcombe (gardener, Mr. J. Coles), who had remarkably fine fruits; the second prize went to J. E. Fortescue, Esq., Maidenhead (gardener, Mr. C. Page).

Grapes grown out of doors: Hugh Smith, Esq., Roehampton, was the only exhibitor in this class, and was awarded second prize for some unripe bunches.

DIVISION IV.—SPECIAL DISTRICT COUNTY PRIZES.

Gardeners and Amateurs only.

Each of these classes is sub-divided, prizes being offered for six dishes, distinct, of Apples, and six dishes, distinct, of Pears in each county or collection of counties.

W. Stowers, Esq., Sittingbourne, was first for Pears with excellent fruits of Conference, Marguerite Marillat, finely coloured; Doyenne Boussoch, King Edward, and Pitmaston Duchess. The same exhibitor took the leading place for Apples Rival, Cox's Orange Pippin, The Queen, and Peasgood's Nonsuch being fine and well coloured. The second prize was won by T. L. Boyd, Esq., Tonbridge (gardener, Mr. E. Coleman), whose best Apples were Fearn's Pippin, Cox's Orange Pippin, Bismarck, and The Queen; and the best Pears Doyenne du Comice and Triomphe de Vienne.

Open to Growers in Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall.

For Apples: B. H. Hill, Esq., Crediton (gardener, Mr. Lock), was first with grand fruits of Peasgood's Nonsuch, Emperor, and Mere de Ménage; Cox's Orange Pippin was also good; second, J. D. Wingfield Digby, Esq., M.P., Sherborne Castle (gardener, Mr. Turton), with fine specimens of Annie Elizabeth and Peasgood's Nonsuch. For Pears: F. W. Thomas, Esq., Waincock, came first, his Marguerite Marillat and Triomphe de Vienne being very handsomely coloured; Pitmaston Duchess was also very good; second, J. D. Wingfield Digby, Esq., Sherborne Castle, with a very even lot, in which Durondeau, Doyenne Boussoch, and Beurre Superfin were excellent. There was close competition in these classes.

Open only to Growers in Wilts, Gloucester, Oxford, Bucks, Beds, Herts, and Middlesex.

For Apples: A. G. Wright, Esq., Newent (gardener, Mr. Davies), was first, his Worcester Pearmain, Peasgood's Nonsuch, The Queen, and Gascoyne's Scarlet being very fine; second, G. J. Gribble, Esq., Biggleswade (gardener, Mr. A. Carlisle), Emperor Alexander and Peasgood being exceptionally good. For Pears: Mrs. H. St. V. Ames, Westbury-on-Trym (gardener, Mr. Banister), was first, Doyenne Boussoch and Beurre Hardy being the finest specimens; second, G. J. Gribble, Esq., whose excellent fruits were all unnamed.

Open only to Growers in Essex, Suffolk, Norfolk, Cambridge, Hants, and Rutland.

For Apples: R. M. Coutail, Esq., Colne Elgiant (gardener, Mr. C. Taylor), was first, with brilliantly coloured fruits of Bismarck, Gascoyne's Scarlet, Allington Pippin, and Cox's Orange Pippin; second, Colonel G. B. Archer-Houlton, Bishop's Stortford, who had a notable dish of Chas. Ross. For Pears: Colonel the Hon. C. Harbord, Norwich (gardener, Mr. W. Allan), was first, Marguerite Marillat, Doyenne du Comice, and Doyenne Boussoch being his best dishes; second, Colonel Archer-Houlton.

Open to Growers in Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffs, Shropshire, and Cheshire.

For Apples: J. Lea, Esq., High Bebbington, was first, Cox's Orange Pippin, Peasgood's Nonsuch, and Gascoyne's Scarlet being the best; second, the Duke of Rutland, Belvoir Castle (gardener, Mr. W. Divers), whose fruits were of finer colour altogether. Duchess's Favourite, Ribston Pippin, Peasgood's Nonsuch, The Queen, and Gascoyne's Scarlet were admirable examples. For Pears the Duke of Bedford took first place with excellent dishes of Renre Superfin, Durondeau, and Souv. du Congrès; second, Major Hubbert, Rugby, with fine fruits of Triomphe de Vienne, Williams' Bon Chrétien, and Durondeau. There was very keen competition in these classes.

Open to Growers in Worcester, Hereford, Monmouth, Glamorgan, Carmarthen, and Pembroke.

For Apples: First, H. C. Moffatt, Esq., Ross (gardener, Mr. Spencer), his best dishes being Tyler's Kernel, Peasgood's Nonsuch, and Winter Pearmain; second, R. N. Whiting, Esq., Hereford, with fine Wealthy, Cox's Orange Pippin, and splendid Peasgood's Nonsuch. For Pears: First, H. C. Moffatt, Esq., Triomphe de Vienne, Doyenne de Merode, and Souvenir du Congrès being the best; second, the Dowager Lady Hindlip, Droitwich (gardener, Mr. C. Crooks), with Louise Bonne of Jersey, Doyenne du Comice, and Pitmaston Duchess finely shown.

Open to Growers in the other Counties of Wales.

For Apples: First, Colonel Cornwallis West, Ruthin (gardener, Mr. H. Forder), who had good dishes of Alfriston, Peasgood's Nonsuch, Ribston Pippin, and Cox's Orange Pippin. The same exhibitor was first for Pears, Clapp's Favourite, and Beurre Hardy being the best.

Open only to Growers in the Six Northern Counties of England and in the Isle of Man.

For Apples: First, the Earl of Lathom, Ormskirk (gardener, Mr. Ashton), who had fine dishes of Tyler's Kernel, Warner's King, and Peasgood's Nonsuch. The first prize for Pears also went to this exhibitor, who staged five dishes of Williams' Bon Chrétien, Souvenir du Congrès, Margaret Marillat, &c.

Open only to Growers in Scotland.

For Apples: First, the Duke of Richmond and Gordon, Gordon Castle, who had Peasgood's Nonsuch, Newton Wonder, Worcester Pearmain, and Allington Pippin, all in fine condition; second, the Earl of Galloway, Gariestown, whose best dishes were James Grieve, The Queen, Peasgood's Nonsuch, and Worcester Pearmain. For Pears the positions of the two exhibitors were reversed, the Earl of Galloway coming first with Marguerite Marillat, Gratioli of Jersey, and Williams' Bon Chrétien, while the Duke of Richmond and Gordon had Pitmaston Duchess, Marie Louise, Beurre d'Amanlis, and others.

Open only to Growers in Ireland.

For Apples: First, Viscount Duncannon, Deborrough, Piltown (gardener, Mr. J. G. Weston), whose best dishes were The Queen, Bismarck, Worcester Pearmain, and Colouel Vaughan's Pippin.

DIVISION V.—SINGLE DISHES OF FRUIT GROWN IN THE OPEN AIR.

Gardeners and Amateurs only.

CHOICE DESSERT APPLES.

Allington Pippin: First, W. Stowers, Esq., Sittingbourne, with a very handsome dish; second, F. W. Thomas, Esq.,

Polegate. There were some two dozen competitors in this class.

American Mother: First, H. C. Moffatt, Esq., Ross (gardener, Mr. Spencer); second, W. R. Page, Esq., Clacton-on-Sea, both showing well in a large competition.

Glenheim Orange (small, highly-coloured fruits to pass through a 3-inch ring): First, R. J. Lambert, Esq., Oxshott (gardener, Mr. Reid); second, J. Colman, Esq., Garton Park (gardener, Mr. W. Bound). Very handsome fruits in each case. Some twenty-eight dishes were staged.

Chas. Ross: First, Mr. G. Pyne, Topham; second, Mr. W. Stowers, Sittingbourne. The ten dishes shown were all good, the leading ones splendid.

Cox's Orange Pippin: First, Lord Poltimore, Exeter (gardener, Mr. I. H. Slade), with a very fine dish; second, Mr. F. B. Parfitt, Caversham. Some three dozen dishes were staged.

Egremont Russet: First, Walpole Greenwell, Esq., Marden Park; second, J. L. Boyd, Esq., Tonbridge.

James Grieve: First, Colonel Archer-Houlton, Bishop's Stortford; second, Mr. R. M. Whiting, Crediton.

King of the Pippins: First, Mr. Stowers, Sittingbourne; second, J. L. Newland, Esq., Byfleet. Many good dishes were staged.

Lady Sudeley: First, R. D. Wingfield Digby, Esq., with grandly coloured fruits; second, G. J. Gribble, Esq., Biggleswade.

Margil: First, A. W. Wright, Esq., Newent; second, G. J. Gribble, Esq.

Ribston Pippin: First, Sir Oswald Mosley, Bart., Burton-on-Trent (gardener, Mr. G. Woodgate); second, Walpole Greenwell, Esq., Marden Park. Over thirty dishes were staged of this variety.

Worcester Pearmain: First, J. B. Fortescue, Esq., Maidenhead (gardener, Mr. Page); second, G. J. Gribble, Esq.

Any other variety not named above: In this class the first prize went to Cornish Aromatic, shown by the Hon. Justice Swinfen Eady, Weybridge; the second prize went to Mr. W. Stowers, Sittingbourne, who had Rival, a finely coloured and hand-ome fruit; third, also to Rival, from Colonel Archer-Houlton.

Bismarck: First, J. R. D. Wingfield Digby, Esq., Sherborne Castle; second, E. W. Caddick, Esq., Ross, Hereford.

Glenheim Orange: First, the Hon. Justice Swinfen Eady, Weybridge (gardener, Mr. J. Lock), with grand fruits; second, H. C. Smith, Esq., Rushampton. Over twenty dishes were staged.

Brantley's Seedling: First, Colonel Archer-Houlton; second, E. W. Caddick, Esq. Many fine dishes were staged in this class.

Eckluiville Seedling: First, Mr. R. M. Whiting, Hereford; second, J. Colman, Esq., Reigate.

Gascoyne's Scarlet: First, Mr. F. W. Stowers, Polegate; second, Mr. W. Stowers, Sittingbourne.

Golden Noble: First, A. W. G. Wright, Esq., Newent; second, M. Michaels, Esq., Tandridge Court.

Grenadier: First, J. B. Fortescue, Esq., Maidenhead.

Lane's Prince Albert: First, Colonel Archer-Houlton, with a superb lot of fruits.

Lord Derby: First, Mr. W. Stowers, Sittingbourne.

Mère de Ménage: Here again Mr. Stowers took the lead.

Newton Wonder: First, Earl of Londeshorough, Market Weighton (gardener, Mr. J. C. McPherson), with perfect examples; second, the Duke of Rutland; third, Colonel Harbord, Norwich. This class was open to exhibitors in Cardigan, Radnor, Shropshire, Stafford, Warwick, Bedford, Northampton, Cambs, Essex, or counties further north. (Prizes given by Messrs. Pearson and Sons, Loughdam, Notts.)

Newton Wonder (open to exhibitors living south of the before-named counties): First, Mr. W. Stowers, Sittingbourne; second, Earl of Pembroke, Salisbury. The fruit in both these classes was of excellent quality and of a high standard throughout. (Prizes by Messrs. Pearson and Sons.)

Peasgood's Nonsuch: First, Hon. W. Lowther, Wickham Market (gardener, Mr. A. Andrews); second, C. E. Hambury, Esq., Ware, both having superb dishes. Two dozen dishes were staged of this noble fruit.

Potts' Seedling: First, J. R. D. Wingfield Digby, Esq., Stirling Castle; first, Colonel Archer-Houlton.

Waltham Abbey Seedling: First, E. W. Caddick, Esq., Warner's King; first, N. R. Page, Esq., Clacton-on-Sea.

Any other variety: First, Colonel Waide, Maidstone, with a fine lot of Rambour Papaleon.

CHOICE DESSERT PEARS.

Beurre Hardy: First, Mrs. H. St. V. Ames, Westbury-on-Trym.

Beurre Superfin: First, J. R. D. Wingfield Digby, Esq.

Comte de Lamy: First, Hon. C. Harbord.

Doyenne du Comice: First, Hon. C. Harbord.

Durondeau: First, Colonel Warde, M.P.

Emile d'Heyst: First, J. R. D. Wingfield Digby, Esq.

(gardener, Mr. Turton), who had a fine dish.

Fondante d'Automne: First, H. C. Moffatt, Esq., Hereford.

Louise Bonne of Jersey: First, E. A. Lee, Esq., Liphook, whose dish was excellent.

Marguerite Marillat: First, Mr. W. Stowers, Sittingbourne, with a dish of perfect fruit.

Marie Louise: First, Colonel the Hon. C. Harbord, Norwich.

Pitmaston Duchess: First, J. B. Fortescue, Esq., Maidenhead. There were many admirable dishes.

Souvenir du Congrès: First, the Rev. J. McMurdie, Weybridge.

Thomson's: First, J. R. D. Wingfield Digby, Esq.

Triomphe de Vienne: First, H. Boyd, Esq., Tonbridge.

Williams' Bon Chrétien: First, Colonel G. B. Archer-Houlton with grand fruits.

Any other variety not named above: First, Mr. W. Stowers, with Doyenne Boussoch; second, J. R. D. Wingfield Digby, Esq., with Mme. Treve.

AWARDS OF MERIT.

Apple Werder's Golden Reinette.—A handsome fruit, a cross between Cox's Orange Pippin and Allington Pippin. It ripens

in October and is very prolific. From Messrs. J. Veitch and Sons, Chelsea.

Apple Hector Macdonald.—A very handsome Apple, reminding one of Peasgood's Nonsuch. The fruits are striped with red. From Mr. C. Ross, gardener to Colonel Archer-Houlton, Welford Park, Newbury.

Apple King's Acre Bountiful.—A yellow fruit, heavy cropper, and with a pleasantly brisk flavour. From the King's Acre Nursery Company, Hereford.

Pear S. T. Wright.—An early Pear of good flavour, a cross between Beurre Bachelier and Williams' Bon Chrétien. (Veitch).

CROYDON HORTICULTURAL SOCIETY.

BEFORE the members of the above society recently a lecture on "Fruit as a Necessary Food" was delivered by Mr. H. Cannell, V.M.H., Swanley. For the last ten years Mr. Cannell's diet has been strictly vegetarian, he said, and he was happy to say that although just before his commencement on this diet he was feeling very much an old man, yet now he felt more active, enjoyed better health, and looked at his future with brighter views in every way. Statistics, he said, all pointed to the decadence of our race. Men and women did not live as long, and while life lasted did not enjoy such good, robust health as in generations gone by. Why? Because we were deviating considerably from a natural existence. Men sometimes abstained from fruit for months together, and in so doing brought upon themselves ailments which would not exist if greater thought was bestowed on what they should eat and drink. In fruit they had enough nourishment to keep the body in proper working order, and not only this, but it created the appetite and provided everything to build up a strong constitution. The liking for fruit was a natural taste. He also emphasised its economy. At a nominal cost meals could be provided for families, whereas now the cost of living was one of the most serious items the working man had to face. With the cheaper sustenance obtained in fruit and vegetable food healthier bodies and healthier minds would naturally follow.

Mr. Robert Cannell, a son of the lecturer, explained an easy method of preserving fruit, and handed round samples of this and wholemeal bread, which were very palatable and appreciated by all present.

A hearty vote of thanks was unanimously accorded Mr. Cannell for his address, and also for the exhibit of fruit from his nurseries. Thanks were also conveyed to Mr. W. Lintott, Marden Park Gardens, for an exhibit of Begonia Marie Bouchett.

CLEPINGTON GARDENS ASSOCIATION, DUNDEE.

THE twenty-fourth annual report of the committee, submitted at the annual meeting of this association held on the 22nd ult., was of a generally satisfactory character. Owing to the absence of extraordinary repairs, the funds showed a gain of £6 13s. 4d. on the year, a considerable part of the improvement in the funds being due to the vigilance of their treasurer, who had paid great attention to his duties. The annual competition in July had been a successful one, while the gardens had been generally well kept during the year. The report was adopted, and the following officer-bearers elected: President, Mr. W. R. Ogilvie; treasurer, Mr. William Gall; secretary, Mr. A. H. Rea; committee, Messrs. J. Allan, D. Craig, J. Davidson, J. Edwards, W. Langlands, and D. Middleton.

BROUGHTY FERRY HORTICULTURAL ASSOCIATION.

THE first of the series of monthly evening meetings arranged for the winter by this association was held recently. A good feature of the meeting was the excellent little exhibition and competition, a number of cut flowers and other horticultural produce of much merit being shown. In the competition for vegetables the first prize was awarded to Mr. Joseph Dick, Heathbank Gardens, Barnhill, the second being won by Mr. William Ross, The Bachties Gardens. The paper for the evening was given by Mr. James Reid, The Gardens, Dudhope House, Dundee, his subject being "Herbaceous Plants." It was a most interesting one, and was followed with close attention, as was shown by the discussion which followed. Mr. James Slater presided.

THE KINGSTON GARDENERS' ASSOCIATION.

THE first of a winter course of lectures to be given fortnightly to the members of this newly formed society was given on Friday, the 30th ult., by the president, Mr. E. H. Jenkins, F.R.H.S., his subject being "Daffodils." In this category every member of the great Narcissi family was included. Besides a number of excellent illustrations, the lecturer was aided by a quantity of representative bulbs kindly supplied by Messrs. Barr and Son. Dealing with the history of the family, both traditional and actual, the lecturer led on to classification, the sample bulbs much helping to that aim. Their culture in gardens, with advice as to soils, suitable varieties, and methods of planting followed. Mr. Jenkins thought the less lifting practised the better, and quoted cases to show how deep and strong long-planted bulbs would become. Forcing was also concisely dealt with, and excellent advice given. A cordial vote of thanks closed the proceedings.

REDHILL AND REIGATE GARDENERS' SOCIETY.

THE fortnightly meeting was held in St. Matthew's School-room on Tuesday, the 27th ult., the lecturer being Mr. A. Trowers, who read a paper on "Spring Gardening." Over 100 members were present. The lecturer dealt very ably with the subject, and clearly showed the great pleasure to be obtained by naturalising bulbs in grass. Many pretty effects could be obtained by making a judicious selection of bulbs. This, the lecturer contended, would give a maximum of satisfaction for a minimum of trouble and expense. The lecturer strongly advised a careful selection of good bulbs. The society's certificate were awarded to Messrs. Mead, Coomber, and Peters, all of whom showed meritorious exhibits.

THE GARDEN

No. 1717.—Vol. LXVI.

[OCTOBER 15, 1904.]

THE NATIONAL POTATO SOCIETY'S EXHIBITION.

SOME remarkable facts were brought to notice on the occasion of the first exhibition of the newly-formed National Potato Society, by the chairman, Mr. A. D. Hall, M.A., who is director of the Rothamsted Experimental Station. Mr. Hall said that no less than 570,000 acres of land were devoted to Potato culture in the United Kingdom. Estimating each acre to yield five tons, he reckoned the annual value of our Potato crop to be something like £10,000,000. If the many acres of miscellaneous crops, as those grown by cottagers, allotment holders, &c., were taken into account, then £20,000,000 would be a more correct estimate of the total value of Potatoes grown in this country. Mr. Hall put the value of an acre of wheat at £12, while an acre of the best Potatoes he considered to be worth £35.

The British farmer must grow crops of a high monetary value in order successfully to cope with the heavy railway rates, working expenses, and other difficulties under which he labours, and it seems that he might do much worse than turn his attention to Potato culture. As Mr. Hall pointed out, a good deal has been said lately about the reforestation of waste land in this country; but, whereas in that case the planter has to wait years before he can expect any result from his labour and outlay (3 per cent. at the end of thirty years was given as an approximate return to be expected), the Potato grower gets quick returns and also higher prices for his produce than even the farmer does for his corn crops. It is well known that any crop grown so intensively as the Potato now is in this country, is very liable to disease, and readily succumbs to its ravages if steps are not taken either to prevent disease spreading or to stamp it out. A good deal of ignorance also prevails as to which varieties are really the best. For some time growers have put on the market varieties introduced by themselves, with the result that there are now dozens of sorts all described as of the highest quality—a state of affairs that is puzzling and also annoying to the amateur or small grower who wants to get the best Potatoes.

It is to lend a helping hand to the British farmer and the Potato grower that the National Potato Society was formed, and if the great exhibition of tubers and the enthusiastic gathering of growers from all parts of the

kingdom at the Crystal Palace on the 11th and 12th inst. may be taken to indicate the condition of this, the youngest of horticultural societies, then it is evident that it is very flourishing indeed. At the luncheon given to the judges and others one grower remarked that the Potato Society had done more towards bringing about the co-operation of the British farmers than all the writings and preachings of would-be benefactors, who urged the farmers to co-operate, but never put before them any practical suggestion.

This society has already done valuable work in establishing trial stations in different parts of the country for the purpose of testing new varieties of Potatoes. It is hoped that raisers of new varieties will co-operate with the society in this all-important work, and send samples of their introductions, so that they may be grown side by side, and thus compared with others. On behalf of his firm, Mr. Arthur Sutton said they would gladly do this, and we have no doubt that others will follow the example. The bane of synonyms is prevalent among Potatoes as well as among other plants, and, as Mr. Sutton pointed out, the only way in which to determine correctly the names of varieties is to grow them together under the same conditions. It is impossible to identify a variety solely by the tubers. The society is also doing good work in circulating information about diseases which attack the Potato, and the best preventives and remedies—matters of the greatest importance to growers. Although only formed early this year, the Potato Society already has a membership of nearly 2,000, thanks chiefly to the energy of the honorary secretary, Mr. Walter P. Wright and his co-workers, who are to be congratulated upon so successful an issue to their first year's work. It may be of interest to mention that Mr. Robert Fenn, who is eighty-eight years of age, and was the first to cross-fertilise the flowers of the Potato with a view to obtaining new varieties, was present at the exhibition.

None could fail to notice that nearly all the prizes in the competitive classes went to Scotland or the north of England. There is no doubt that the coolness and moisture that prevail in Scotland to a greater degree than south of the Tweed are peculiarly suited to successful Potato culture. Even the non-competitive exhibits, which formed the most important feature of the show, were chiefly from Scotland. A noteworthy exception was

the splendid exhibit from Messrs. Sutton and Sons, Reading, which won the Llewelyn Cup given for the best exhibit of Potatoes in the show.

SUGGESTIONS FOR THE GROUPING OF BULBS.

THERE is one most important question which exercises our minds most severely at planting-time, and which not even the most experienced gardener can summarily dismiss as unworthy of consideration, and that is, "How will it all look when in flower?" We try to think it over, and ask ourselves more questions. "Have we got them too close together or too far apart?" "Ought not that tall-growing *Rudbeckia* to be set back a bit?" "Won't that *Spiraea* spread too much and be a nuisance? Why not take it right out and put in something less aggressive, and add another plant or two to the group of *Irises* instead?"

Perhaps we do shift a few plants; more probably we leave the border or the rockery bed as it is. Everything looks so nice and clean and tidy, and the labels are neatness itself, if perhaps a bit "graveyardy." We can always move a thing or two later on if we have made any bad mistakes. And in the end, when the plants have responded to their good treatment and have put on their best garden-party colours, we find there is not much to find fault with after all, and we are not ashamed to show our new bit of planting to any of our visitors, however formidable and learned in horticulture they may be.

We may, indeed, afterwards do a little bit of shifting and lifting, of addition and subtraction, on the quiet, to make the thing *quite* perfect, and small blame to us, for it is indeed but seldom that the first arrangement of a new or a renovated scheme of planting is so absolutely successful that we can afford to leave it severely alone, and bring our friends confidently to it and say, "There!"

As with shrubs and plants, so it is with bulbs, the only difference perhaps being that it is a still more difficult job to arrange them properly and to our satisfaction at the first attempt. This leads me on to the title of my notes (or rather suggestions, for they can be no more, on such a subject), the successful grouping and arrangement of bulbs at planting time, especially in cases where we are about to employ bulbs only, in the given space. To add bulbs to an existing border or rockery already more or less occupied is to my mind a far easier matter, though even this requires much care and thought.

Most of us know and have probably decided what bulbs we shall want, and how many, approximately, of each sort, and we probably obtain them in due course. If we are only going to put in *Narcissi*, *Snowdrops*, or *Tulips* in clumps along the border, the thing is

simplicity itself, and, in addition, an odd corner can generally be found for a small lot of any other bulbs, or specially reserved nooks and sunny spots for our rarities. The trouble begins when we wish to launch out into a bulb "corner" in the grass, or a flowery spring "cascade" on the rockery. Then the "clump" system fails to please, and we must go about our work with far greater care and circumspection. Of course, there must be clumps, and many of them, but not of the circular "dozen-bulb" type as applied to the formal border. They must be carefully set out in outline before beginning to plant, with sticks or labels easy to see, the latter being shifted and rearranged into the most natural and pleasing irregularity, in a laudable endeavour to imitate Nature. For Nature abhors a "clump," as she does a "vacuum"; one has only to look at a bit of her planting, whether of trees or shrubs or flowers, in their wild state in the woods and meadows and on the moorland, to be made aware of that fact.

We must try and follow her style then, whether it be with a barrow-load of a thousand Narcissi, or with a tiny little packet of choice Scillas, and the result will be all the more pleasing the more closely we study and imitate her in her graceful carelessness. Let us now take the case of a portion of grassland on the lawn, or in the wild garden, which we propose to plant with bulbs only, assuming for the sake of example that there are no trees or shrubs already there which might influence and assist us in our ideas. We must arrange our bulbs somewhat in the following manner: First a big irregular mass in a chosen spot, lengthening itself out in one or more directions into points and promontories of varying size and shape; then, say, a single bulb; then a group of five; another single; a mass again; a pair; yet another huge gathering, more tightly packed for a change; and so on, until enough space has been allotted to the one particular kind of bulb, or until the basket is empty. Each mass, or constellation of stars, should seem as it were to be expanding and striving to unite with its bulky neighbours, sending out its starry messengers towards them, connecting links in the miniature flowery universe, while there should at the same time be visible a tendency of the whole system to increase and radiate outwards in irregular projecting points and broken lines of varying length and substance. This I am afraid will sound a trifle far-fetched; I hope it is not very much so. At any rate, it conveys my meaning with tolerable clearness, so I pray it may be excused.

S. G. REID.

(To be continued.)

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

SEEDLING MICHAELMAS DAISIES.

Mr. Archer-Hind sends a charming series of Michaelmas Daisies from his own raising, the

colours blue, rose-purple, white, and pink, but one of the most precious of all is called *Coombe-fishacre White*, a flower of rare purity. Mr. Archer-Hind says: "The original *Coombe-fishacre* prevails in most. I find it the best for crossing."

We hope this ardent gardener will long be spared to continue his interesting work.

AKEBIA QUINATA FRUIT.

We receive from Mr. Pandeli Ralli, Alderbrook, near Guildford, the curious large grey pod of fruit of *Akebia quinata*. It is interesting to receive it from this district, where fruiting is uncommon.

GLOXINIA MACULATA.

Mr. J. Mayne, Bicton, sends flowers of this interesting plant with the following note: "An old occupant of our glass structures, but seldom seen outside a botanical garden, nevertheless worthy of a place in a mixed collection of stove plants. It is quite distinct from the ordinary *Gloxinia* of to-day, in fact it is more like the *Gesnera* in growth, sending up many sucker-like shoots, varying in height from 12 inches to 20 inches. A well-grown specimen often carries eighteen individual flowers on a spike, which emanate singly from the axil of the leaf on either side, purple in colour, and of the shape of the old form of drooping or pendulous *Gloxinia*. Coming into flower in the early autumn adds value to the plant, and forms a succession to the *Achimenes*. After passing out of flower it should receive similar treatment as that afforded to *Achimenes* and *Tydas*, when towards midsummer the plant should be turned out of its pot, shaking all the old soil away and sorting out the scaly tubers and repotting into 5½-inch pots, or put two or three of the largest tubers into 6½-inch or 7-inch pots, using similar soil to that given to *Gloxinias* in general, and grow on as one does *Achimenes*, giving a little fire-heat, with shade during bright weather. Give plenty of water when growth is active. Propagation is done by division of the tubers when repotting, or the tops may be taken off and rooted in the same way as one would the *Achimenes*."

SAXIFRAGA PELTATA.

Mr. Kingsmill sends from The Holt, Harrow Weald, a leaf of this *Saxifraga*. It is 23 inches across, and the stem is 44 inches in length. Mr. Kingsmill writes: "A large patch of this fine species has been strikingly handsome all the summer up till now. Close by it is a fine plant of *Gunnera manicata*, measuring 17 feet across. A careful measurement of the apparently largest leaf gave 63 inches across, with a stem of 70 inches from base of leaf to the plant itself. Both these plants are growing near the edge of a pond and in rather a shady situation."

DESMODIUM PENDULIFLORUM (SYN. LESPEDEZA BICOLOR).

A correspondent sends flowers of this interesting shrub, with the following note: "A graceful wall shrub, flowering freely at the end of September and through October, when most climbers are past. The shrub should be cut down to the ground in the winter, and in exposed situations protected with Bracken."

CALYSTEGIA FUESCENS FLORE-PLENO.

Mr. Field sends flowers of this beautiful plant, with the following note: "When visiting the gardens at Bitterly Court, Ludlow, a few days ago I was pleased to find this pretty double Bindweed there in all its glory. Planted against a low fence in a deep rich soil it was growing most luxuriantly. The flowers were quite 2 inches in diameter and of a rosy pink colour, and, unlike those of most of the members of this family, it is not difficult to keep within bounds. When planted in good soil it will often make shoots 8 feet or 9 feet long in a season, and continues to flower until quite late in the autumn. This plant is at home in the rock garden, and for covering low fences, roots of trees, and low bushes in the shrubbery borders it has few equals."

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

October 18.—Royal Horticultural Society, Meeting of Committees, 12 noon.

October 25.—Croydon Chrysanthemum Society's Show (two days).

October 27.—Exmouth Chrysanthemum Show.

November 1.—Bournemouth Chrysanthemum Show (two days); Brighton Chrysanthemum Show (two days); Royal Horticultural Society.

November 2.—National Chrysanthemum Society's Show at Crystal Palace (three days); Southampton Royal Horticultural Society's Show (two days); Highgate Chrysanthemum Show (three days); Lowestoft Chrysanthemum Show (two days); Portsmouth Chrysanthemum Show (three days).

November 3.—Weybridge Chrysanthemum Show; Colchester Chrysanthemum Show; Forest Gate Chrysanthemum Show (three days).

November 4.—Windsor and Eton Chrysanthemum Show; Battersea, Clapham, and Wandsworth Chrysanthemum Show (two days); Hiockley Chrysanthemum Show (two days).

November 5.—Batley and District Chrysanthemum Show; Loughborough Chrysanthemum Show; Penarth Chrysanthemum Show; North Lonsdale Chrysanthemum Show.

November 8.—Ipswich and East of England Horticultural Society's Show at Ipswich (two days); Dulwich Chrysanthemum Show (two days); Sevenoaks Chrysanthemum Show (two days).

November 9.—Buxton Chrysanthemum Show.

Royal Horticultural Society.—The next show and meeting will be held in the Royal Horticultural Hall on Tuesday next, when new Fellows will be elected, new and rare plants and flowers, fruits, and vegetables will be exhibited, and a lecture, illustrated by lantern slides, will be given by the Rev. Professor George Henslow, V.M.H., on "Geographical Botany as a Result of the Adaptability of Plants." At a meeting of the Council, held on the 4th inst., on the question of the terms to be allowed to special horticultural societies, it was decided to grant all such societies, when holding a show in conjunction with one of the Royal Horticultural Society's fortnightly meetings, the following: (1) Four transferable admission tickets to each £1 ls. subscriber to the special society; two transferable ditto to each 10s. 6d. subscriber; and one transferable ditto to each 5s. subscriber. (2) Ten pounds in money towards the prizes. (3) The Royal Horticultural Society will make no award to any exhibit which follows closely on any class under the special society's schedule; such exhibits must be entered with the special society. (4) The Royal Horticultural Society will provide and fix all staging, bottles, plates, &c. (5) The arrangement of the exhibits must be left entirely to the Royal Horticultural Society.—W. WILKS, Secretary.

Hemerocallis citrina species.—I received this fine hardy Chinese plant at the beginning of last year from Herr Sprenger of Naples, and during last summer it bloomed nicely, producing one spike bearing about sixteen flowers. During the summer now coming to a close, however, having now got fully established in my garden, it has bloomed very finely indeed, sending up two many-branched flower-spikes, bearing from thirty to forty blooms on each of them. The flowers are of a pale lemon yellow, and of a large size, with dark brown shadings on their undersurface. They are somewhat thin in texture, and extremely brittle, so that the plant should be put in as sheltered a position as possible, as if exposed to any high wind the long petals are apt to be torn or broken in two.—W. E. GUMBLETON.

Rhabdthamnus Solandri.—I have a very interesting and curious New Zealand plant now coming into flower for the first time. It is a shrubby *Gesnerad* *Rhabdthamnus Solandri*, with light orange tubular flowers, in form something like those of a *Tydaea*, a) with brown longitudinal bands. I got my plant from Lemoine of Nancy.—W. E. GUMBLETON.

A prolific Potato.—At Woodhouse, Eaves, Leicestershire, a farmer named Reynolds has just raised 136lb. of Johnson Diamond Potatoes, the produce of 1lb. of seed Potatoes cut into single eyes and planted. They were dug and weighed in the presence of several witnesses.—E. S. O.

Anemone japonica crispa.—This variety of Anemone is quite a novelty, and as such is interesting. It grows 1 foot high, has thick Parsley or small Kale-like leaves, the edges of which are quite bronzed, giving it a pleasing appearance. The flowers are rose-coloured.—E. M.

Erigeron salsuginosus.—There seems to be a difference of opinion as to which is the correct form of this Erigeron. The plant most commonly known as salsuginosus grows 2 feet high, and is in full flower now. In colour it is palest pink; it is much branched and very free, a valuable border plant for September and October. The variety Mr. Perry names salsuginosus is quite a different plant; it grows but 6 inches high, flowers in June, has a deep pink and a far larger blossom, and is much more sparse of flower. The "Kew Hand List" says both forms are from North-Western America, and the tall form is a variety—Howellii. A little information would be appreciated.—E. M.

Desmodium penduliflorum.—During September flowering shrubs are not plentiful, and it is surprising that one does not see this beautiful Japanese species more frequently used, for at this season it certainly forms one of the most noteworthy subjects in the shrubbery. The flowers are Pea-shaped, rosy purple in colour, are produced very freely along quite 3 feet of the stems from the tip, and remain for a considerable time in good condition. In a strong soil here the slender stems annually reach a height of fully 7 feet, and need supporting, but I have seen this shrub used with good results when planted on the grass and tied over a framework. The stems die down to the ground with us in winter and need close pruning, though there is little doubt that this excellent shrub is perfectly hardy in all but the very coldest parts of these islands. It is also known as *Hesperis bicolor*.—A. E. THATCHER, *Elstree*.

Aster Finchley White.—Among the Michaelmas Daisies there are numerous white forms, especially of the *Novi-Belgii* and *lavis* types, but none of them can compare in excellence with this new variety, which originated in the Finchley Nurseries of Messrs. Cutbush and Son last year. The flowers are of the purest white and fully 2 inches across, and, being produced with remarkable freedom, a fine show of bloom is obtained. The growth is compact and reaches a height of between 4 feet and 5 feet, and the roots do not spread so freely as with the older sorts. I am sure this variety will be much appreciated where the best large-flowered Asters are desired.—A. E. THATCHER.

Fruit at the Dairy Show.—We noticed a fine stand of fruit put up by Messrs. Hugh Low and Co., Bush Hill Park, at the Dairy Show held in the Agricultural Hall, which consisted mostly of Apples, of which Blenheim Orange, Worcester Pearmain, Cox's Orange Pippin, and Warner's King were excellent. Laue's Prince Albert and Bismarck, although well coloured, were smaller. The exhibit, which included a few trees of Apples, Pears, and Vines fruiting in pots, was evidently got up to attract the market growers who throng this exhibition in greater numbers probably than any similar show of its kind. Other nurserymen showing were Messrs. W. and J. Brown of Stamford, who put up a miscellaneous group, which included their new Cactus-flowered Geranium.

Public bowling greens in Edinburgh.—Much notice is taken by visitors to Edinburgh of the various public bowling greens provided by the corporation in different parts of the city and of the large number of players who frequent them. Practically all parts of the city are within easy reach of one or more of these bowling greens, which supply a valuable opportunity of recreation in the open air during the summer. From time to time additions have been made to

their number, and these additions have caused a considerable amount of work to Mr. J. W. M'Hattie, the able city gardener, in whose department the management of the bowling greens is vested. This year the success of the greens has been greater than ever, and during the season which has just been concluded 198,037 players took part in the games, an increase of 36,497. The revenue has also been considerably more, amounting this season to £825 3s. 1d., or £152 18s. 1d. above last year. The continued success of these greens is properly a cause of much gratification to those members of the corporation who have consistently advocated their formation.

Orchids in the market.—During the past few weeks Orchid flowers have been very plentiful. One salesman told us that he was receiving large supplies of *Odontoglossum grande* from one grower, but the trade for them was very poor. The flowers seen were very fine. About fifty dozen per week have been sent, and if trade warranted it much larger supplies could be sent from the same grower. Displayed in some of the florists' windows with *Asparagus* and other foliage they look very pretty, but the colour is not quite what is wanted. *Cattleya labiata* sells better, but even with these there is a limit to the demand, and just now is perhaps the worst time of the year for selling choice things. It is surprising how beautiful these work up in almost all floral arrangements. In funeral emblems they are now used extensively, and probably the largest portion at present are for this work; there would be little trade for them if it were not for this. *Cypripedium insigne* is another which is now seen in the market, also *Phalaenopsis schilleriana*. Considering the long time they last, Orchid blooms ought to make better prices. It is the *Cattleyas* of a mauve shade and *Odontoglossum crispum* which find most favour with florists.

Amalgamation of Hawick horticultural societies.—For some time the border town of Hawick has been the sphere of operations of two horticultural organisations, the Hawick Horticultural Society and the Hawick Working Men's Allotment and Cottage Garden Society. Although, to some extent, these worked on different lines, it has been felt that union would be very advantageous, and would tend to strengthen the movement to advance horticulture in the town and district. Negotiations between the two were entered into, and at a meeting held in the Burgh Court Room, Hawick, on the evening of the 28th ult. the proposals for amalgamation were approved of, and a new society was formed under the title of the Hawick Horticultural Society, the shows to be open to all districts. A committee and office-bearers were also appointed, the committee consisting of five gardeners and five amateurs, the office-bearers being: President, Mr. John Turnbull, Beaconsfield Terrace; vice-president, Mr. John Forbes, Buccleuch Nurseries; secretary, Mr. William Oliver; treasurer, Mr. George Davidson. There is every prospect that the society will be well supported in the locality.

Transmission of variegation by grafting.—M. Lindemuth recently wrote to the Royal Horticultural Society of Prussia concerning his experiments in grafting, experiments which he has conducted for several years. M. Lindemuth in these experiments made use especially of *Abutilon Thompsoni*, the variegation of which has been communicated in many cases to other Malvaceæ upon which it has been grafted. An attempt with *Sida mollis* has given doubtful but, nevertheless, very interesting results. The fusion of the graft with the stock was not complete; the graft showed a tendency to free itself and developed many adventitious roots, which would, indeed, have freed it had they been allowed to grow. The variegation was conveyed to the stock in a curious manner. The first shoot below the graft became variegated; the second, a little lower down, was likewise variegated with yellow; but the third shoot, still lower down, remained green. M. Lindemuth has communicated to the society some general observations on the transmission of variegation by grafting. He has known five different cases. In the first the variegation

was not transmitted—this is generally the case; in the second all the subjects became variegated; in the third some became variegated, others remained green; in the fourth the variegation was communicated in a latent state, and did not appear before the end of several months; and in the fifth some species contracted the variegation to such a pronounced degree that they really became diseased; the leaves fell in the yellow state, and the plant soon died.—*La Revue Horticole*.

Polygonum baldschuanicum.—The reference to this plant by Dr. Mules on page 202 of THE GARDEN of the 24th ult., and his remark that some of his friends tell him they cannot grow it, and decay it accordingly, leads one to say that it seems to require a considerable amount of moisture to enable it to grow and flower freely. I have observed it in a considerable number of gardens, as well as in my own, and I am satisfied that it frequently receives too dry treatment. With me in a very dry place it makes little growth and has flowered poorly, while in a garden in this vicinity it rambles over a tree, blooms freely, and is exceedingly beautiful; there it is in a moist and peaty soil. I shall remove my plant in spring, and I have little fear of succeeding with it under moister conditions than it at present has. I hope, however, that others will give the result of their experience.—S. ARNOTT.

Campanula pulloides.—A small plant in a pot, such as that figured on page 203, excellent as is the photograph, hardly does justice to this pretty little Campanula, which deserves all the commendation given it by Mr. Wood. It was raised by Mr. T. H. Archer-Hind, who very kindly sent it to me some year or two ago, and, although it seems to be of the same parentage as that of the forms of the hybrid C. G. F. Wilson, it is distinct from these, and quite equal to the best of them. It will thrive in the soil and with the treatment Mr. Wood indicates in his interesting note in THE GARDEN of the 24th ult. On a rockery it will soon form a good plant, and when in bloom is charming.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Pardanthus chinensis.—This plant, which was introduced about eighty years ago, is very rarely met with in gardens, and the last fifty-two volumes of THE GARDEN contain no mention of it. Last month I saw it near Chepstow, and found it very strong in Canon Ellacombe's wonderful garden at Bitton. It is now in flower with me, and is distinctly pretty. It grows to a height of 18 inches or 2 feet, and its flowers, which are orange, spotted with crimson, from which colouring it takes its name, are about 2 inches across, several being borne on a branching stem. They are, unfortunately, fugitive, only lasting in beauty one day, but are produced in quick succession. It belongs to the order of Iridiæ, and its foliage and habit resemble an Iris. Since it succeeds in Gloucestershire, it is probably fairly hardy. With me it is growing in a sunny border in light soil.—S. W. FITZHERBERT.

Stigmaphyllon ciliatum.—This, known sometimes as the Golden Vine, is a free-growing climber from Brazil, which needs, as might be expected from its native habitat, the temperature of a stove or at least of an intermediate house. It was introduced over a century ago, but is by no means common in gardens; still it seems to be the only member of a fairly extensive genus that is in general cultivation. The leaves are oppositely arranged, somewhat heart-shaped, smooth, except at the edges, where they are fringed with numerous hairs, colour pale green, suffused with a glaucous hue. The flowers, which are borne five or six in a cluster, are about 2 inches across and of a clear yellow colour. Singularly enough they much suggest in shape the flowers of some of the *Ocuidiums*. When in good condition this *Stigmaphyllon* will soon cover a considerable space, and flower throughout the greater part of the summer and early autumn. In any selection of warm house climbers it is well worth a place, as apart from any other feature it is perfectly distinct from all other stove or greenhouse plants of this class. Its cultivation is not exacting, still it is seen to greater advantage when planted in a prepared border than if treated as a pot plant. During the spring and summer

BENTHAMIA FRAGIFERA AT TRELISSICK, TRURO.

months a liberal use of the syringe is necessary, as the foliage is rather liable to be attacked by red spider, which soon causes the leaves to turn yellow and drop, but which can be readily kept down by syringing. Cuttings of this plant root without difficulty.—T.

Lysimachia Fortunei.—I was glad to see the interesting mention by Dr. P. H. Mules of this new *Lysimachia*, which I obtained last autumn. It has flowered well this season, and is still in bloom. It is in some respects like *L. clethroides*, but it has also a character of its own, and is more distinct than most of the members of the genus. It is not a showy plant by any means, but its spikes of small white flowers, with dark brown anthers, are pleasing. At a distance they make some think that the plant is a *Veronica*, but a glance at the character of the flowers is sufficient to correct this impression. The leaves resemble those of some of the *Willows*. It is a plant which should grow between 2 feet and 3 feet high in ordinary soil. For its possession I am indebted to Mr. Max Leichtlin of Baden-Baden, who has enriched so many of our gardens by his introductions.—S. ARNOTT, *Cursethorn, by Dumfries, N.B.*

Astilbe Davidi.—Fuller experience of this splendid *Veitchian* introduction confirms the opinions expressed when this *Astilbe* was first exhibited in London, and there can be no doubt that it is the finest thing in hardy plants that China has given us of late. It appears to thrive in any well-tilled soil, appreciating to the full a root run of leaf-soil and well-decayed manure; in fact, one cannot treat the plant too well to get excellent results. The leafage is robust, the plumes immense, and their colouring is of a peculiar shade, rosy purple marked with blue and silvery rose. The panicles are not so dense as in most *Astilbes*. It is not too much to say *Astilbe Davidi* will be found in every garden worthy of the name ten years hence, and it is probable that a new race of coloured *Astilbes* of still greater value may result from crossing this plant with *chinensis* and others.—G. B. M.

Early Pompon Chrysanthemum J. B. Duvoir.—Since it was introduced in 1891 by M. Simon Delaux, who gave us so many excellent early *Chrysanthemums*, little has been heard of this variety. I well remember making a note of its promising character on the occasion of its first

flowering in this country, but in the interval the only place in which the plant was found was in the representative collection of Mr. William Sydenham of Tamworth, who has had it in his trial for three years now. Of the *Pompon* type of this early edition of the *Autumn Queen* the variety under notice is one of the very best. The flowers are just a trifle larger than most other sorts, yet they are excellent representatives of the type. The colour may be described as pale blush-pink, and each flower is borne on a long erect foot-stalk. During September, from the earliest days, the plant is a picture, never failing to please those who see the display. Its height is 18 inches.—D. B. C.

Early-flowering Chrysanthemum Improved Masse.—This is a seedling raised by Mr. H. J. Jones at Ryecroft Nursery, a plant or two of which was sent to me for trial. The seedling plant was distinctly promising, but the specimens now in flower in my own collection are all that the descriptive name of the variety says of it. The flowers are larger and better in every way than those of the type, being of excellent form, and of more pleasing colour than those of *Mme. Marie Masse*. This new sort may be regarded as a distinct acquisition, the plant being branching and sturdy, and the flowers are each borne on a long erect foot-stalk. Height of plant less than 3 feet.—D. B. CRANE.

The Pomegranate.—Here in South Hants, within ten miles of the Solent, the *Pomegranate* is quite hardy at the foot of a south wall without any further protection. As a rule it gives a crop of its brilliantly coloured blossoms in August, but I never saw it fruit here. In Mr. J. Moss's garden at Wintershill House, near Bishop's Waltham, the finest plant I ever saw of it used to grow at the east end of a greenhouse. It was smothered with blossoms almost every year. At Aldenham in Herts, it grows on the western side of a low terrace wall, but is not yet large enough to flower.—E. M.

Runner Bean Lye's Favourite.—I recently saw this *Bean* growing at Aldenham, and believe it to be the variety raised by Mr. Lye at Sydmonton. It is grown both by Mr. Pope and Mr. Beckett, and both speak highly of it. The latter says it is the finest *Bean* in existence. I measured some hanging on the plants at Aldenham,

and they were 1 inch longer than a foot-rule. I am glad to see "A. D." speak so highly of this *Bean*.—E. M.

Apple Tom Putt.—This Devonshire *Apple* has done remarkably well this year; it has borne freely, and the fruits have coloured extremely well. It is difficult to name a more showy *Apple*. The skin is a brilliant crimson, suffused with clear yellow. It is not only good looking, but really a good cooking variety, in use in October and November. In this neighbourhood an *Apple* named *Profit* is somewhat largely grown; it resembles *Tom Putt* in every way, except that it lacks colour. Does anyone know the origin and history of *Profit*?—E. M., *South Hants*.

Early flowering Chrysanthemum Snowflake.—This promises to be one of the best white-flowered varieties for an early crop. The growth is compact, sturdy, and not more than 3 feet high; it flowers abundantly. The flowers are about 5 inches in diameter, with somewhat narrow, semi-drooping petals, with pointed tips, and of the purest white. It is one of Mr. Godfrey's seedlings.—E. M.

Exhibition of Colonial fruits.—The Colonial-grown fruit show organised by the Royal Horticultural Society, which is announced to take place on December 13 and 14 next, will include such fruits as Colonial-grown dessert *Apples* and cooking *Apples*, *Pears*, *Pineapples*, *Bananas*, *Mangoes*, *Grapes*, *Yams*, *Sweet Potatoes*, and other fruit. In connexion with this there will

also be a show of preserved and bottled fruits and jams open to the Colonies, the home country, and to foreign countries as well. We understand that a second show of Colonial-grown fruit is in contemplation to take place about the end of March or the beginning of April of next year, in order to give every opportunity for the exhibition of such fruits as may not be in season in December.

Buddleia variabilis veitchiana.—It may be interesting to some to know that this fine *Buddleia* withstood last winter's frost in the Royal Botanic Gardens, Edinburgh, on the wall of the terrace in front of the range of plant houses. It has grown vigorously, and was still in flower as late as the middle of September. It is much better than the typical *B. variabilis*, while it appears also to be harder than that form. Its purple racemes are very ornamental, and it deserves the notice of lovers of shrubs who are desirous of adding the best of the newer plants. In some places it may need a little protection, though this should be avoided if possible.—S. ARNOTT.

TREES AND SHRUBS.

BENTHAMIA FRAGIFERA.

SOME years ago a coloured plate was published in *THE GARDEN* of the fruit of this beautiful tree, and by request I sent some of the berries to Kew, one half of which were preserved in the museum there and the other half in the museum at Washington, U.S.A. I was afterwards informed that not one of the Kew authorities had ever seen the fruit before. This *Benthamia* was introduced from Nepal about eighty years ago, and the original plant grew for many years at Helligan, in Cornwall. The tree died, but was allowed to stand as an object of curiosity. The shrub, or rather tree, for it grows here to 25 feet high and as many through, is very beautiful in the month of May, with its cream-coloured flowers about the size of a *Petunia*, but still more beautiful in December, when the branches are laden with the brilliantly coloured fruits, about the size of

those of an ordinary Strawberry. Birds, however, are very fond of it, and will soon destroy them unless means are taken to scare them away. Unfortunately, the tree is not quite hardy, and can only be seen in perfection in the south-west of England. It is not at all particular as to soil, and grows freely from seed. The photograph is by Mr. Mewton of Truro.

Trelissick, Truro. WILLIAM SANGWIN.

CISTUS LADANIFERUS.

I ENCLOSE a photograph of what I consider a magnificent plant of the above; indeed, I have never seen one to equal it. I have known this plant for some twenty-five years; it is growing in the gardens of J. E. Cokayne, Esq., Exeter House, Roehampton. It measures 5½ feet in circumference, and is 8 feet 6 inches high. On a fine day when at its best it is truly a beautiful sight.

VICARY GIBBS.

Aldenham House, Elstree.

BULBS FOR THE GREENHOUSE.

TO have a display of flowers throughout the year in the greenhouse or conservatory it is necessary to rely greatly on bulbs for a certain period; indeed, during the first three months of the year bulbous plants furnish the major portion of the floral display. Nearly all of them so used are perfectly hardy; that is to say, the protection of a greenhouse is not absolutely necessary to their well-doing, but by the protection thus afforded they anticipate by a considerable period their natural season of flowering, and are, consequently, particularly welcome. The hardy kinds are largely grown in Holland and in some parts of this country; in fact, their cultivation here is greatly on the increase. When dormant they are lifted, dried, assorted, and are then ready for sale. Though numbers are disposed of before that time, the bulb season as a rule may be said to commence in September, and, though they may be obtained for a long time after that, the best month for potting the greater portion is October, as after that time they deteriorate if kept in dry store-rooms, warehouses, &c. As the bulbs when fully grown contain the embryo flowers, it is evident that the principal consideration is to place them under such conditions that they will grow and develop their blossoms without check, but, as the same treatment is not applicable to all, the requirements of each class will be separately dealt with. Of hardy bulbs available for greenhouse decoration the principal are Hyacinth, Tulip, Narcissus, Crocus, Allium neapolitanum, Chionodoxa, Scilla, Snowdrop, Muscari, and Liliums.

HYACINTHS may be potted singly into pots 4½ inches or 5 inches in diameter, while for decorative purposes three bulbs are sometimes put in a large pot and arranged triangularly. A mixture of loam, leaf-mould, well-decayed cow manure, and sand will suit Hyacinths well, and in potting it should not be pressed down too firmly. The bulb should be planted at such a depth that the top is just on a level with the surface of the soil. After potting place them on a bed of ashes out of doors, give a good watering through a rose, and when drained they may be covered to a depth of 4 inches with cocoa-nut refuse. This is not absolutely necessary, for I have seen good results by simply standing the pots outside till the bulbs were well rooted. In any case this will take from a month to six weeks, when they should be lifted and the pots placed in a cold frame or taken direct to the greenhouse, where they must be given a light position. As the pots get full of roots an increased amount of water will be needed, and liquid manure may be given occasionally. If required early, forcing will, of course, be necessary, but where there are no facilities for this they may be allowed to develop in the greenhouse, and in a temperature

of 50° to 60°, or even less, they give but little trouble, and with ordinary attention can be depended upon to do well. A selection of Hyacinths for pot culture would include:—Single: Alba maxima, white; Avalanche, white; Ball of Gold, yellow; Charles Dickens, light blue; City of Haarlem, yellow; Czar Peter, lavender-mauve; Fabiola, pink; Garibaldi, bright crimson; General Havelock, deep blackish purple; gigantea, rose; General Pelissier, crimson; Grand Vedette, white; Grandeur à Merveille, blush-white; Grand Lilas, porcelain blue; King of the Blues, dark blue; King of the Blacks, darkest of all; Koh-i-noor, salmon-pink; Leonidas, bright blue; L'Innocence, white; Macaulay, rose, striped carmine; Norma, waxy pink; Queen of Hyacinths, rosy scarlet; Ruby Queen, rich ruby-red; and William III., deep purple. Double: Blocksberg, porcelain blue; Bouquet Royal, light rose; Empress of India, carmine; Garrick, lilac-blue; La tour d'Auvergne, pure white; Lord Beaconsfield, deep red; La Grandesse, white; Laurens Koster, dark blue; L'Adorable, pure white; Noble par Merite, pink; Princess Louise, carmine-red; and Prince Albert, purplish black.

HYACINTHS IN GLASSES.—Grown in this way Hyacinths are admired by many, and if two or three simple facts are borne in mind failures will be but few. In the first place, single-flowered varieties are far more likely to give satisfaction than the double ones. Well-shaped bulbs should be chosen for this purpose. Then fill the glass with water so as almost to touch the base of the bulb, putting at the same time a small piece or two of charcoal in the glass, as this tends to keep the water pure. After putting the bulbs in position the glasses should be kept in a cool, dry, dark place till the roots nearly touch the bottom of the glass; then they should be brought gradually into the light, afterwards giving them plenty of light and air, but keep from direct draughts. The water will need replenishing occasionally, but will not require changing as long as it keeps sweet. Occasionally a little decay appears, and this should be removed as soon as detected. As the flower-spike lengthens it should be supported by a wire, otherwise it may get top-heavy and fall over.

ROMAN HYACINTHS.—Though the bulbs of Roman Hyacinths are sent to this country in great numbers, the earliest usually reaching here about the end of July, a good deal of misconception prevails as to their requirements, for, flowering early as they do, hard forcing is generally considered necessary, whereas even the amateur with but a single greenhouse can readily have them in flower long before Christmas. In potting the Roman Hyacinth

three fair-sized bulbs may be put in a pot 5 inches in diameter, and so treated they form effective clumps, for several spikes are pushed up from one bulb, a succession being maintained for some little time. Larger pots, with a corresponding increase in the number of bulbs, may be used if preferred. To maintain a display of flowers a fortnightly potting may be made from the end of August to a corresponding period in October. After potting they are usually placed out of doors and treated as other Hyacinths are.

TULIPS.—Generally speaking, Tulips grown in pots require much the same treatment as Hyacinths, except that from three to five bulbs may be put in a pot 5 inches in diameter. Like the Hyacinths, too, they will develop in an ordinary greenhouse from which frost is excluded, and it is most interesting to watch their gradual development at a time when nearly all outdoor plants are dormant. Of the different varieties of Tulips suitable for pot culture, the old Duc Van Thol, whose flowers are red, edged with yellow, has been long popular for the purpose; it is one of the earliest flowering of all Tulips. For some years this stood out by itself, but now the Duc Van Thol race embraces many colours, there being the crimson, orange, scarlet, rose, and yellow, all of which are equally desirable with the typical form. In addition to these, the following are all good for pot culture: Single: Belle Alliance, deep scarlet; Bride of Haarlem, white, striped and feathered crimson; Brutus, orange-crimson, narrow golden margin; Cerise Grisdelin, cerise, yellow margin; Chrysolora, clear yellow; Cottage Maid, rose-pink, shaded white; Crimson King, scarlet-crimson; Joost Van Vondel, rosy crimson; King of Yellows, golden yellow; Koh-i-noor, rich scarlet; L'immaculée, pure white; Proserpine, rich dark rose; Rosa Mundi, purplish rose; Rose Grisdelin, rose, flushed white; Royal Standard, white, feathered crimson; Thomas Moore, orange, shaded scarlet; Vermilion Brilliant, bright vermilion; Van der Neer, purplish violet; and White Swan, pure white. Double: Scarcely so well adapted for pot culture as the single kinds; still, they are admired by some. Couronne des Roses, deep rose; Duc Van Thol, red and yellow; Gloria Solis, reddish brown; Imperator Rubrorum, bright crimson; La Precoce, pure white; Le Matador, orange-scarlet; Murillo, pale rose; Prince of Wales, orange-scarlet, edged yellow; Raphael, rose; Rex Rubrorum, bright red; Tournesol, red and yellow; and Tournesol Yellow, bright golden yellow.

NARCISSUS.—The members of this genus, regarded as pot plants, may be divided into two classes; firstly, the Polyanthus Narcissi, some of which are

CISTUS LADANIFERUS AT ROEHAMPTON. (From a photograph sent by the Hon. Vicary Gibbs.)

very amenable to forcing. They bear a quantity of flowers on a single stem, and are very valuable for decorative purposes. The second class consists of the innumerable varieties which may be flowered under glass, but will not bear hard forcing. The different forms of *Polyanthus Narcissi* may be treated as recommended for *Hyacinths*, except that they should be buried somewhat deeper in the soil. The best varieties are Early Double Roman, white, with orange centre; Early Paper White, pure white; Early Snowflake, pure white, larger than the preceding. These three, if gently forced, may be had in bloom by Christmas, while the following will not be far behind: Bathurst, clear light yellow, with orange cup; Distinction, pure white, with deep orange cup; General Gordon, orange-yellow; Grand Monarque, pure white, citron cup; and White Pearl, pure white. To this section belongs the Chinese Sacred Narcissus, known as the Fairy Lily, Joss Flower, and Flower of the Gods. This is always imported direct from China or Japan, and usually arrives about the end of the year. The Joss Flower will readily develop and flower well if the bulbs are put in small bowls of water with some pebbles in the bottom to hold the bulb in position. If kept indoors it should be placed in a light window, otherwise the leaves and flower-stems become weak, and a good deal of their beauty is lost.

H. P.

(To be continued.)

A GENERAL CALENDAR.

PLANTING FRUIT TREES.

AFTER the rains we have experienced of late the ground should now be in good condition for planting. The best time is from the latter part of October to the middle of November, according to the season. It does not matter if all the leaves are not off; in fact, I prefer planting while the leaves are still on the trees. They should be planted as soon as they arrive from the nursery, or, if they have to wait for a time, the roots should be covered over with damp matting or leaves, for on no account should the roots get dry. Never be tempted to buy fruit trees at an auction room, where the roots have been exposed perhaps for days together. It is very rare indeed for fruit trees which have been subject to this treatment completely to recover from it.

Gooseberries.—In every garden there should always be a good quantity of Gooseberries. The large early ones come in for gathering when green, some are valuable for dessert when ripe, while others are useful for preserving. In many gardens it is difficult to find room for everything required, as the demand far exceeds the convenience for production, but with a little forethought it is astonishing what an amount may be grown in a limited space. Cordons planted against low fences or along the edges of walks take up little room; they will give a quantity of fruit if planted against north walls and similar positions where the fruits can be protected from autumnal rains. Before planting the ground should be deeply dug and well manured, for it is astonishing the amount of nourishment a heavy crop of Gooseberries requires.

Planting Cudlflowers.—It is time that the first batch of Early London, Walcheren, or Early Erfurt intended for use at the end of May were transplanted. When the plants have been pricked out into beds they may be lifted with a fair amount of soil adhering, and should feel the check of removal but little. Plant firmly and sufficiently deep to prevent the plants swaying to and fro through autumn winds, give a gentle watering to settle the soil round the roots, and keep the lights off the frames for the present. Should, however, frost or rough weather set in, the lights may be placed on in such a position as to admit a little air.

Pricking out Cabbages.—After the required area has been planted with plants from the seed-beds those that are left may well be pricked out closely on well-prepared firm ground in sheltered nooks

to stand the winter, as, should the weather prove mild, these are often of more value in spring than the ones wintered in frames, being hardier and doing far better when transplanted.

Pyrethrums.—Where an early display and an increased stock of these is required autumn division is preferable, especially if the spring should prove hot and dry. The clumps should not be split up any more than is absolutely necessary, so as to avoid mutilation as much as possible. A deep rich soil suits the *Pyrethrums* best. The plants are very sensitive to a long spell of dry weather, and I find a good surface mulching indispensable to successful culture.

Schizostylis coccinea.—This charming autumn-flowering plant is rarely seen now. Its neat spikes of bright crimson or deep scarlet-hued blossoms give a note of colour in the outdoor borders at a time when this is of unusual value. It grows freely in any good garden soil, and should be planted in the spring or early summer, increase being obtained by means of division. If planted rather late in good-sized pots, grown on in a cool pit during summer, and brought into the greenhouse in the early autumn when just showing bloom, it expands beautifully and contrasts admirably with *Chrysanthemums*. Plants lifted now from the borders and placed firmly in pots and well watered will soon recover themselves and give an abundance of bloom through the autumn and early winter months.

Pampas Grass.—When it is desired to gather the Pampas plumes for decoration they should be cut when quite dry just as they are about to expand, and then gently shaken out of their protecting sheaths before a fire. If this is done slowly and carefully they lose none of their beauty and last much longer than when left to open in the usual way.

Norwich.

T. B. FIELD.

THE HAMMOCK UNDER THE OAKS.

SOME AUTUMN FLOWERS.

(Continued from page 243.)

NEARLY all the different kinds of Sunflowers are now out of bloom, but *Rudbeckia hirta* is still making patches of gay colour in the wild garden with its orange-coloured blossoms which have black centres. It is by way of becoming a nuisance, as it seeds very freely in good soil, so that it is necessary to discipline it severely to keep it within bounds. However, it is not hard to eradicate, and will not prove such a pest as a marsh Golden Rod in one of the Iris beds. The roots of this Golden Rod came in a waggon load of black, peaty soil from the marsh, which was used some years ago in the formation of this Iris and *Pæony* bed. Last spring the entire bed had to be gone over very carefully to destroy the Golden Rod. It increased rapidly by means of underground stolons, the roots spreading in all directions from a central stalk, which reminded me of nothing so much as of the long arms of an octopus. Their hold upon the ground was amazing, and they had worked their way far under the fleshy rhizomes of the Irises. These had in many cases to be pulled all to bits to rid them of the embrace of the Golden Rod.

Even more disastrous is the mischief done in the rock garden by an innocent-looking little creeper, which has spread during a summer's neglect to such an extent that much of the rock garden will have to be dug up and replanted. This treacherous plant is a wild ground Ivy (*Glechoma hederacea*) which belongs to the Mint family. It is a native of our damp woodlands, and has spread from one small rootlet brought some years ago from the

river cliffs in a basket of Ferns, Columbinas, and other treasures for the rock garden. First it took possession of the winding path through the rockery, which it clothed in such a dainty green garment, bespangled in spring with such pretty blue labiate blossoms, that it was allowed to have its way. Then it gradually invaded long-established beds of Moss Pinks, hardy Alyssum, *Saponaria ocyroides*, and such things, running over the tops of low-growing plants, its runners rooting everywhere, until it would entirely cover a bed, overshadowing the invaded plants in such a way as to rob them of light and air. The only way to treat such an encroacher is to give no quarter. Not a single root must be left alive.

A great clump of tender *Hibiscus*, 6 feet in height, has been in flower for a fortnight from seed planted in the open in May. This is *Hibiscus africanus*, an annual, and a large group of it is quite an imposing ornament for a flower-bed or border of mixed shrubs, large annuals, and perennials. The five-parted leaves are as large and showy as those of the Castor Bean, and the big flowers, which are lemon yellow with centres of very dark maroon, are strikingly pretty. The great plants have hundreds of buds yet to open from the many-branched stems, but it is probable that they will soon be cut down by the frost. To obtain the best results from this *Hibiscus* the seed should be sown in February under glass, and the plants transferred to the open late in May.

Few individual plants have given us so much pleasure as the great Evening Primrose spoken of in my last letter, which the little girl and I used to watch under umbrellas in the rainy summer twilights. It reached the height of its beauty one night in July, when forty-eight of its large, lemon yellow blossoms expanded slowly under our eyes, from its main stem and many side shoots. This *Oenothera* is a biennial, and is now quite dead, but it is easily raised from seed, which should be sown every year in order to keep up a succession of young plants.

Another bit of beauty that has afforded us much pleasure is a part of the gently sloping bank which we pass on our way to the hammock, which is planted with *Tritomas* in several varieties, the ground under them carpeted with orange and scarlet *Nasturtiums*. The effect of the orange and red *Tritomas* rising out of the bed of *Nasturtiums*, with flowers of the same colouring, has been very fine for a long time. The *Tritomas* used are *T. Uvaria grandiflora*, *T. corallina*, *T. Tuckii*, *T. Macowanii*, *T. Rooperi*, *T. nobilis*, and *T. Pfitzeri*. By using so many sorts one can have these showy plants in bloom from June until hard frost destroys the blossoms.

DANSKE DANDRIDGE.

NOTES ON HARDY PLANTS.

PENTSTEMON NEWBURY GEM.

MR. ERNEST LADHAMS of the Shirley Nurseries, Southampton, first exhibited this *Pentstemon* in the south of England some six years since, and in a conversation with him he said he found it in a garden at Newbery in Berks, or Messrs. Backhouse's traveller from York did; I forget which. This is how it got the name of Newbury Gem. At that time I looked upon it as a new plant. I grew it and recommended it to my friends. Guess my surprise when four years ago, calling on Mr. Shingler at Melton Constable in Norfolk, I found this same plant largely used for bedding. Mr. Shingler told me then he had grown it for forty years. It is a

grand plant for any purpose. I saw it largely used this summer for covering the soil in a large bed planted with white Fuchsias, and very effective it was. Neither wet nor drought seems to affect its growth and flowering. It strikes very easily from cuttings, and is perfectly hardy. My original plant is still growing and giving flower-spikes, though they are not so fine as those produced by year old plants. E. MOLYNEUX.

ANEMONE JAPONICA ROSEA SUPERBA.

THIS variety was distributed some years ago by M. Lemoine of Nancy. I believe that one of the parents was A. Lady Ardilaun, the other being the old rubra. Curiously enough, a seedling of mine is identical with it. It was the first cross I made, and saving the seeds late in the summer I got but one plant from them. I did not think much of it, but a person to whom I sent a plant later expressed a high opinion of its decorative worth. Later on I obtained the plant, which had been distributed under the above name, and I have never been able to distinguish any difference between them. This Anemone has all the good qualities a garden flower should possess. It is very hardy, quickly increases, and is extremely floriferous. The soft shade of pink which the flowers have is very distinct, and much like what one sees in some of the single Chrysanthemums. J. CORNHILL.

TULIP LA CANDEUR.

UNDER this name there are three quite distinct Tulips in the trade, and all are white. When ordering the variety recommended on page 188 in your issue for the 17th ult., it will be necessary to state that the double one is required. It grows about 1 foot in height, and is only about a quarter the price of the other two. The Darwin La Candeur, also known as White Queen, is single, and often grows to a height of 2 feet. It has large, bold, globular flowers, with black anthers. The May-flowering variety La Candeur is also single; it grows about 15 inches in height. It is perhaps met with more frequently under the name of Parisian White. A. OSBORN.

HERACLEUM LEHMANNIANUM.

THE members of the family to which this stately plant belongs are not conspicuous for the attractive colouring of their flowers. The lack of this feature, however, is amply compensated for by the noble proportions attained by many of them. By reason of this they are not adapted for the border or flower garden, but are suitable for the wild garden or for growing in open woods or by the side of streams. Naturalised in this way they are very effective with their handsome foliage and stout, branching stems, varying in height from 6 feet to 12 feet. At the top is an immense umbel of usually white flowers, followed later on by the smaller lateral heads springing from lower down the stem. A numerous family, the Cow Parsnips are spread over the mountains of Central and Southern Europe and Asia, with a single representative in this country commonly known as Hogweed (*H. Sphondylium*). In the accompanying illustration *H. lehmannianum* is shown on a dry bank, where it makes an effective picture. It is a native of Turkestan, and has been in cultivation for about six years. Growing in its present position from 6 feet to 7 feet high, the flowers of this species are freely produced and are dull pink in colour. The most common one in cultivation is probably *H. villosum*, which often passes under the name of *H. giganteum*. It is a native of the Caucasus, and is truly a gigantic plant. Both plants seed freely, and when undisturbed soon form large colonies, seedlings coming up in profusion all round and some distance from the old plants. It is a pity that these remarkably handsome plants are not more freely naturalised, as they will grow in positions quite unsuitable to many things. A single specimen standing out by itself is full of beauty, both with regard to its leaves, flowers, and stem. W. IRVING.

THE FLOWER GARDEN.

HARDY FLOWERS FOR CUTTING.

GARDENERS often regard with aversion the cutting of flowers for the house. The taste for cut flowers in the house has grown much during the last generation, and is no less remarkable than the alteration in the ways of arranging them. Something seems lacking in a house now, at least, in a living room, if there are no flowers in it, and nowhere is this more noticeable than on the dinner or tea-table. A small portion of the vegetable garden should be formed into a reserve garden, and devoted to small plots of certain flowers which demand special culture, that is, plants which will not do well in the ordinary herbaceous border, as these can only be properly manured, say, once in a half dozen years, when the whole of the plants are taken up and replanted. By means of this reserve garden well-cultivated plots can be given to choice flowers, which will grow with a luxuriance impossible in the mixed borders and beds, the former often filled with the roots of hungry shrubs. Flowers

HERACLEUM LEHMANNIANUM ON A DRY BANK.

for cutting will appear in such plenty that there will be ample provision for all the needs of the house, even on the most lavish scale, as well as a surplus wherewith to gratify one's less fortunate friends and cheer the sick poor withal.

My object in this article is to give a list of plants which can be easily grown and are suitable for cutting with an eye to effect in the house. The term hardy perennial is used instead of herbaceous perennial, as the latter strictly does not include bulbs or plants which remain green all the winter. For the first

THREE MONTHS OF THE YEAR

we are dependent almost entirely upon bulbs—Snowdrops, Crocuses, and the old-fashioned Daffodils, the latter in many people's opinion still holding their own for indoor decoration, notwithstanding the enormous vogue of the more delicate forms of Narcissus. Crocuses are awkward things to arrange as a rule, but if a flat vessel after the style of a soup plate is covered with the crowns of Carrots a week or two before the Crocus season, and these are kept moist in a warm room, a very

pretty green mass is obtained, and Crocuses stuck in it look very nice, and it might easily be supposed they were growing. They can be renewed day by day with little trouble. Daffodils look best in a bowl with a piece of felled lead at the bottom to keep both leaves and stems in a more or less upright position, thus giving them the appearance of growing in the bowl. But even for the first three months of the year we are not absolutely dependent upon bulbs, for the Christmas Rose (*Helleborus niger* and its varieties) continues well into January, and even later sometimes, and if a frame is set over them very good flowers for cutting will be obtained. These are succeeded in February and March by the Lenten Roses, which are principally varieties of *Helleborus viridis* and *H. orientalis*, delighting in a rich stiff loam in a shady position, and doing best if left undisturbed for years.

APRIL

is the month of bulbs, Wallflowers, and the various forms of Primula, a largely increasing class, some of the larger members of which, such as *P. elatior gigantea* (Cowslips) and *P. japonica* (which latter in deep, moist, rich loam grows 2 feet high) make very good specimens for cutting. The Leopard's Bane are very handsome, the best being *Doronicum plantagineum excelsum* (syn. *Harpur Crewe*), which grows some 3 feet or 4 feet high, producing long yellow Daisy-like flowers with a good length of stalk for cutting. They last a long time in water if picked soon after they are open. If they are mixed with some of the gorgeous scarlet Anemones, with Solomon's Seal (*Polygonatum multiflorum*) for greenery, a very effective arrangement is produced. Another beautiful combination possible at this season of the year is Leopard's Bane and *Dielytra spectabilis* (said to be more correctly called *Dicentra spectabilis*), the beautiful foliage of the latter, and its drooping coral flowers like bellows or lyres (hence one of its names, the Lyre flower), harmonising most delightfully with the starry yellow Leopard's Bane.

MAY

is the month of the late bulbs, tall Tulips, *Narcissus poeticus*, &c., with many beautiful Anemones, Ranunculus, and Lilies of the Valley, all of which lend themselves to table decoration more or less effectively, though each needs the particular sort of receptacle and method of arrangement best suited to it. The old-fashioned, short-spurred Columbines, both double and single, are very useful, their sprays of pendulous blossoms being very graceful, and they are not likely to be entirely neglected for the long-spurred varieties, beautiful though the latter are, by the lovers of old-world flowers, for are they not the real "gentle Columbine?" *Dielytra spectabilis* lasts in full beauty all through this month if not in too hot a place, and is very useful for mixing with many things. Another old-fashioned flower, the London Pride (*Saxifraga umbrosa*) should not be forgotten. It will grow in any wet sunless place, and its delicate panicles are useful for mixing with other flowers. In

JUNE,

the month of Roses in a normal season, though not in 1902 and 1903, as witness the summer shows of the Royal Horticultural Society at Holland House, the wealth of summer flowers begins, and for this and the two or three following months only a few of the best subjects for cutting can be given. Nothing is lovelier than a large bowl of Pæonies cut with long stalks so that they carry their own foliage. They need a large heavy vase or bowl, and a bold, free method of arrangement. Notwithstanding all the numerous and beautiful varieties now grown, the old crimson is still not to be despised. Of the Flea-banes the best is *Erigeron speciosus superbus*, a handsome border plant between 2 feet and 3 feet high, which is covered with large, lilac-purple, Aster-like flowers with orange centres. All these Daisy-like flowers are well adapted for decoration. Some of the loveliest flowers of the month are the long-spurred Columbines, which are hybrids obtained chiefly from crosses between *Aquilegia chrysantha* (Golden Columbine) and *A. cerulea*.

(Rocky Mountain Columbine). They are almost as remarkable in shape as an Orchid. Many were astonished at one of the fortnightly shows of the Royal Horticultural Society last summer to see a group of about fifty named varieties. They are not so hardy as the old-fashioned Columbines, and need a somewhat light soil, or one which is made so by the addition of leaf-mould. The Pyrethrums, principally hybrids from *Pyrethrum roseum*, must not be omitted, as their long stems and long duration render them very valuable for cutting. Some of the more recent introductions, both single and double, provide a wealth of colour. Some of the finest are James Kelway, brilliant scarlet-crimson; Vésuve, blood red; and Mary Anderson, flesh colour, all single. Aphrodite, pure white; Florentine, bluish white; Alfred Kelway, rich crimson; and Sam Bunburgh, white, one of the finest for cutting, all double. In a slug-infested garden it is difficult to keep Pyrethrums from destruction during the winter and early spring. The same remark applies to Delphiniums, which are at their best at the same time. Some think that the great rigid spikes are not adapted for cutting. Certainly some of the hybrids are ill-adapted for table decoration except on a very large scale, but some of the species, notably *D. hybridum* Belladonna, which only

hybrida grandiflora. The bright crimson centres of this variety make it very effective when mixed with Sunflowers, with *Gypsophila paniculata* for greenery. This last named has only come into vogue during the last few years and is now everywhere, and is quite indispensable for table decoration. It likes a calcareous soil, as its name implies, and therefore if the soil is not rich in chalk, some of this substance, or lime or mortar rubbish, should be mixed with the soil before planting. ALGER PETTS.

(To be continued.)

TULIP SIR THOMAS LIPTON.

Those who anticipate planting Tulips for spring blooming would do well to mark out this meritorious variety. It is a most brilliant satiny scarlet sort, and when planted in beds is more lasting than that popular variety Kaiser's Kroon, but not quite so large. It was the most striking variety we had, eliciting remarks from the most casual observer.

Talgarn, South Wales.

B. B.

DIANTHUS PLUMARIUS.

Of all the members of this valuable genus the common or feathered wild Pink may be said to be one of, if not the most variable in the size and

many forms is *D. p.* var. *serotinus*, with deeply fringed flowers, having a large brownish red zone near the base of the petals, which vary in colour from white to light purple. Other forms are numerous, and from this species have been derived the well-known and popular single and double varieties which are so much valued for decorative purposes in the garden and form one of the most favourite classes of florist's flowers we have.

W. I.

ROUND ABOUT A GARDEN.

PLANT POLITICS.

WHAT fine imperial instincts some plants seem to have! Every owner of a garden knows scores of plants which, in spite of their beauty, have made him sometimes regret their introduction into his borders, owing to the impossibility of making them respect their neighbours' territory. They come up "all over the place" in various unexpected ways, and scramble over every weaker plant, or grow up round it in suffocatingly close ranks of sturdy shoots, or send out great spreading tufts of leaves which flop down in autumn and smother all the small plants within reach. If we had party politics in the garden these plants would be the "Jingoes," and a Radical horticulturist might find the greater pleasure in a field day among them with a hoe.

THE WEAKNESS OF PLAIN-DWELLERS.

But, viewing the matter with that dispassionate serenity which a delightful autumn morning in the garden induces, we can see how the imperial spirit has of necessity become ingrained in some races of plants—as of men—whose history has been a hard and stormy struggle for existence. You do not find a spreading rampaging plant growing naturally in the open plain where sunlight is free to all. There each plant has been content to grow on its own spot of soil, doing its duty in producing flowers and seed. It is not from the soft, contented tillers of the rich Bengal plains that we get the splendid soldiers of our Indian Army. They have no fighting spirit who have been able to live in neighbourly fashion together for ages upon the produce of their land. For the purposes of good administration—and every garden is a sort of administration—these plain-dwellers should make the best subjects; but they are so seldom worthy of it, for the truth seems to be that the very hardships which make fighters of plants and men often endow them with the finest attributes.

DROUGHT-RESISTING PLANTS.

And one of the great pleasures in a garden or among wild plants consists in trying to trace back to its origin, in the stress and struggle for existence, of each of the qualities which make up the characters of the plants of to-day. Thus, in the succulent or fleshy plant, we see one whose ancestors for ages could only survive by retaining as much moisture as their tissues could hold, either because their lines were cast in torrid lands, with long intervals between falls of rain, or because they lived in sandy soil whose moisture quickly drained away. In such places the only herbaceous

THE FEATHERED WILD PINK (*DIANTHUS PLUMARIUS*).

grows 2 feet to 3 feet as a rule, though I have heard of it growing 6 feet. It is of a branching habit, and has very loose spikes of most beautiful Cambridge blue flowers. Unfortunately, it is a great favourite with slugs.

JULY AND AUGUST

offer perhaps the greatest variety of hardy perennials of any month of the year. The Sunflowers are a very numerous section, and some are quite indispensable. One of the best is the old *Helianthus multiflorus*, 4 feet to 5 feet high, with broad ray florets, and very free flowering. An improvement upon this, as regards flowers only, is *H. multiflorus maximus*, 6 feet to 8 feet high, the ray florets bearing a greater proportion to the size of the disc. Another species, perhaps still better, is *H. laetifolius* Miss Melish, about 6 feet high, producing a great abundance of deep yellow flowers on long rigid stems. *H. rigidum*, known also as *Harpalum rigidum*, has during recent years become the most common of all. One of the most valuable flowers for cutting, lasting in bloom as it does from June to October, is the *Gaillardia*

form of its flowers. It so readily crosses with its nearest allies that from one packet of seed flowers ranging in diameter from half an inch to nearly 2 inches may often be obtained; therefore to keep any particular form true it is necessary to propagate by layers or cuttings. This species differs from the wild Carnation in that the flowers are somewhat smaller, while the petals have their margins more deeply cut or fringed; it is also much hardier, and, although it naturally prefers and is more at home on old walls and in the rock garden, it is quite amenable to cultivation in beds and borders, where it will succeed and flower freely without any more attention than is usually bestowed upon many hardy perennials. Seedlings raised in heat in March and pricked off when large enough to handle are ready to plant out in the border in August. By the time they come into flower—the following spring—they will have formed good-sized tufts of glaucous foliage and will produce an abundance of flowers. A native of Central and Southern Europe, this plant is naturalised on old walls in parts of this country, and is well adapted for this purpose. One of the most distinct of the

plants naturally existing to-day are descendants of a long line of ancestors, who, as the centuries passed, acquired more and more of the power of storing moisture against the day of drought.

ALPINE METHODS.

So in alpine plants, which form a dense low mat of growth spreading outwards from the centre, we see the perfected habit by which their ancestors, while keeping close to the ground so as to offer little for the mountain winds to seize, managed to shade the spot in which each grew with a dense coverlet against the blistering sun, and at the same time to hold as much as possible of the rain. Many of them, too, have the power of rooting from their branches wherever these rest upon suitable soil; and, though this makes them unduly aggressive in a flower-bed or rockery, one can see how it was forced upon plants which had to feel their way, as it were, from crevice to crevice among the rocks.

HISTORIES IN LEAVES.

When, again, a plant has foliage of that cool grey-green which botanists call glaucous you may almost be sure that its ancestors grew within reach of the salt foam of the sea, and were compelled to acquire an armour-coated skin against it. Similarly all thorny plants tell us that their ancestors grew in exposed places where animals grazed or browsed, while plants evolved amid great severities of climate carry the proofs of it in very downy leaves. But, perhaps, of all plants those which most clearly show the influence of past ages are the creeping and climbing plants, each admirably adapted in its way to get outside the shade of overhanging foliage. None of them are plants which can survive in the open, where they are liable to be browsed or trampled by animals, and most of them are disseminated by birds or beasts which carry their fruits into the trees and drop the seeds there. In such cases the seedling is always confronted by the necessity of reaching the distant outer sunlight somehow, and, according as each species has learned to attain this end by ascending the trees or creeping along the ground towards the light, it is classed as a climber or a creeper, though

there are many which are equally adroit in both capacities. And such gifts, with their accompaniment of ceaseless movement and tendrils which literally feel all round for something to catch hold of, are none the less wonderful when we see how simply they have been developed by natural stages from the common gift of all vegetable growth to turn towards the light, and how this in turn is simply the natural result of the working of an universal law.

By no means the least interesting are those

always those whose ancestors have been forced to retain a place in the sunlight against the encroaching shade of greater growths above them. Had they been completely overshadowed they might have become weak creepers and climbers, or even parasites; but, planting themselves always boldly upon the outskirts of the forest growth, and moving always forward as it advanced behind, they have acquired qualities which make them, perhaps, the best fighters in the vegetable world. And so, when in autumn one discovers that this or that uncontrollable clump has fairly smothered some foreign weakling which we had hoped to cherish, a touch of fellow feeling may prevent us from rooting the whole thing up and flinging it on the rubbish heap.

E. K. R.

CORDYLIN INDIVISA VERA.

THIS magnificent plant is seldom met with in gardens in this country. It is a native of New Zealand, and from my experience of it here during the last few winters I think it will prove hardy in many parts of the British Isles if it is placed in a position sheltered from the wind, which spoils the leaves by splitting the ends of them. An excess of moisture at the roots during the winter is fatal to it, therefore it should have a well-drained soil, composed of leaf-soil, peat, loam, and sand. The plant photographed has seventy-four fully developed leaves, each on an average 4 feet 6 inches long and 6 inches wide. The colour is pale green, with a deep orange midrib and veins. The plants in the gardens here were raised from seed imported from New Zealand some years ago, and I am informed on good authority that no plants have been grown in Europe since

Messrs. Lee of Hammersmith raised some in 1840 or thereabouts. It is such a noble plant that it is a pity it is not more common. It has stood out here during the last four winters, and is not injured by ordinary frosts, but in a very severe one we cover it with a couple of bass mats, so as to be on the safe side until we succeed in getting up a stock of it.

J. RYAN.

The Gardens, Castlewellsan, County Down.

DRACÆNA INDIVISA VERA AT CASTLEWELLAN. (From a photograph sent by the Earl Annesley.)

plants whose imperial instincts seem to have a British character, since they send out colonies as offsets from the parent stem, and establish flourishing communities of themselves among all their weaker neighbours, eventually crowding these out altogether; for that which has always tempted the Britisher to take root in new countries has been the feeling of being cramped and overshadowed at home, and the plants which follow the same habit are almost

THE FRUIT GARDEN.

NEW CRABS AND THEIR VALUE IN THE GARDEN.

ON the 20th ult. the fruit committee of the Royal Horticultural Society had some interesting exhibits before them, no less than three distinct new varieties of Crab Apples being staged, and two obtained an award of merit. The Crabs are most useful for garden decoration, and I think in the desire to have showy plants of late years the Crab has been neglected. Of course, as a fruit it takes a second place, but even then such fruits as some of these trees produce have their value, as they make excellent jam and may be used in other ways in a cooked state. For some years I have advocated in *THE GARDEN* the culture of *Pyrus Malus* for its beautiful flowers alone in the month of May; they are very beautiful. Last season I was charmed by seeing in several old gardens a good number of the older varieties—the Siberian and the Dartmouth—planted in groups. Many might grow the Crab in small gardens, as when spurred back annually they make very pretty bushes or pyramids. Of course, this mode of culture is very artificial, but it is surprising what a wealth of bloom the trees produce when grown in this way, and they fruit grandly, rarely failing to produce even when grown in poor soils. I think this should not be lost sight of, as in some places the Crab in its various forms could with advantage be grown. They are most effective when grown as single specimens on grass. At Syon we have John Downie Crab in this position, and the trees are very fine with festoons of richly-coloured fruits in autumn. The trees are then shapely and more interesting than when grown in crowded shrubberies. *P. Malus floribunda* is a splendid lawn tree. The foliage of this variety is now changing colour. There are two forms. The older form is very pretty, whereas the new one is a large-fruited kind. The leaves in the autumn are quite yellow, and in the distance resemble a *Liburnum* in blossom. To describe some of the best of the older forms of these interesting trees would take up too much space, and I will briefly note the value of the newer forms.

I have referred to the Dartmouth, one of the best for cropping and richly-coloured fruits. This and the John Downie should be in all collections. Many varieties hold the fruits till frost, so that makes them more valuable. A very beautiful crimson Crab introduced by Messrs. Cheal—Cheal's Crimson Siberian—is most effective, and a good companion to John Downie and Dartmouth. The newer Transparent is a pretty yellow fruit and not unlike the older Siberian Yellow, but it has larger and bolder foliage. There is a new weeping variety—the Elise Rathke; if grown as a standard it is most effective. Another form, the new American Oblong, is a light yellow fruit striped with crimson and carmine; a very striking variety.

The new kinds given awards at Westminster were notable for their good eating qualities. One, Frettingham Victoria, a round, bright crimson fruit, should be valuable for making jelly. The new Veitch's Scarlet is unusually large; this was obtained by crossing the Red Siberian with Apple King of the Pippins. Last season Messrs. Veitch sent out a new Crab, Mrs. John Seden; this was the result of crossing Transcendent with King of the Pippins. Evidently the last-named is a favourite sort to work upon, and gives splendid results. The variety Mrs. John Seden is quite a new type; the fruits are large and more resemble the parent Apple. The colour is a light orange, spotted with crimson, flesh firm and crisp, with a pleasant acid flavour. This variety is well worth growing for its fruits alone. G. WYTHES.

RASPBERRIES AND STRAWBERRIES IN AUTUMN.

(Continued from page 229.)

STRAWBERRIES.

THESE resolve themselves under three heads for autumnal supplies, each distinct in itself, viz.:

1. The Alpine or Quatre Saisons of the French.
2. The so-called perpetual-fruited varieties, of which St. Joseph may be taken as the type.
3. The plants that have been forced in the spring, from which a secondary crop may be obtained.

1. The Alpine Strawberry has been catalogued for very many years in almost every nurseryman's list, being offered as runners. This is a great mistake, and as such should be erased from all catalogues. Owing to this system of cultivation from runners it is no wonder that these Strawberries have never become popular, or even satisfactory under good culture.

When raised, however, annually from seed success may be assured, even under moderate conditions. The difference between seedlings and runners is most marked, both in vigour of growth and fertility. Our plan is to sow the seed every spring from the middle of March to the middle of April. This is done in shallow boxes, 1 foot by 2 feet, rather than in pots or pans; hence the seed is not sown so thickly, whilst moisture is retained for a greater length of time. The soil used should be light and friable, say leaf-soil and sandy loam in equal proportions. A house or pit where the temperature can be kept at from 55° to 65° will be a good place for raising the seedlings. When these are large enough to handle and have made a fair amount of roots they should be pricked off. For this we use boxes of the same size as for the seed, putting about fifty young plants in each box. At this distance apart they do not become drawn up or weakly, whilst with each plant when next transferred to a border outside a good ball can be secured. The pricking off should be finished in May, the plants being then kept in a cool frame for a time until established and growing freely. Then, if the room be wanted, they can be stood outside. Later on—say, during July—the stock is again moved, being this time transferred to a partially shaded border (ours faces the east). Here they are put out with as much soil as possible at about 6 inches apart, so that a small hoe can be worked between them. Here they remain until October, when as a plot of ground becomes vacant they are planted out in their fruiting quarters.

Meanwhile, all that need be done is to keep the ground well stirred and any young runners removed, paying attention to the watering during hot weather as may be needed. The ground selected should be well trenched, being manured according to its needs. We use farmyard manure and lime. Light soil is preferable to a close retentive soil for the Alpine Strawberry, whilst if somewhat shaded it is just as suitable for the well-being of the plants. The ground should be set out for the rows at 18 inches apart, then plant three rows and miss one; thus a 3-foot space is left between each bed of three rows. If the ground be limited, some space might be spared by planting four rows instead of three and then miss one row. Plant firmly and water afterwards. If slugs or worms are troublesome, an occasional light dusting with lime will serve a good purpose. During frost the plants may be somewhat loosened; should that occur they should be made firm again when a thaw has taken place. Besides keeping the ground well stirred upon favourable occasions, no other attention will be needed until the first flower-spikes and then the runners appear. These should all be removed up to the first week in July, after which about half only should be taken off ten days later on, so as to give a succession. These seedling plants will under this treatment give a good succession of fine fruits and in quantities from the end of August well on into October, or for nearly two months. This plantation will commence to fruit in the regular season the following year, ripening about the same time as Royal Sovereign, but continuing until the next set of young plants are again in bearing. Thus Alpine Strawberries may be had without any difficulty whatever from about June 20 until the third week in October, or over a period of about four months.

Varieties.—The best to grow of the Alpine Strawberries are Rouge Amélioré, or Improved Red, which produces elongated fruits of a bright colour; Sutton's Improved Red, which is somewhat similar and of robust growth; Belle de

Meaux, which has darker coloured and rotund fruits; and the Improved White, which should be grown for the sake of its colour. All are equally fruitful and also of high flavour. In gathering the fruits we pick straight away into small fancy baskets, which then go upon the table as they are; or, if for travelling, into small square baskets or punnets, which are then packed into boxes. When picking for the former purpose no stems are taken with them. No plants are fruited after the second year's crop is taken. We grow about 1,000 from seed every year.—J. HUDSON in the *Journal of the Royal Horticultural Society*. Reprinted by permission.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

PROPAGATION OF HERBACEOUS PÆONIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In the very interesting paragraph on the propagation of herbaceous Pæonies, supplied by "G. B. M." to your issue of the 17th ult., there are one or two points upon which I hope he will help me. (1) To cover with 8 inches of light soil, does he raise a pyramid of soil over the stool? (2) Will the resting buds, to be looked for in September next, be *under* the surface of this pyramid? (3) Is it the old soil of the pyramid that is to be cleared away, or must soil in use before the pyramid was erected be removed also? H. K. M.

[(1) A pyramid of soil would throw off rains; a plateau would be better. (2) Yes, the resting buds of Pæonies (*P. chinensis*, the florist's Pæony) are formed just below the surface of the soil; smaller buds form on the stool itself, but the uppermost buds are the strongest. (3) The soil that is placed over the stools is to be cleared away after the young plants are severed. The original soil need not be disturbed; merely loosened to admit of the young plants being severed with their roots intact. Strou double Pæonies will often form three or four resting buds on one rooting axis. These may be removed individually with a portion of the stem and its roots attached, potted, and grown on in a little warmth till planting time to encourage further root action.—G. B. M.]

MIGNONETTE MILES'S HYBRID SPIRAL.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I was glad to see that Mr. Crook had a good word for this Mignonette. For years I grew standard and bush-trained specimens. The former used to produce from 200 to 300 spikes, many of them 15 inches long, and they were very sweet. In growth I found this variety was all that could be desired, being amenable to close pinching and training as a standard. Machet and some other huge-spiked varieties are all very well when grown as market plants in 4½-inch pots, but as specimens they can never be popular, as they do not make sufficient growth. E. M.

SALVIA HORMINUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This Sage is not often seen in gardens, a matter that is difficult to account for seeing that it has much to recommend it, not the least being its unusual colour, and one found in but few plants. Other recommendations are its free growth and that it can be raised from seed in spring. Last year, when visiting Melbury Park, I was charmed with its fine colour in a bed, and also with *Salvia patens*, that made a lovely show with its bright blue flowers. I obtained seed and sowed it in the spring in pots, growing the seedlings in a frame. This we used near dwarf yellow Marigolds, red and white *Phlox Drummondii*, and have given much

colour throughout the summer. It is not much affected by rain, and continues to flower right through the summer; it is excellent to cut from. With me in good soil it grows about 12 inches high. J. CROOK.

APPLE LADY SUDELEY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In your issue of the 3rd ult. (page 163) Mr. Field praises this variety for its free-bearing qualities. With me in the west it is just the opposite. I have a bush, twelve years old, on the broad-leaved Paradise stock, 9 feet high, in a most sheltered position. During this time it has not given us two pecks of fruit. On several occasions it has needed lifting and root-pruning. This has reduced vigour, but has not converted it into a free-bearing tree. We have it also growing as an orchard standard in a more exposed spot; here it cannot be considered free-bearing, although it behaves better than in the bush form. Probably with Mr. Field the soil is drier; the air certainly is, as we are within ten miles of the sea as the crow flies. When living in West Norfolk I often found many plants thrive better there than here in the west. Most Pears here are far inferior in flavour to those grown in Norfolk. I have never had better flavoured Glou Morceau than used to grow on a bush tree in that county. In the west the excessive moisture may account for the behaviour of this Apple.

Chard.

J. CROOK.

CARNATION MISS AUDREY CAMPBELL.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The enclosed photograph shows a spray of this most valuable border Carnation gathered from a town garden. I know of no better yellow variety for a garden that is more or less surrounded by bricks and mortar. It is hardy, grows vigorously, and blooms freely.

Finchley.

T. B.

PENTSTEMON NEWBURY GEM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I completely endorse the remarks of your correspondent on page 218 in praise of this valuable plant for grouping, producing as it does erect yet graceful panicles of bright red flowers from mid-summer until late autumn. *P. barbatus* is another species of value for the mixed border. Unfortunately, its growth is rather straggling, although if allowed sufficient space the flower-stalks will be strong enough to carry the inflorescences of delicately coloured flowers without the addition of temporary supports, which are so undesirable in the garden. The florist's varieties of Pentstemon when grown for a similar purpose have a more telling effect by planting in groups of distinctive colours.

Roth Park.

H. R.

CURL IN POTATOES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I notice that Mr. E. Hobday, in his most interesting article on experimental work in the Potato field (page 194), refers to the now common disease amongst Potatoes known as curl in the leaf, and I venture to add a few remarks on the subject. I question whether Potato growers generally realise how seriously crops are affected by its presence. When we get a bad attack of the blight (*Phytophthora infestans*), such as we had last year, everybody is talking about it, and the evil visitation is generally deplored, but few people seem to attach much importance to the curl disease; and yet, if statistics could be given, it is an open question whether the latter trouble has not been responsible for a greater shortage amongst Potato crops during the past three or four years than even the dreaded blight.

Probably Mr. Henshaw, who manages the Potato experiments at Burgoyne's Farm, near Cambridge, is right in his contention that the curl disease is spread through want of care in selecting

sets for seed, but, unfortunately, it is difficult, if not impossible, to detect its presence at planting time, so that the ordinary grower is often the victim of circumstances. Mr. Hobday observes that more evidence of the curl could be seen in some plots of less robust varieties than the strongest growers, and this, I think, coincides with the experience of most people who have given any attention to the trouble.

I have been studying the peculiarities of the disease in question for several years, and the instances in which I have noticed it amongst vigorous-growing Potatoes, like *The Factor* and *Up-to-Date*, are small compared to the less vigorous varieties which I have seen affected. I am quite of Mr. Hobday's opinion that the sets for planting should be chosen from the most prolific roots when lifted and kept by themselves; but even if this is done there is no guarantee that curl will not assert itself the following season. In my own case I have been most careful in the selection of seed sets, and after taking them from the most healthy and vigorous plants have noticed curled leaves and spindling stems the following season. At the same time I am opposed to the method adopted by some growers in their ignorance, namely, that of saving the tubers found at the root of affected specimens for planting because they are not big enough for culinary use, and doubtless it is by such ignorant practices that many diseases are perpetuated.

So far as my experience goes, the curl trouble is more prevalent in the southern half of Great Britain than the northern portion, and last year, from a consignment of seed obtained direct from Scotland, there was an almost entire absence of the disease, while amongst the same varieties grown from home-saved seed in the south curl was very prevalent. Except that it is generally worse amongst medium than vigorous-growing sorts, I do not think that the curl disease is a respecter of varieties, and this year it has caused considerable disappointment amongst such high-class Potatoes as *Evergood* and *Sir John Llewelyn*. One peculiarity about it is that in most cases, when the leaves are curled and the stems are spindling, the old tuber is lifted from the ground at the end of the season apparently harder and firmer than it was when it was planted. In other words, diseased seed sets refuse to decay, but the difficulty is to know at planting time which are so.

In the case of growers of acres of Potatoes the difficulty is very real, but in garden culture, where there are facilities for setting up the tubers to sprout before being planted, it may, perhaps, be got over by discarding those which, after being exposed to the light for a reasonable time, remain dormant or only push weakly sprouts. If any such tubers are cut, it may be observed that the interior is dry and woody instead of being juicy as a properly preserved Potato should be. Last spring I had a quantity of seed Potatoes set up to sprout a little before being planted, and I took the trouble to pick out those which had refused to start and planted them by themselves. Without an exception the plants were affected with the curl, and I got nothing except the old tubers and

a few tiny little specimens that were adhering to the parents when they were lifted.

Cottagers and small growers who are obliged to depend largely on home-saved sets for planting have suffered considerably through the curl trouble, and by this method of propagation it has doubtless been spread; but it is now so general that even when purchasing tubers from the most reliable sources one has to take the chance of whether they will acquit themselves satisfactorily after being planted or not.

In concluding his remarks on page 194 Mr. Hobday comforts himself that the matter will no doubt receive proper attention, and I presume he means at the hands of the Potato-growing fraternity

CARNATION MISS AUDREY CAMPBELL.

in general. I hope this will be the case, but while the grass grows there is a possibility of the horse starving, and at the present rate of progress the curl disease will soon be a bigger bugbear to Potato growers than the common blight.

G. H. HOLLINGWORTH.

ANNUALS AS BEDDING PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—One of the prettiest gardens that I have seen for a long time was filled with annuals of various kinds. There was not a single plant of any of the so-called "bedders" in it. There were Balsams,

Asters of various kinds, fragrant Ten-week Stocks, dwarf and climbing Tropaeolums, Everlastings with their many curious tints, Grasses, and other things too numerous to mention. Roses here and there, with a few good hardy perennials, completed the display, which was very instructive, as it illustrated admirably the value of half-hardy annuals, and proved that a gay garden in summer is a possibility without the aid of those plants that are costly and troublesome to keep through the winter. The fact seems to be that the capabilities of annuals are known to very few flower lovers. The primary outlay is small, the culture is simple, and the results are out of proportion to the expense incurred. With the exception of the zonal Pelargonium, annuals equal bedding plants in brilliancy, whilst they exhibit greater delicacy of tint. The soft shades of colour of Ten-week Stocks are particularly pleasing, and in Drummond's Phlox we get great brilliancy as well as refinement of tint. Annuals are too often grown in a haphazard way. Sown thickly in pans, and left in them till the "bedders" are in place, they become drawn and spindly, and are then hastily consigned to positions that may want filling up. These are often in the impoverished soil in the foreground of shrubberies, where they cannot obtain a fair share of either moisture or nourishment. Asters with highly developed blooms, and Balsams 18 inches high, with proportional lateral development, cannot be grown in this way. It is only in deeply-stirred, well-manured ground that the true characters of the plants are displayed. To those who have hitherto grown annuals in a haphazard way, the sight of them in the grounds of some large English or Continental seed grower would be a surprise. Drummond's Phlox is a host in itself, and every bit of good culture bestowed on it has its reward. The true nature of it is too often suppressed by a meagre diet. It wants plenty of good rotten manure worked in the ground at planting time. Put this down to a depth of a foot and you will have no reason to discard this annual for its fugacious character. If there is a summer-blooming plant that needs generous treatment it is this one. If it does, in a dry time, show signs of exhaustion, give a top-dressing of some stimulant, and wash it well in and you will get a good display of bloom up to the advent of frost. Give annuals the same good culture as bedding plants; give them a place of honour instead of just using them as stopgaps, and you will have no cause to complain of their want of effectiveness. It should, moreover, always be borne in mind that the same good treatment that gives perfect flowers ensures their remaining in beauty for a considerable time.

French provincial gardens are, as a rule, not so well provided with glass houses as in this country. The pleasure grounds are, however, often of considerable extent, and it is surprising to see how well they look in summer, when, perhaps, the only means at command is one orangery and some frames. These latter, however, the French gardener always has plenty of, winter salads and Melons being classed among the indispensable requisites in a French household. Thus he has the best means of raising and bringing on sturdily any amount of Asters, Marigolds, Balsams, &c. The attention thus being more concentrated on this class of flower, most of the French growers of them take great interest in improving the standard of excellence. In looking through some country gardens the gardener will probably point out some particular strain of Aster, Balsam, &c., which he will tell you has been worked up to a high state of excellence by careful selection over a period of years. I have seen wonderfully fine strains of Asters in such places, and I never saw such good double and single Petunias as in French gardens. In conclusion, I would urge awarding to half-hardy annuals a more important position than they now occupy. Their beauty in the adornment of the summer garden is great, and the pleasure they confer is obtained for a slight outlay. J.

PROPAGATING AND PRUNING THE LOGANBERRY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I am much indebted to Mr. G. A. Knight for reminding me of my omission at page 112,

where I stated that the Loganberry should be propagated by suckers. I was writing more from a private grower's point of view, namely, one who only requires a few plants. In this case it was a good plan to get them by suckers. I am aware such a method as regards numbers would be useless, and at page 186 the information given will be valuable. At the same time I should have added that the plant roots readily when the shoots are layered from the parent plant. I have frequently seen shoots that have been left some time on the soil making roots freely. This shows how readily the plant can be propagated. My earlier note concerned more its culture in a private garden. We do not require such large quantities as in a nursery, and why I referred to propagation was that a friend of mine had a goodly number of plants that had evidently been raised from seed, as, though they made a most luxuriant growth, they bore very few fruits. These were small in comparison with the ordinary plants that were first sent out, so that to save time and prevent disappointment it is well to get plants by suckers as described at page 112, or by layers as Mr. G. A. Knight advises.

At page 186 "T. E." asks the best way to prune, and as the plants are evidently making such a splendid growth they have done well. Taking a great interest in these plants from the start, I am pleased to give our mode of pruning, which is very simple. I do not say it is the best way, but at any rate we have secured very fine crops of fruit. We treat the Loganberry in a similar way to the ordinary Raspberry. As soon as the last fruits are picked we then prune, entirely cutting out the old fruiting wood and placing the new wood in position. "T. E.'s" plants being grown on a fence, I would advise laying in the new wood nearly full length, as next season the plants will fruit the whole length if the wood is a good size. Any small spray or crowded wood at the base may be cut clean out. The chief points in culture are to grow sufficient good growths in the season to take the place of the old. There is no gain in crowding, so that it is well to cut out as the shoots get large those that are in the way or crowding others. Always reserve the strong ones for future cropping. If the plants are attached to stakes, three to five canes or growths should be kept shortened to 6 feet and grown like the Raspberry; if to a trellis, the shoots should be longer and more may be left to a stool. G. WYTHES.

PHYGELIUS CAPENSIS IN THE NORTH.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It is interesting and useful to compare notes upon this valuable autumn-flowering plant with "S. W. F.," whose note in THE GARDEN of the 1st inst. I have read with pleasure. Its value as an autumn plant is undeniable, and even with us in Scotland it frequently flowers until December if the weather is at all mild. There are, however, some parts further inland and in the north where it does not retain the shrubby habit it has here. I have it fully 6 feet high, and its growths remain practically unharmed by the cold. Even if the tender parts of the branches are destroyed in spring growths soon push from the main stem, and in autumn the Phygelius is as fine as ever. It does best with me on dry rockwork and against a low wall surmounted by a trellis, which breaks the full sweep of the severe north-west winds. It has a strong tendency to increase by sending up suckers. This is particularly noticeable on rockwork, and here I have occasionally to cut some of these away. It is easily raised from cuttings, for which purpose portions of well-ripened wood should be used and inserted in light soil in a pot in autumn. Some gardeners strike cuttings annually, as they consider they then get better spikes, but the resulting plants are naturally less effective than large old specimens left undisturbed for years. Probably the reason of its shy-blooming in some gardens is that it has too heavy a soil or too much moisture at the root. Where it is at its best here the soil is exceedingly dry in summer. I have just measured my best plant, and find that it is 6 feet 6 inches high, 4 feet from wall to front, and 7 feet

across, while there are ninety spikes of flower. Some of these are over, but others are fresh and in perfect condition. I know this plant in many parts of Scotland, and, as already remarked, it is hardy in most places, even high up on the hills, although there it may be cut to the ground.

Carsethorn, by Dumfries, N.B. S. ARNOTT.

GARDENING OF THE WEEK.

FLOWER GARDEN.

PLANTING SHRUBS AND TREES.

ALTHOUGH many hardy trees and shrubs may be successfully planted at almost any time during the next five months, providing the ground is not frozen, the best time for most trees and shrubs, and especially conifers, is from now to the latter end of next month. The earlier the work is done the better, for early planting means a longer period for the formation of fresh roots, which will materially assist the plant to withstand any severities of the coming winter. It is advisable to make all preparations at least a few days before the actual planting is done. The extent of these preparations is a matter to be individually determined. In making a new shrubbery it may or may not be necessary to drain the land. If the natural soil is of good quality and suitable for the class of shrubs it is intended to grow, no addition will be needed, and, on the other hand, a quantity of fresh soil may be required. If it is intended to fill up any blanks in an existing shrubbery, it is usually necessary to make a good-sized hole and entirely remove the soil, or, at the least, replace a considerable portion of it with fresh.

PLANTING.

All bruised roots should be cut back to the sound portion with a clean upward cut. Unless the roots and ball of soil are thoroughly moist, the whole should be immersed in water for a few minutes. Planting in a dry state is responsible for many apparently unaccountable failures. Once planted when dry, it will take a surprising amount of rain and waterings to render the ball moist again. As a rule it is best to plant on a slight mound to allow for settling. Where the ground is level it will be found that conifers will thrive best if kept raised. Unless the soil is of a very heavy nature it should be well rammed, and a good watering is usually advisable. If it is needed, fix a stout stake at once.

TRANSPLANTING.

This work should also be done as early in the autumn as possible. Before starting upon heavy subjects it is wise to see that all the gear to be used—ropes, levers, planks, &c.—are equal to the strain likely to be put upon them, or a regrettable accident may occur. In the shrubbery weeds are again growing fast. At this time of the year the weather does not allow much hoeing to be done. A good alternative is to skim off and invert, weeds and all, a thin slice of the surface.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

BEGONIA GLOIRE DE SCEAUX.

MORE than any plant of its class perhaps this is ornamental during winter. Growing the plants too robust is often the cause of their failing to flower satisfactorily. They should not have large pots and a rich soil, but when the plants are in flower a little liquid manure applied with care to their roots will prove beneficial. A high temperature is unnecessary, but exposure to light with air in moderation should be given.

BEGONIA CORALLINA.

If kept growing until the spring of next year this will produce flowers in abundance. The object should be to produce a firm, short-jointed growth, and the use of stimulants of any kind should during the winter months be avoided. The roots appear to like lumpy fibrous loam, peat, a little dried cow manure, and some sand.

CALADIUMS.

Sometimes these plants are kept growing a little too late in the season, the result being that the following year the bulbs fail to start again freely. Occasionally during the winter they die away through immaturity. Every variety should by this time be put away to rest. A temperature of 45° in a dry house will suit most of them, but *C. Argyrites*, which is somewhat tender, should be given a temperature of not less than 50°.

AMARYLLIS.

The weakening of these bulbs is often the result of continually hurrying them into flower. There is a proper season for them to flower, and they should not on any account be forced prematurely, and afterwards encouraged to make growth. The temperature in which they ought to be wintered should not fall lower than 48° to 50°, and should be perfectly dry. Here they will remain until they show flower, which under ordinary circumstances will be about February and later.

ERICA AND EPACRIS.

Although the last-named plant differs somewhat in appearance and is more robust than the *Erica*, the cultural conditions for both plants are identical. They must at all seasons be given plenty of light, with abundance of fresh air to check mildew, a disease to which *Erica* is more susceptible than *Epacris*. Discontinue syringing the plants as well as damping the stages on which they are placed, but on very bright days water may be sprinkled about the floor of the house. Give water judiciously. Although the careful use of guano water and Clay's Fertilizer may have a beneficial effect upon the earlier-flowering soft-wooded varieties, the use of stimulants in general should be discontinued.

LACRENALIAS.

Bulbs just commencing to grow should be given attention. In some cases it may be necessary to repot them, while in others a top-dressing of fresh soil will suffice. In any case they delight in a fresh rich soil. Until now they have occupied a position in the cold frame, but will require moving to a shelf that is near the glass, as they do best with abundance of light and air and a cool temperature. Do not apply stimulants until the plants are rooting well, and then with much care.

J. P. LEADBETTER.

The Gardens, Tranby Croft, Hull.

FRUIT GARDEN.

PINES.

PLANTS, the fruits of which are now developing, should have a night temperature of 70° to 75°, according as the nights are cold or mild, and a steady bottom-heat of 85° to 90°. Cover the pits at night with mats to save hard firing, as the latter reduces the moisture necessary for the plants. Cease syringing, but damp the surface of the beds, paths, &c. Watering must be carefully done, and strong applications of liquid manure must be avoided. A drier manure or weak applications of guano water are more suitable at this season.

SUCCESSION PINES.

The earliest successions will need a lower temperature and also less moisture. A night temperature of 55° to 60°, about 70° by day, and a bottom-heat of 70° to 75° are quite high enough at this season. Only sufficient water is required during the present month to keep the leaves from shrivelling. Admit a little air on all favourable occasions, closing the house not later than 2 p.m. Keep later plants in a moist atmosphere, with a steady bottom-heat.

SUCKERS.

These will require more careful management as soon as they have filled their pots with roots. Arrange the plants so as to give them plenty of light and air, and see that they do not get too dry if plunged over hot-water pipes. A safe bottom-heat for these is 70° to 75°.

POT VINES.

If it is intended to force these early next month they should now be cut back and all lateral growths removed. The canes must be thoroughly ripened,

as it is no use attempting to force canes which are still growing. They should be kept rather dry; keep a little warmth in the pipes, with plenty of air.

GATHERING FRUIT.

It will now be necessary, owing to the succession of cold nights, to gather nearly all late varieties of Apples and Pears which are still hanging on the trees. Very late Pears which are in a sheltered position should be looked over, and those which are not matured allowed to hang a week or two longer if the weather remains favourable; the fruits will then keep better, and also be of better flavour. Any late varieties of Plums still hanging on the trees should now be gathered, and be either wrapped in tissue paper and placed in boxes, or laid thinly on the fruit room shelves, where they will keep in good condition for some time.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

CABBAGE.

INSPECT plots of recently put in plants, and make good any blanks from the seed-bed. See that the plants are made firm in the soil. If the first planting has made good progress they may be earthed up. Should this open weather continue another lot may be got in, choosing a sheltered position. These would be likely to come safely through a severe winter better than those that have made much growth. Inspect crops of winter Cabbages, Savoys, &c., removing all decaying leaves and pulling up large weeds. See that young plants in the seed-bed are not too thick, as they soon become drawn and useless.

BROCCOLI.

This vegetable has made extra strong growth in this district, and if not soon checked by frost they should be partially lifted. No lifting has been done in this garden for some seasons, and if the hardiest varieties are grown it is not often necessary. In cold gardens, however, it is wise to be on the safe side. When lifting just raise the plants sufficient to snap the strongest roots, then make the soil firm round the plants.

FRENCH BEANS.

These are now giving out, but the plants in frames may continue bearing for a short time. If it is still necessary to maintain the supply they must now be grown in heated houses. French Beans are not a profitable crop at this season of the year; from now on to the middle of January is the most critical time. A smaller-sized pot should be used during the next three months: a 6-inch pot will be ample. See that they are well drained. A compost may be made up of old Melon-bed soil, lightening it with some dung from an old Mushroom bed. Only half fill the pots, leaving this space for future top-dressings. Six or eight Beans may be sown in each pot, reducing the seedlings to five of the strongest. During the winter months, being weak in growth, they will be liable to attacks of red spider, and the plants must be syringed slightly at least twice a day, except when in bloom. Afford air when the weather is mild, and grow on as sturdy as possible.

CELERY AND LEEKS.

Another earthing should now be given to these, choosing a dry day for the work. Break up the soil finely with the spade, packing it round the plants with the hand. If extra large Leeks are required the feeding may still be carried on. Liquid manure from the farmyard will be most suitable, or fortnightly dressings of artificial manure. The latter should be well watered into the soil.

GLOBE ARTICHOKE.

These will require protection on the first appearance of frost. Light, rank manure may be placed round the crowns and well up the plants. Another plan is to place stakes to each plant and cover over with mats. Clear off all dead leaves and flower-stems. Remove suckers and pot them if this has not already been done.

*Hopetoun House Gardens,
South Queensferry, N.B.*

THOMAS HAY.

ORCHIDS.

WATERING.

CORRECT watering is of the utmost importance in the management of Orchids, although during late spring, summer, and early autumn a little indiscretion is not noticeable when the outside conditions are such as to cause quick evaporation. Now with shorter and less sunny days it is essential to guard against over-watering. The point to be observed is to maintain the plants in a sound, plump state with the least possible amount of direct watering. When rhizomes have been used for drainage and the compost used contains some leaf-soil much less water will be needed than if peat and moss and crocks were used. Again, it will be necessary to discriminate between plant and plant of the same variety. Those that have completed their growth and are not going to flower for some time require much less water than those that have not finished growing.

DAMPING.

I prefer using this means as far as possible to keep the plants plump. The amount of moisture necessary varies very considerably in houses, so it will be sufficient to say that humid conditions are essential whenever the temperature outside allows. During very cold weather I would rather forego damping and keep the houses dry and the temperature below the normal. Excessive firing is undoubtedly harmful, and the plants will winter far better if when the weather is bad these precautions are taken.

TEMPERATURES.

In giving temperatures for the coming months I will take the outside night temperature at 40°, morning at 56°. All the houses may be lowered 5°, and during hard frosts, if the plants and house are dry, 8°. On the other hand, when the outside temperature is higher, a rather higher temperature may be kept, providing a fair amount of fresh air is admitted through the bottom ventilators. Stove Orchid house, night, 70°; morning, 68°, rising with sun-heat to 90°, without sun to 75°. Cattleya house, night, 65°; morning, 62°, rising with sun-heat to 85°, without sun to 70°. Intermediate house, night, 62°; morning, 59°, with sun-heat to 85°, without sun to 68°. Odontoglossum house, night, 58°; morning, 55°, rising with sun-heat to 75°, without to 60°. Except in very bad weather keep some bottom air on all houses and a liberal amount on the Odontoglossum house.

Gatton Park Gardens, Reigate.

RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for October contains portraits of

Lonicera Etrusca var. *superba*—Native of the Mediterranean region. This is also known under the following synonyms: *L. etrusca*, *L. gigantea*, *L. Charlotti*, *Caprifolium periclymenum*, *C. etruscum*, and *C. dimorphum*. This is a handsome Honeysuckle, and apparently free blooming when grown under glass, as in the North American section of the Temperate house at Kew, but in the open air, though perfectly hardy, it will not bloom at all.

Mucuna sempervirens.—Native of China. This is a curious but not very beautiful trailer with large pendulous branches of purplish black flowers. The seed-pods and other parts of the plant are clothed with stinging hairs, which give it the local name of Cowhage or Cow-itch. It flowered for the first time in 1903 in the Temperate house at Kew.

Loropetalum chinense.—Native of India and China. This is also known as *Hamamelis chioensis*. It is a curious hardy shrub, whose flowers consist of bunches of narrow pure white filaments resembling those of the *Chionanthus* or Fringe Tree. It bears mild forcing quite well, and flowers freely in small pots, when it is very ornamental. It was well shown recently at one of the Royal Horticultural Society's fortnightly shows by Messrs. Veitch.

Zygocolar Veitchii.—Native of Brazil. This plant is also known as *Zygopetalum Veitchii* and *Zygolax Veitchii*. This is a rather handsome Orchid, producing spikes of large flowers, the upper petals of which are green, thickly spotted with brown, while the large lip is white, deeply veined with purple. It is of hybrid origin, being the result of a cross between *Colax Jugosus* and *Zygopetalum crinitum* effected by Mr. Seden.

Jasminum primulinum.—Native of Western China. This is an extremely handsome and free-blooming evergreen Jasmine, with large, bright golden yellow flowers, some of which are semi-double. It is one of the many fine plants sent to Messrs. Veitch by their collector, Mr. Wilson. It is believed never to bear fruit or seed, but propagates with great facility by suckers, and can also be easily increased by cuttings, which strike very quickly. It is thought to be an improved form of *J. nudiflorum*, which under different climatic conditions has become evergreen and has had its flowers greatly increased in size. It also does well as a pot plant, and is altogether a great acquisition.

The October number of *Revue de l'Horticulture Belge* gives a double plate of *Hemeranthus Lesourawacii*, which seems to be by no means a first-class variety of these generally bright-coloured and handsome bulbous plants or at all equal to several well-known varieties already in commerce, such as *H. Catherine* and others. The number of flowers on the head seems to be small, and the colour a dull brick red. W. E. GUMBLETON.

Besides the varieties described, the firm have also numerous trials of all the leading varieties suitable for garden cultivation, and from experience gained in this manner have decided to eliminate from their catalogue many of the older varieties which are superseded by their betters.

WINTER CUCUMBERS.

It is now too late to sow seeds, but there is yet time to put out strong plants for affording a winter supply of fruits. The Cucumber requires different treatment in the winter from the summer, for during that period the plants are less vigorous, and, consequently, require to be more carefully treated. In winter considerably restrict its rooting space. To this end it is advisable to plant in hillocks of compost—loam and leaf-soil—upon a stage over hot-water pipes, and periodically add thin layers of fresh compost; this is better than planting in larger beds of soil. It is important to attend to watering, and in so doing to see that the hillocks of compost are moistened throughout so that the base does not get dry. It is also

THE INDOOR GARDEN.

A NEW IMPATIENS FROM UGANDA.

IMPATIENS OLIVIERI was introduced from Uganda last year. It will, no doubt, soon be largely grown, as it is of vigorous habit and flowers freely. Plants flowered at Kew for the first time in July, 1903. These were raised from seeds collected along the Uganda Railway by Sir John Kirk. He found it growing in clumps at an elevation of 6,800 feet, about 300 miles up country on volcanic rocks. It grows about 4 feet high, and, as can be seen by the illustration, branches freely from the base. The leaves vary in size from 4 inches to 8 inches in length and 1½ inches to 2 inches across; they are, as will be seen, arranged in whorls. In its native habitat the flower is little more than 1½ inches across, under culti-

THE KITCHEN GARDEN.

POTATO TRIALS IN SCOTLAND.

PROBLEMS and possibilities of Potato development as they present themselves at the present time were explained the other day by Mr. W. P. Laird, of the firm of Messrs. Laird and Sinclair, at Monifieth Nursery. On the occasion several farmers in the district attended. The firm has been giving the important subject of Potato raising much consideration for the past year or two, and have now growing in their grounds a considerable breadth of the tuber. Included among those they have growing are Findlay's Eldorado, described as "one of the most prolific and best disease-resisting varieties"; Findlay's Northern Star Selected, a promising Potato; and a very fine break of Kerr's Duchess of Cornwall, a variety which stands in the front rank to-day, and a very heavy cropper. The crop should lift at the rate of at least 20 tons per acre, and these were grown from sprouts.

Sutton's Discovery was shown in good form, and is growing very vigorously. Factor is also a Potato which the party thought a lot of. King Edward VII. is doing very well at Monifieth, although they came irregularly, as all English seed did this spring, but they have filled up wonderfully. Goodfellow, another of Findlay's, sent out in 1901, develops into a very handsome tuber, and is a good cropper. Vermont Gold Coin, an enormous cropper, was lifted on September 14. Four pounds of this Potato, bought in May, were propagated by removing the sprouts and growing on, and planted out in the beginning of June. The crop lifted turned out to be over 10cwt. This, calculated out, is at the rate of 280 tons produce from one ton of seed.

During the tour of inspection various sets were lifted and weighed. Of Northern Star two were dug up in different places on the ground. The first had 33 tubers, weighing 7lb., and the second 25 tubers, weighing 7lb. One set of Duchess of Cornwall lifted had 14 marketable Potatoes, and weighed 5½lb. The Factor had 6lb. to a shaw of beautiful oval-shaped tubers. Sutton's Discovery, the great disease-resisting variety, had 12 tubers to the shaw lifted. One shaw of King Edward VII. had 31 tubers. The Eldorados, being in full growth, the party would not allow Mr. Laird to lift, but were satisfied as to their enormous cropping powers by what was exposed after the removal of a portion of the soil round an average set.

necessary to preserve a moist atmosphere, and daily syringe the foliage, especially upon its under surface, for a dry atmosphere encourages attacks of thrip. Regulating, thinning, and stopping shoots needs almost daily attention, while it is important to remove superfluous flowers and fruit early. Over-cropping is a mistake at all seasons, and especially so in winter.

The chief point in the culture of winter Cucumbers is to keep the plants vigorous. One of the principal aids to this end is a suitable glass structure heated with hot-water pipes to maintain the desired temperature without unduly heating them. It should also be light and provided with trellises, so that the plants trained upon them are kept near the glass. The greatest difficulty is to have a good supply of fruit when the days are shortest, but once this is past the growths quickly strengthen and yield fruit freely. With reference to varieties suitable for this purpose, it may be said that any free-fruited kind that is possessed of a good strong constitution will give satisfaction if properly grown.

T. COOMBER.

vation it is 2½ inches. Another curious point is the colour: in Uganda it is white, while at Kew it is pale lilac, with often a rosy tint. Had the plant been in cultivation for a few years this variation would have caused little comment, but occurring on plants raised from the seed collected in its native habitat the matter is interesting.

It is readily propagated by seeds or cuttings. The latter root readily at almost any time in a propagating frame. Insert singly in small pots, and shift on as required, using a moderately rich soil. It succeeds best in a fairly moist, cool greenhouse in summer; a dry, draughty house should be avoided. During winter an intermediate house is the most suitable. Coming from a high elevation and flowering freely, it will probably be useful for summer bedding. The illustration is of a plant eight months old, raised from a cutting. It is 3 feet 6 inches high and as many through. A. O.

KALOSANTHES (CRASSULA) COCCINEA.

THIS, one of the most brilliant and useful of all greenhouse subjects, is now less frequently met with than it was thirty years ago. In the records of shows held at Chiswick and Regent's Park we read of the grand specimens of Kalosanthes coccinea which appeared in the collections of Messrs. Fraser of Lea Bridge, and Mrs. Lawrence. Later still, Mr. John Ward of Leyton exhibited splendid specimens of both coccinea and Frederick Debois varieties, one plant of the latter grown by him being furnished with a hundred trusses of bloom.

Being a native of the Cape, the Kalosanthes enjoys abundance of light and sun-heat, and as it is of a succulent nature it requires special treatment in autumn in order to secure a thorough maturation of the wood, a condition absolutely necessary to ensure a display of bloom. If small plants having each several strong shoots can be procured, they should have their points pinched out towards the end of February. To facilitate new growth, several pairs of leaves should be carefully removed from the tips of each shoot, and in a fortnight or three weeks new branches will appear. If these leaves are not removed the plants break slowly and often very irregularly. Nine-inch pots are the most suitable for the plants to be shifted into, these sufficing for the first summer, and perfect drainage is essential, as the plants require a good deal of water when in active growth. K. coccinea thrives well in a mixture of three parts rough peat and one of fibrous loam; to this may be added a liberal supply of bone-meal, road grit, and pieces of charcoal the size of horse beans. In potting, the soil should be firmly rammed and finally soaked with water to settle it round the ball. Potting completed, the plants should be placed in a light structure commanding a night temperature of 50°, rising to 75° or 80° with sun-heat, keeping them near the roof glass and supplying plenty of atmospheric moisture throughout the day. When once new growth is produced freely, abundance of air by day and a little by night must be admitted. At the beginning of May the plants may be assisted occasionally with weak liquid manure, and a slight shade in the middle of the day in bright weather will save the fleshy leaves from sunstroke. In July, if the nights are mild and dewy, the plants will be improved by being placed out of doors in a sheltered position, first securing the shoots to neat sticks. In August the plants, having made as much growth as can be ripened that season, may be stood at the bottom of a south wall to induce perfect and early maturity. In rainy weather the pots must be laid on their sides. If, however, plants of exhibition size are required, they must not be allowed to produce bloom till the third year from the above-named potting, all shoots being again pinched for new growths the following spring. For wintering the plants no place is better than a cool, dry pit from which frost can be excluded, and where they can be fully exposed by day when the weather is mild even in midwinter.

J.

SOCIETIES.

THE NATIONAL POTATO SOCIETY'S SHOW.

THE first exhibition of the National Potato Society was held at the Crystal Palace on Tuesday and Wednesday last, and proved a great success, thanks in a large measure to the exhibits from trade growers, which formed the most important feature. The competitive classes were not in all cases keenly contested—in a few there were no entries at all—but some of them were of much value and interest, especially those designed to show which variety yielded the best returns from a certain number of tubers planted; to determine the value of varieties when cooked; and to bring forward the best new seedling Potatoes. Particulars of these and the other classes will be found below. Mr. Walter P. Wright, who, together with his colleagues, has worked hard for the success of the National Potato Society, well deserved the congratulations given by various speakers at the luncheon.

COMPETITIVE EXHIBITS.

TRADE GROWERS ONLY.

Some excellent tubers were shown in the class for twelve varieties, distinct, one dish of each. Mr. Walter Ness, King's Kettle, N.B., was first. Among his best were The

Crofter, Up-to-Date, Northern Star, Evergood, and White Beauty. Mr. J. W. Christie, Scotshaig Mains, Tayport, N.B., was second; and Mr. H. Scott, Boreham Road Nurseries, Warminster, was third. There was one more exhibit in this class.

There were no exhibits in the classes for six dishes of white rounds, six dishes of coloured rounds, six dishes of white kidneys, and six dishes of coloured kidneys.

AMATEURS.

For twelve varieties, distinct, one dish of each, Mr. B. Ashton, Lathom House Gardens, Ormskirk, was first. Some of his tubers were very large, although most were of first-rate quality, e.g., Reading Russet, Sutton's Standard, Carter's Snowball, Sutton's Satisfaction, and Sutton's Discovery. Mr. S. Cole, Althorp Park Gardens, was second with very good clean tubers; third, Mr. E. S. Wiles, The Rookery Gardens, Downe, Kent. There was one more entry.

Eight varieties, distinct: First, Mr. E. S. Wiles, The Rookery Gardens, Downe, Kent, with medium-sized tubers of Royal Sovereign, King Edward VII., Edgecote Purple, Lord Tennyson, and Pioneer; second, Mr. John Weathers, Pymmes Park, Edmonton. We could find no third prize award.

Three dishes of white rounds: First, Mr. F. G. Crampton, Gate House, Sissinghurst. The varieties shown were Charles Fidler, Snowball, and Up-to-Date; Mr. S. Cole, Althorp Park Gardens, was second; and Mr. B. Ashton, Ormskirk, third. There were two more entries.

There were no exhibits in the class for three dishes of coloured rounds.

For three dishes of white kidneys, Mr. E. D. Packman, The Library, St. Mary Cray, was first. He showed The Factor, Improved Kidney, and Up-to-Date; Mr. Crampton was second with smaller but excellent tubers, and Mr. B. Ashton was third. Two more entries.

Mr. Ashton was the only exhibitor in the class for three dishes of coloured kidneys, and was awarded first prize for good clean tubers of Mr. Bresse, King Edward VII., and Kerr's Leda.

COTTAGERS.

There were some very good tubers in these classes, although some of them were not quite as clean as they might have been. The chief prizewinners were Mr. S. Brodgate, Saltwood, Hythe; Eccles Gardening Society (Mr. N. W. Gray); Larkfield Gardening Society (Mr. H. Roots); and Mr. A. Hogarth, New Smallholm, N.E.

OPEN.

A very interesting class was that for "total yield of any variety from twelve consecutive roots, to be lifted under the supervision of the committee, or of a nominee of the committee, and sealed." The first prize (a cup, value two guineas, given by the Crystal Palace Company) was awarded to the variety Duchess of Cornwall, shown by Mr. H. A. Howes, Horncastle, the total yield from the twelve roots being 76½ lb.

For the best collection of seedling Potatoes not in commerce, a silver medal was given. This was awarded to Mr. John W. Boyce, Welney, Wisbech, who had some excellent tubers of Goldfinger, late, medium size, white round; Maxim, first early, medium size, white kidney; Peckover, large late, white kidney.

The best single dish of cooked Potatoes was judged to be Factor, sent by Mr. E. D. Packman, The Library, St. Mary Cray; the second prize was won by Snowdrop, shown by Mr. E. S. Wiles, Downe, Kent. Mr. J. M. Christie showed a variety called Food of the Gods, but evidently the judges did not think it so, for they gave it third prize.

SINGLE DISHES.

The best dish of Charles Fidler was shown by Mr. J. Boyce, Welney, Wisbech; of Discovery, Mr. S. Cole, Althorp Park Gardens, showed the finest tubers. This was a popular class, no less than seven dishes being shown.

Duchess of Cornwall: Mr. S. W. Miller was first for this sort; he showed very large tubers. Five dishes of this Potato were shown.

There were four dishes of Daniels' Duke of York, the first prize being won by Mr. B. Ashton, Lathom Gardens, Ormskirk. The class for Findlay's Eldorado brought five dishes, the best being from Mr. T. Stewart, Armfield, King's Kettle, N.B.

The coloured kidney, King Edward VII., was well shown, Mr. Ness, King's Kettle, File, having the best.

Findlay's Northern Star provided the most popular class; thirteen dishes of it were shown. The best were from Mr. T. Stewart, King's Kettle, N.B.; Mr. J. Brown, Arbroath, N.E., was second; and Mr. W. Ness, File, third. Thus all the prize-winners came from Scotland.

Sir John Llewelyn is an excellent Potato, and several exhibits competed in the class for it. Mr. B. Ashton, Ormskirk, was first out of six exhibitors. Mr. Ashton also had the finest tubers of Snowball, one of the best Potatoes.

The finest tubers of The Factor were shown by Mr. S. Cole, Althorp Park Gardens, Northampton. Seven others competed.

In the class restricted to societies affiliated to the National Potato Society the Larkfield Gardening Society had the best eight dishes of Potatoes, one of each kind. Among them were Up-to-Date, The Factor, Sir Walter Raleigh, and American Rose. Apparently the Eccles Gardening Society would have been first, but they were disqualified through showing duplicates. The Yalding Gardening Society were second.

THE BEST DISHES.

Prizes were offered for the best dish of tubers in each section.

Trade.

Best white round.—White Beauty. Shown by Mr. Walter Ness, King's Kettle, N.B.

Best coloured round.—Purple Perfection. Also from Mr. Ness.

Best coloured kidney.—Blue Beauty. From Mr. James M. Christie, Scotshaig Mains, Tayport, N.B.

Best white kidney.—Duchess of Cornwall. From Messrs. D. MacNeish and Sons, Arran, N.B.

Amateurs.

Best coloured round.—Reading Russet. From Mr. B. Ashton, Lathom House Gardens, Ormskirk.

Best white round.—Snowball. From Mr. F. G. Crampton, Gate House, Sissinghurst.

Best white kidney.—Duchess of Buccleuch. From Mr. S. Cole, Althorp Park Gardens, Northampton.

Best coloured kidney.—Kerr's Leda. From Mr. B. Ashton, Lathom House Gardens, Ormskirk.

NON-COMPETITIVE EXHIBITS.

The Llewelyn Cup (value ten guineas), offered for the best exhibit of Potatoes in the show, was awarded to Messrs. Sutton and Sons, Reading, who sent up a very comprehensive and attractive exhibit. Undoubtedly the most valuable and interesting part of this exhibit was a collection of pedigree Potato seedlings (disease-resisting) from crosses made in June and July, 1903. Each group of tubers is the produce of a separate seed sown in the spring of 1904. The plants have all been grown under ordinary cultivation in their Reading trial grounds. The roots were lifted on the 7th inst., in the presence of members of the committee of the National Potato Society. Many of the roots averaged over fifty tubers each, and in one case over eighty tubers were found. Such productiveness in the case of first year seedlings is probably without precedent. Messrs. Sutton's latest introduction, the well-known and much-talked-of Sutton's Discovery, was finely represented also. The remainder of this exhibit consisted of over 150 different varieties of Potatoes, including the leading sorts of the present day.

Messrs. Dobbie and Co., Rothsay, had a very fine exhibit of Potatoes. There were 100 dishes, each dish averaging fifty tubers. The baskets and dishes were arranged on a sloping background, thus resulting in a much more effective display. Seeds and seed-pods of the Potato were very interesting as shown here. Large gold medal.

Messrs. Bakers, Wolverhampton, exhibited 100 varieties, representing almost 6,000 tubers, a wonderful display. All were arranged in baskets. Needless to say, the best varieties were shown. Gold medal.

Hobbies, Limited, arranged a good display of Potatoes, with which were exhibited Chrysanthemums, Dahlias, and Roses in variety. Among the Potatoes was a new seedling John Austen (Early Puritao × Ringleader). All the best varieties were included in this exhibit. Gold medal.

Mr. S. M. Thompson, Potato agent, Edinburgh, showed some of the famous Dalmeny seed Potatoes, as Acme, Evergood, Radium, &c.

Mr. T. H. Scarlett, Market Street, Edinburgh, showed some new varieties, as well as many of those that have become famous.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, showed a collection of ninety-six dishes of Potatoes in eighty-five varieties, making a striking display. All the high-priced sorts were among them. Two new ones were Southern Cross (white kidney) and Garner's Seedling (white kidney). Silver-gilt medal.

Messrs. Cannell and Sons, Swanley, Kent, exhibited a collection of Potatoes of the leading varieties, as well as some fine Ailsa Craig Onions. Silver medal.

Messrs. Cross and Son, Wisbech, showed many of the best varieties, as Lim Gray, Northern Star, Radium, &c. Mr. Cross also showed many seedlings of his own raising, some fifty sorts altogether, as well as a root of Northern Star of some eighty tubers.

Messrs. W. Dennis and Sons, Kirton, Lincs, had a large exhibit of Potatoes, among which The Crofter was very prominent. The Recorder (estimated to yield thirteen tons per acre), Northern Star, Eldorado, Royal Kidney, Evergood, King Edward, and others were shown. Silver medal.

Messrs. W. W. Johnson and Sons, Limited, Boston, had a very good exhibit of Potatoes of the best sorts, The Diamond being prominent. Silver medal.

Mr. J. F. Williamson, Mallow, County Cork, Ireland, had a splendid lot of Duchess of Cornwall, one of the very best varieties. Mr. Williamson has prepared an interesting pamphlet giving the comparative yields of fifty-five varieties. Duchess of Cornwall comes out top with 37½ lb. from 1 lb. of seed. Northern Star only gave 31 lb. Silver medal.

Messrs. W. P. Laird and Sinclair, Dundee, exhibited a splendid lot of Scotch-grown Potatoes, and so did Mr. James Kerr, Dumfries. Messrs. Harrison and Sons, Leicester, were well represented by a collection of the best sorts.

In the exhibit from Messrs. George Massey and Sons, Spalding, the new Potato The Leader was very prominent. It is a large white kidney, and a big cropper. Many of the best sorts were shown by Mr. Massey.

Mr. W. J. Atkinson, Weston St. Mary, Spalding, exhibited the best Potatoes in quantity.

Messrs. Mackinder and Bennett, Spilsby, Lincs, showed Potato Sir John Franklin and others.

Mr. Findlay, Mairland, Auchtermuchty, N.B., exhibited specimens of his seedlings, e.g., Million Maker, Diamond Reef, Evergood, Up-to-Date, Eldorado, Northern Star, and other famous sorts.

Messrs. Cannell and Sons, Eynsford, Kent, showed a collection of Apoles, many of them beautifully coloured.

Mr. David Russell, The Essex Nurseries, Brentwood exhibited hardy shrubs.

Messrs. John Peed and Son, West Norwood, S.E., exhibited a good table of fruit.

Messrs. W. Colchester and Co., Ipswich, exhibited fertilisers, Ichthemic Guano, &c.

Other growers whose exhibits of Potatoes, although very good, we have not space to describe, were Messrs. Anderson, Coupar Angus, N.B.; Thomas Benson, Barnston, Birkenhead; J. Bettinson, Outwell, Ipswich; J. T. Blaydes, Epworth, Doncaster; Thomas Bradley, Peterborough; W. Coleman, Culverden Down, Tunbridge Wells; Henry Drake, Wisbech; O. W. D'Alcorn, Spalding; W. Davie and Co., Haddington; George Derne, Wimbeldon; James Gardner, Perth; R. W. Green, Wisbech; H. J. Hudson, Barnsley.

J. Illman, Lincoln; Importers Company, Limited, London, S.E.; Kelvins, Edinburgh; King and Co., Coggeshall; A. Lighton, Kirtou; W. L. Malden, Ham, Surrey; Main and Co., Edinburgh; A. W. Pepper, Downham; J. Poat and Son, York; H. Scott, Westminster, and others.

In the afternoon a conference was held on "Seed Selection and Storage," Mr. Findlay and Mr. Redington opening the discussion. In the evening "The Organisation of the National Potato Society" was the subject, introduced by Mr. W. P. Wright. Mr. A. D. Hall presided on both occasions.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE early exhibition of this society was held on the 5th and 6th inst. at the Crystal Palace, and there was a good display, although the early-flowering or garden varieties of the Chrysanthemum did not predominate.

OPEN CLASSES.

The best twenty-four blooms of Japanese varieties were shown by Mr. W. Ring, gardener to J. Warren, Esq., Chapel House Gardens, Waltham Cross. The flowers were all good. Some of the best were Bronze Soleil d'Octobre, Mafeking Hero, Mrs. J. C. Neville, Mrs. H. Emmerton, and Marquis Venusta. The second prize was won by Mr. James Brookes, Totteridge Park Gardens, Herts. Mr. C. J. Ellis, Warren House Gardens, Stanmore, was third. There were two more entries.

Mr. W. Ring was first for twelve blooms of Japanese, Marquis Venusta again being very fine. This is a large flower, with broad, drooping, silvery florets, with red reverse. Second, Mr. James Brookes; third, Mr. Henry Perkins, Greenlands Gardens, Henley-on-Thames. There was one more entry.

For six Japanese blooms Mr. A. C. Horton, gardener to H. H. Platten, Esq., Urmister, Essex, was first with excellent blooms of Mrs. W. Popham, Mrs. G. Mileham, Edith Shrimpton, Marquis Venusta, Lily Mountford, and Mrs. T. W. Pickett; second, Mr. George Kelsey, Riddings Court Gardens, Caterham Valley; third, Messrs. Saltmarsh and Son, Chelmsford.

Mr. Eric F. Such showed the best twelve bunches of early-flowering Pompons. Among them were Strettheath, rosy purple; M. E. Lefort, yellow; Bronze Bride, and White Pet. Second, Mr. D. B. Crane, Highgate.

Mr. James Brookes, Totteridge Park Gardens, had the best two vases of twelve blooms each, and very handsome they were; second, Mr. John Fulford, Moor Hall Gardens, Cookham, Berks; third, Messrs. Saltmarsh and Son, Chelmsford.

Twelve bunches of early-flowering varieties, distinct: These made a delightful display, Mr. D. B. Crane, Highgate, winning the first prize with an excellent lot. Carrie, bright yellow; Robert Pemberton, rosy crimson; Mrs. C. H. Curtis, a crimson single; Rockett, bronze; Horace Martin, yellow; Kitty, lilac-pink; and Goacher's Crimson were all very good. The flowers were arranged loosely in vases, and were very attractive. Mr. Such, Maidenhead, was second. There were no more entries.

In the class for a dinner table decorated with Chrysanthemums, Miss Fairweather, Bifrons, Canterbury, was first. She used yellow and bronze varieties with good effect.

Miss Cole, Feltham, won the first prize for three epergnes of Chrysanthemums. She made use of yellow and bronze varieties.

Mr. A. Taylor, East Finchley, was given first prize for a bunch of yellow early-flowering Chrysanthemum Carrie. Prize given by Hobbies, Limited.

For six bunches of Chrysanthemums, distinct varieties, Mr. James Brookes, Totteridge Park Gardens, was first with lovely bunches of Horace Martin, yellow; Bobbie Burns, bronze; Mme. Marie Masse, Goacher's Crimson, and others. Mr. D. B. Crane was second.

Mr. E. F. Such, Maidenhead, was first for a bunch of white early-flowering decorative Chrysanthemums.

For a vase of five Japanese blooms Mr. C. Payne, Sandhills Gardens, Betchworth, was first with a very good lot of Merstham Yellow; second, Mr. H. Perkins, Henley-on-Thames, with the variety Hon. Mrs. Acland.

The first prize for a vase of early-flowering Pompons was won by Mr. James Brookes.

Mr. G. Kelsey, Riddings Court Gardens, was first for a vase of five blooms of any variety, except white or yellow, with excellent flowers of Mrs. G. Mileham.

For a vase of five white blooms Mr. Rayment, North Oxenden, was first with Miss Alice Byron.

AMATEURS.

Twelve blooms of Japanese varieties, distinct: First, Mr. M. Rayment, gardener to W. Beech, Esq., North Oxenden, Romford. Henry Perkins was a very fine bloom; it has long, thin, twisted florets of gold and bronze. Second, Mr. W. Trowell, gardener to D. Link, Esq., The Avenue, Beckenham.

Mr. D. B. Crane had the best twelve bunches of early-flowering Pompons, but even they made a poor show. Mr. A. Taylor, East Finchley, was second.

Miss Cole won the first prize for a basket of Chrysanthemums, with a pretty exhibit of yellow and bronze flowers and tinted foliage. Miss Cole was also first for a basket of garden flowers. Mr. Such, Maidenhead, had the best basket of Roses, and Miss Brewster showed the best basket of autumn foliage and berries. Mr. James Brookes, Totteridge Park Gardens, was first for one vase of Chrysanthemums.

TRADE EXHIBITS.

Messrs. Cannell and Sons, Swanley, showed a striking group of Cannas and Kochia scoparia, the plume-like foliage being a rich crimson (silver-gilt medal); Messrs. T. S. Ware, Limited, Feltham, exhibited a splendid lot of tuberous Begonias and other hardy flowers (gold medal); Mr. H. J. Jones, Lewisham, made a grand display with Michaelmas Daisies and Chrysanthemums (gold medal); Mr. E. F. Such showed Chrysanthemums, &c. (gold medal); Hobbies, Limited, Dereham, exhibited Dahlias in great variety and excellence (gold medal); Messrs. Cheal and Sons, Crawley,

showed hardy fruits as well as hardy flowers in great variety (silver-gilt medal); Mr. H. Berwick, Sidmouth, displayed an excellent lot of hardy fruit (gold medal); Messrs. Peed and Sons, West Norwood, also showed hardy fruit (silver-gilt medal); Mr. David Russell, the Essex Nurseries, Brentwood, sent shrubs (silver medal); Mr. A. L. Gwillim, New Eltham, Kent, sent tuberous Begonia blooms (silver-gilt medal); and Messrs. Champion and Co., 115, City Road, E.C., showed their handsomely finished tubs for shrubs.

FLORAL COMMITTEE.

The meeting of the floral committee at the Crystal Palace on the 5th inst. was one of the best attended of its kind for a long time. Mr. D. B. Crane was in the chair. A splendid array of novelties was submitted on this occasion, several receiving the coveted honour. The more conspicuous blooms were:

Miss Mona Davis.—This is a very large spreading exhibition Japanese bloom, having broad, reflexing florets, indented and slightly curling at the ends. The colour may be described as rich creamy-white, with a deeper centre. First-class certificate to Mr. Norman Davis, Framfield, Sussex.

Mrs. Lucie Dawson.—The committee had this variety submitted to them as one suitable for market or cut flowers, and in making their award of a first-class certificate it was so regarded. The flowers are of the purest white, and each is borne on a long stout, erect footstalk. The florets are of medium width and slightly incurve. Also from Mr. Davis.

Arthur Du Cros.—In this large Japanese flower we have a typical exhibition bloom. The florets are of medium width, neatly arranged and pleasingly drooping, making a flower of deep build and beautiful form. Colour deep rose, slightly suffused white, with a silvery reverse. First-class certificate to Mr. F. Bullimore, The Gardens, Canon's Park, Edgware.

Viola.—Large, deeply built exhibition Japanese bloom, having broad florets, incurving, reflexing, and curling rather tightly. Colour tinted rose on a silvery white ground. First-class certificate to Mr. M. Silsbury, Providence, Shanklin, Isle of Wight.

Winnie.—This is a pretty little early-flowering Japanese variety. A plant was submitted to the committee that had been partially disbudded, and the decorative value of the variety was quite apparent. The colour may be described as deep rich yellow, and the small reflexed-like blooms much resembled some of the larger hybrid Pompons. The plant was about 18 inches high. From Messrs. H. Cannell and Sons, Swanley. First-class certificate.

The committee wished to see again *Godthard Beauty*.—A large, rather flat flower, with medium florets; colour tinted and edged rose.

Sunshine.—A promising broad-petalled Japanese flower; colour orange-yellow, tinted and suffused crimson.

Mrs. Wm. Hubert.—Pretty decorative Japanese variety; colour deep flesh-pink with golden centre.

BOWDEN (ALTRINCHAM) AMATEUR HORTICULTURAL CLUB.

THE first autumn meeting of this recently-formed club of enthusiastic amateur gardeners was held in the Lecture Hall, Downs, Bowden Road, Altrincham, on Friday evening, the 30th ult., when a most interesting exhibition was got together. This embraced hardy flowers of all descriptions. The judging of the flowers is done in a most systematic manner by a scale of points. A recipient of full points gains a certificate of merit. This distinction fell to a lady; her display of flowers was set up with taste and skill, vases, bowls, &c., being used to exhibit the different flowers at their best. The members are encouraged to display their flowers artistically, and there were several instances in which this was most pronounced. Mr. D. E. Crane of Highgate, London, in the evening read a paper on "Early Outdoor Chrysanthemums." An appreciative audience listened for an hour and a half to the lecturer. Its culture was gone into very fully, so that the merest novice might, with a little careful thought, achieve success. Propagation by cuttings and division of old plants, treatment of young plants, summer treatment, preparation of beds and borders, staking and tying, aeration of the soil and watering, and many other points were dealt with in turn. The lecture concluded with a selection of twenty-five of the best Japanese and six of the most noteworthy Pompon sorts. Several questions were subsequently put to Mr. Crane, each of which was replied to. The president of the club (Mr. George Arthur Wright, F.R.C.S.), who occupied the chair, proposed a vote of thanks to the lecturer, which was enthusiastically carried. It was generally agreed that a most profitable and enjoyable meeting had characterised this first autumn gathering of the club. Mrs. Duggan, The Downs, Altrincham, Cheshire, is the honorary secretary.

EARLY-FLOWERING CHRYSANTHEMUMS AT TAMWORTH.

THE so-called Chrysanthemum "feast" at Tamworth is now regarded as an annual event. Through the enterprise of Mr. William Sydenham of Bolehall House, who provides the necessary prize money for the show and also bears all expenses, a pretty exhibition is got together and much useful information disseminated. Early varieties have been collected from all sources. This is the third year of the trial, and by a persistent weeding out of undesirable kinds and the proper naming of those retained, the plants are excellently arranged.

The collection is arranged in alphabetical order, and while this facilitates the inspection of the plants as a whole, the general effect is not so good as it might otherwise be. In the first place, the first series of plants under the letter A may not be more than 18 inches to 2 feet in height, while the second series under the same letter may be quite 4 feet high, and this fact is frequently to be seen, to the disadvantage of the smaller and dwafier plants. Again, by this alphabetical arrangement the period of flowering is also much mixed up. The present season may be regarded as a late one.

From what could be seen of the majority, the plants will be better about the second week in October. By that period there should be a perfect blaze of colour. The Japanese sorts largely predominate, but among the Pompon sorts there are many interesting and beautiful plants. It is difficult to understand why more of the better Pompons are not used in the garden. It is as garden plants that Mr. Sydenham is endeavouring to get the early-flowering Chrysanthemums recognised, and if he can only induce the garden-loving public to plant a few specimens as a trial, he is convinced that they will go on with them. In this view many competent authorities are agreed. Visitors come from all parts to see the trial and visit the show, growers from the north, south, east, and west of the country participating in the treat.

The more noteworthy Japanese sorts in the trial deserve special mention, and Goacher's Crimson may well lead the van. This is a large flower of a rich deep crimson colour, with a golden bronze reverse to the florets. Mme. Casimir Perier, a creamy white tinted pink kind, is a most profuse bloomer, and as a branching plant excellent. Mrs. A. Willis is a beautiful sport from the last-named, the colour of which may be described as yellow, shaded and striped red. In habit it is identical with the parent plant. Rosie is a lovely rich warm terra-cotta flower, borne on stiff, erect stems on a splendid habit of growth. This is a most effective kind, contrasting splendidly with the yellow sorts. Carrie is a gloriously rich yellow flower, blossoming freely and persistently also. It is a dwarf plant, too. Norbert Puyrez, an old plant of excellent quality and indispensable, develops lovely golden-salmon flowers quite freely. Its habit of growth is ideal; it is very dwarf also. The Grunerwalde family was in superb form. These plants are represented by M. Gustave Grunerwalde, soft pink, tinted white; Henri Yvon, rosy salmon on yellow ground; Mrs. E. Mollinson, yellow and bronze; and Louis Lemaire, yellow, shaded bronzy orange. In each case the flowers are large. The plants are not very strong in their habit of growth, yet they are highly valued; height about 18 inches. White sorts were represented by Mychett White, Market White, Doris Peto, Roi des Blancs, Parisiana, Cranford White, White Grunerwalde, Satisfaction, Mrs. Squires, and others. Jimmie is a grand crimson-purple sort, having large and handsome flowers. Kitty, on a later series of buds, has flowers of the loveliest shade of pink, and the members of the Masse family were all in good condition. Pompons were grand, especially Mr. Selly (peach-pink) and its apicose sport Mrs. E. Stacey, also J. B. Duvoir, pink; Mme. E. Lefort, orange and red; Little Bob, rich chestnut, White Lady, blush; Piercy's Seedling, bronze; and a host of other sorts. The event of the trial may be considered in every sense a distinct success and a credit to the originator. D. B. CRANE.

BOTLEY AND SOUTH HANTS.

THE eleventh annual show of the above society was held in the Market Hall, Botley, on the 21st ult. Unlike in many societies, certificates of merit are given according to quality of the exhibits. The County Council also offers money prizes for collections of vegetables in six varieties, also prizes for the pupils from the Hants County Council plots. Mr. G. King, the instructor of the pupils, is to be congratulated on the produce shown, so keen and numerous were the exhibitors, and the quality was excellent. The association each year distributes Potatoes of recent introduction to the members, offering prizes for the best dish. The variety chosen this year was King Edward VII., and brought forth sixty-one dishes—a really grand sight and a show in itself.

Groups were arranged down the centre of the hall. Lady Jenkyns (gardener, Mr. W. Davey) gained the premier award, employing very graceful plants of Palms, Crotons (finely coloured), Liliums, and other suitable plants, edged off with Panicle and Isolepis. The most noteworthy plants in this exhibit were Eucharis amazonica, carrying fourteen spikes of bloom, and said to be grown in a cold house during summer. Mrs. Maltby (gardener, Mr. J. Matthews) followed with a tasteful arrangement. Carnations, Streptocarpus, and Begonias were very good in this exhibit.

A collection of fifty varieties of Asters was shown by Mr. W. Linney. This exhibit was greatly admired. Perry's Pink, Sensation, Triumph, and Amellus were very showy. A first-class certificate of merit was awarded.

For a huge bank of fruit and vegetables, half consisting of fruit and half vegetables, Mrs. Maltby gained the coveted award with high-class produce very well arranged, the fruit being particularly fine. The vegetables were equally good. Onion Ailsa Craig (very fine), Carrots Sutton's Favourite (very good) and Intermediate, Cauliflowers Autumn Giant and Purify, Potatoes Toogood's Tremendous, Windsor Castle, and King Edward VII. were the best, Beetroot Sutton's Green Top (splendid), Parsnips Tender and True and Intermediate, Runner Beans Best of All and Prize-taker, Tomatoes (good) Princess of Wales and Perfection, Cucumbers, Leeks, Marrows, Turnips, and Celery finishing off this meritorious exhibit. Lady Jenkyns came next with a very fine collection. Potatoes, Beetroot Toogood's Black (very fine), and Brussels Sprouts were the chief dishes. A. E. Woodrow, Esq. (gardener, Mr. C. Chappell), E. H. Liddell, Esq., Kitkocks (gardener, Mr. W. Livermore), and others contributed capital collections.

For the best collection of Pears Mrs. D. Clark, Brixedone, Bursledon, was easily first. The same exhibitor also showed a very fine lot of the Dartmouth Crab.

Botley is no less famous for Potatoes than it is for fruit. For a collection of twelve dishes Mrs. Maltby was first. For ten varieties Mr. W. Davey led. Amateurs contributed some very interesting exhibits. Mr. W. Waller staged very fine Ailsa Craig Onions, Potatoes, and Parsnips.

Prizes offered by the County Council for six varieties of vegetables brought six entries, the first prize going to Mr. W. King for a very good collection; Celery Southampton Red, Cauliflower Purify, Carrot Favourite, Onion Ailsa Craig, Parsnip Toogood's Marrow, and Potato Up-to-Date were included in this set. Mr. Frank Emery was second, having good Cauliflower, Celery, and Potatoes; third, Mr. C. King.

THE GARDEN

No. 1718.—VOL. LXVI.

[OCTOBER 22, 1904.]

WALL GARDENING.

ALTHOUGH we well know that many alpine plants thrive much better on the almost perpendicular surfaces of rugged walls than they do in any other spots, wall gardening may be said to be almost in its infancy—in this country, at any rate. Nature, if allowed full play, will teach us many things we do not know, and we have only to visit an old-fashioned garden, where things are left pretty much to themselves, to realise the truth of this. Old crumbling walls have many times been a source of the greatest pleasure to us, and we have seen pretty little alpine plants, that have almost baffled us to get established on the ordinary rockwork, quite at home on such places. Besides alpine plants, these old walls give room to other things. It is no unusual sight to see old walls beautifully draped with the graceful Ivy-leaved Toadflax, Pansies, &c., while the top is gay with common Wallflowers, many other Cruciferae, *Linaria purpurea*, and suchlike plants. We believe, indeed, that many hundreds of alpine plants may be grown in this way finer than in any other, and they will survive our damp winters much better than on the rockery, where a large percentage is probably lost through over-abundant moisture. The difficulty will be, of course, in getting them properly established, and the most satisfactory way is by sowing the seeds at the proper time, and keeping them moist until they germinate. On a wall such as we have indicated we have seen the Cheddar Pink flowering more freely than we have ever known it to do on the rockery, and the same may be said about many alpine plants, such as *Erinus alpinus*, most of the crusted Saxifrages, and notably *S. longifolia*, the alpine Toadflax, the silvery-leaved *Potentilla*, and nearly all the Stonecrops and Houseleeks. The Cobweb Houseleek (*Sempervivum arachnoideum*) is very handsome in these positions. We are not, however, nearly at the end of our list, as it includes many of the Campanulas, as *C. garganica hirsuta* and *C. vericolor*, which grows in just such positions in sunny Italy. The Ligurian Hairbell (*C. isophylla* and *i. alba*) stands here, when it gets killed in the open border. It is one of the most profuse flowering species, and is not hurt by drought. *C. Raineri*, *fragilis*, and others are also suitable, and may be made quite at home. Almost all the *Dianthus*es of the plumarius type will be found suitable, the *Androsaces*, *Drabas*, *Hypericums*, *Epilobiums*, *Convolvulus*, *Antirrhinums*, and many other

equally handsome and desirable kinds. In many gardens walls have been built specially and properly for the reception of these plants, and where they have been made a part of the rockery, as we notice has been done at Kew, the convenience will be found very great. In building a wall as much care should be taken with regard to soil as there would be with a rock garden. Roots of many alpine plants travel a long way, and if the wall has been built against a bank of good soil the shady spots will be found most suitable for the various *Ramondias*, *Jankaea Heldreichii*, *Haberlea rhodopensis*, most of the choicer dwarf Ferns, alpine *Speedwells*, &c. Cacti, such as *Opuntia Rafinesquii*, *O. missouriensis*, and *O. humilis*, will form a very interesting group for a rock garden of this description. In places where the garden has been divided from the park by a sunk wall this with a little care may be made a highly interesting object. Indeed, all sunk walls where the sides may be built up of rough stones are capable of being made as beautiful and rich with alpine vegetation as a so-called rockery.

AUTUMN TINTS.

THE value in the park or garden of trees and shrubs, whose foliage fades in rich and glorious colouring, was opportunely emphasised by the exhibit from Captain Holford in the Royal Horticultural Hall last Tuesday. The beautiful tints of the Oaks, Acers, the Japanese Spindle Tree (*Euonymus alatus*), *Carya glabra*, and many others, of which cut branches were shown, bore eloquent testimony to their value in the garden landscape at this time of year.

There is a mystery about the autumn colouring of the foliage of hardy trees and shrubs in this country, and we have never yet ascertained with any degree of exactness the conditions that produce the richest and brightest colours. Probably the conditions most favourable generally are provided by a good growing season—that is, a warm, moist summer—followed by a dry, sunny autumn. But it frequently happens after what one would regard as favourable seasons, that species which are usually quite trustworthy in this matter fail to colour well. Probably one set of conditions does not suit all trees and shrubs in this respect. To produce the colouration of the leaf just before it falls certain subtle chemical changes in its composition take place. And to bring about these changes certain conditions in regard to sunlight, temperature, and moisture are necessary. But in a climate such as that of Britain, where the seasons are never alike two years together, we can never hope to obtain the same regu-

larity of autumnal colouring that characterises the vegetation, for instance, of the Eastern United States. Still, when all is said, we possess in our gardens a large number of trees and shrubs and climbers that are delightful in their autumnal livery of crimson, purple, scarlet, or gold. It is curious that every season we may notice species not usually conspicuous for their autumn tints beautifully coloured.

An over-vigorous, sappy growth, often the result of a wet, warm autumn, or too rich a soil, is certainly detrimental to autumn colouring. *Rhus cotinoides*, an American Sumach, worth growing for the beauty of its colours in autumn, is one of the most unfailing in this matter. But young plants, put out in well-trenched, heavily-manured soil, will often fail to colour at all till they get older and less vigorous. The most beautifully coloured examples of this Sumach that we have seen grow in rather light sandy soil. We have frequently noticed, too, that various species of Vine (*Vitis*) when starved in pots will colour exquisitely, whilst others, planted out in the ordinary way, completely fail. We believe, therefore, when planting with a view to the production of autumnal colour, any great enrichment of the soil is neither necessary nor advisable, provided it is of moderate quality to start with.

POTATOES TO EAT.

BY all accounts the National Potato Society seems to have had a most successful inaugural exhibition. At all events, a superabundance of large, handsome, and prolific tubers were on view, and the big Potatoes had every opportunity of mutual admiration and congratulation. There is, however, just one trifling deficiency in the exhibits and aims of the society, judging from its reports. It is nowhere stated that the intention is to produce edible Potatoes. By edible I mean suitable not only for the cattle yard, but, by way of concession, for the dinner table. I have read several reports of the late show with minute care, and, literally, the word *flavour* does not occur once. In one report of nearly 500 lines the only indication of the show being concerned with a human food product was a paragraph of five lines dismissing a class for cooked Potatoes without a word of comment on their quality. My own experience of the new and much-belauded varieties—the few which I have been foolish enough to encumber my garden with—is that each is inferior, if possible, to its predecessor. Up-to-Date, no longer of course a novelty, but filling field and market all over the country, is only fit for not very discriminating cattle. Sir John Llewelyn is rapid and tasteless, and it is impossible to understand how any private grower can waste ground over it while the Ashleaf kinds exist. Evergood

has never been good with me, and Northern Star is flavourless, does not resist disease, and is most annoying in its habit of super-tuberation.

A Lincolnshire grower, who has been concerned in the present Potato mania, admitted quite frankly, when I questioned him, that the consideration of flavour is not taken into account at all, that the dealers, indeed, in the Eldorados, &c., can obviously not afford to taste the taste and consistency may be like kitchen soap. The craze is a purely monetary gamble, and has as little to do with the quality of its material as a Stock Exchange gamble has to do with actual scrip and investment. We are really, in some respects, an extraordinarily stupid nation. Think of judging our fruits and vegetables, as we habitually do, by the eye and not by the mouth! A writer in *THE GARDEN* lately took great pains to apologise for the yellow colour of a certain Potato, and all the dealers' catalogues insist on the merit of whiteness of flesh. In point of fact all the really high flavoured Potatoes, beginning with the unapproachable Ashleaf, are yellow fleshed, and the whiter a Potato is the more it becomes a mere lump of tasteless starch.

In old days, when I was a good deal in France—I dare say we have perverted the French good sense by now—one never saw a white Potato put on the table, but always delicious yellow Potatoes, modest in size, of the Marjolin strain. I have one now, and have had it for over twenty years. We lift it before the Ashleaf, and it keeps until the end of the winter. I obtained it from the firm of Vilmorin-Andrieux. Longer ago than this a Guernsey friend sent me a basket of a small, roughly-shaped, red Potato, which was quite superb in flavour. This I lost by an accident in the vicissitudes of time. In my old countryside the cottagers grew some very ancient but most toothsome varieties. I particularly remember one called Norfolk Kidney, smooth and yellow. One may look in vain for such quality in the wonderful new show Potatoes. The decadence of the English vegetable began with the introduction of the American varieties, Early Rose, Beauty of Hebron, &c. These were all of the most wretchedly insipid quality, but took the market and the unthinking cottagers by reason of their productiveness.

Surely the aim of raisers should be the infusion of the Ashleaf quality into Potatoes which will crop well and keep through the year. The last production which to some extent fulfilled these conditions was Magnum Bonum, no later seedling that I have tasted has come near it in table quality. But it is sadly apparent that Potatoes are no longer raised with a view to their suitability to the saucepan, but, like the Jew's razors, are "made to sell."

G. H. ENGLEHEART.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

ROSE DOROTHY PERKINS.

From Bicton Mr. Mayne sends a few flowers of this delightful Rose, with the following note: "This is decidedly an acquisition among Roses. Its lovely bright pink flowers are borne in clusters, and are quite a feature in the garden even at this date, the middle of October. In fact, the plant is more full of bloom than it was earlier in the summer. We have it as a weeping standard, and it shows to great advantage in such a position. It should be a good variety for covering pergolas, sloping banks, trunks of trees, &c. It appears to do well in pots, as it has been shown in excellent condition at the Temple show towards the end of May. Cuttings of half-ripened wood inserted now under a west wall will stand a good chance of forming roots and be fit to transplant in twelve months. Crimson Rambler is carrying a good second crop of flowers, and the plants made excellent growth last summer. A great drawback to this variety is that it so soon mildews, and requires frequent syringing with an insecticide to keep it clean."

SWEET PEAS FROM A CUMBERLAND COTTAGE GARDEN.

Mr. Cuckney writes: "I am spending a few days in the Cumbrian Lake district, and sending you a few Sweet Pea flowers which I gathered yesterday in a cottager's garden. Generally speaking, in the south of England Sweet Peas have been long past. I know that they are by no means uncommon in the north-west of England, for I resided in this district nearly twenty years. My experience is that it is far easier to grow these and many other things in this equable climate than in Southern England, especially Kent, with its hot sun and scanty moisture, though Apples do not come into the category." A posy such as Mr. Cuckney, who is the well-known gardener at Cobham Hall, Gravesend, sends for our table is as welcome as the Roses of summer. The flowers were fresh and fragrant, and fortunate are those who can keep this winsome annual far into autumn.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

October 25.—Croydon Chrysanthemum Society's Show (two days).

October 27.—Exmouth Chrysanthemum Show.

November 1.—Burnmouth Chrysanthemum Show (two days); Brighton Chrysanthemum Show (two days); Royal Horticultural Society.

November 2.—National Chrysanthemum Society's Show at Crystal Palace (three days); Southampton Royal Horticultural Society's Show (two days); Highgate Chrysanthemum Show (three days); Lowestoft Chrysanthemum Show (two days); Portsmouth Chrysanthemum Show (three days).

November 3.—Weybridge Chrysanthemum Show; Colchester Chrysanthemum Show; Forest Gate Chrysanthemum Show (three days).

November 4.—Windsor and Eton Chrysanthemum Show; Battersea, Clapham, and Wandsworth Chrysanthemum Show (two days); Hinckley Chrysanthemum Show (two days).

November 5.—Batley and District Chrysanthemum Show; Loughborough Chrysanthemum Show; Penarth Chrysanthemum Show; North Lonsdale Chrysanthemum Show.

November 8.—Ipswich and East of England Horticultural Society's Show at Ipswich (two days); Dulwich Chrysanthemum Show (two days); Sevenoaks Chrysanthemum Show (two days).

November 9.—Buxton Chrysanthemum Show; Southend Chrysanthemum Show (two days); Stoke Newington Chrysanthemum Show (two days).

November 16.—Liverpool Horticultural Association Chrysanthemum and Fruit Show (two days).

November 17 and 18.—Grimsby Chrysanthemum and Fruit Society.

Royal Horticultural Society.—A general meeting of the Fellows was held on Tuesday last, when Dr. Maxwell Masters, F.R.S., occupied

the chair. Seventy-six new Fellows were elected, which makes a total of 1,256 fresh subscribers since January 1, 1904. Those elected included Lord Ernest S. Maur, Lady Montagu Bargovine, the Hon. Mrs. Bathurst, the Hon. Mrs. Brodrick, Sir Herbert Maxwell, Bart., Mrs. J. W. Lowther, Mrs. Ian Malcolm, Major A. B. Mayne, and Colonel H. D. Rooke. In introducing the Rev. Professor George Henslow, who had kindly consented to deliver a lecture on "Geographical Botany as a Result of Adaptation," Dr. Masters mentioned that the society were under a fresh obligation to the lecturer, who had just made valuable presents of books for the Lindley Library and for the Students' Library at the Wisley Gardens, and he hoped that many Fellows and others would follow Professor Henslow's example and present books to the library which, in the new building, would have more than double the space available. If each would thus do his share, the gaps and omissions in the library would soon be made good. In the course of his remarks, Professor Henslow referred to the prevailing habit of classifying plants "Tropical," "Asiatic," and other classes, whereas the same plants were frequently met with in different parts of the world, and varying localities and nature so changed their characteristics that those not learned in botany were wont to regard them as distinct species. He further showed the various metamorphoses which many plants experienced in such changed conditions as regards climate, exposed situation, altitude, soil, and the like. The lecture was very fully illustrated by a magnificent series of lantern slides, and by water-colour and other illustrations, all specially made for this lecture, and these served to enforce and prove each point dwelt upon by the Professor.

The Succulent house at Kew.—This is open again to the public after having been rebuilt. The collection is of great interest, and in the new quarters visitors anxious to study the plants are provided with greater facilities.

The Hon. Frances Wolseley's Garden School.—The Hon. Frances Wolseley writes from the Farm House, Glynde, Sussex, a letter describing the new garden school that has been recently established there: "The pupil receives practical instruction from the lady gardener in the following branches of flower gardening (no vegetables), with a view to her being able to undertake gardening as a profession. She will be taught the every day work of a garden, rolling, mowing, sweeping, and tidiness. Digging and manuring, seed sowing, planting and growing herbaceous plants, pruning Roses and fruit trees, laying out gardens, arranging flower borders, &c. She will be taught the management of greenhouse plants, watering and ventilation, forcing bulbs and plants for winter flowering, forcing Violets in cold frames, hotbeds, &c. The pupil can also learn flower market gardening for profit. She will be taught forethought, and in due course given a certain amount of responsibility, which will fit her eventually to manage a garden without help. The course of work is shortened or prolonged according to future requirements of the pupils, but should not be less than a year in order to obtain the experience derived from change of seasons. Half holiday once a week according to arrangement. Hours of work, as arranged by lady gardener, to be punctually observed by the pupil. The pupil pays a small entrance fee of £10 for one year, and £15 if she stays two years. It is paid in advance, and this fee will not be refunded unless the pupil leaves by Lady Wolseley's desire. In this case her money will be returned according to the length of time she has received instruction. The pupil is allowed one week's trial before paying entrance fee. She defrays all her own expenses for board and lodging. Lodgings can be obtained in the neighbourhood. Apply, Hon. F. Wolseley, Farm House, Glynde, near Lewes, Sussex." The head gardener is Miss Verrall, Gold Medallist of the Royal Horticultural Society, and preference in the choice of pupils is given to the daughters of professional men who intend to make gardening a profession; there are at present three vacancies in a comfortable cottage.

Phlox Helen Vacaresco.—Those who are in want of a good pure white-flowered herbaceous Phlox should grow the above. In height it reaches 2 feet, produces an immense panicle of pure white shapely flowers, and has deep green abundant leafage.—E. M.

Phlox Virgo Marie.—While we are all anxious to collect varieties of the herbaceous Phlox with extremely large blooms we are apt to pass over varieties most desirable in other respects. For instance, this older form is one of the finest late-flowered ones I know, giving huge panicles of pure white flowers long after the bulk of other sorts are over. It grows 4 feet high.—E. M.

Rudbeckia pinnata.—Among cone flowers this is a desirable variety seldom seen in an ordinary garden, but which in the middle of October is of much value. The plant grows 5 feet in height, and has deeply cut foliage. The flowers are produced on stiff erect stems, and are about 3 inches in diameter. The petals are 2 inches long and three-quarters of an inch wide, and droop quite close to the stems. The colour is pleasing, a deep lemon.—E. M.

Rudbeckia fulgida.—This cone flower appears to be little known to the ordinary cultivator, yet it is a most valuable sort, giving quantities of flower in October when the borders are getting dull. In height it grows from 5 feet to 6 feet, according to circumstances. The flowers are 2 inches in diameter, the ten petals are half an inch wide, overlapping each other, making a shapely flower of a deep yellow colour with a particularly dark disc. The habit of growth is erect, yet much branching. It is thoroughly hardy, and in every respect desirable.—E. M.

The Flame Flower.—It would be unfortunate if those who have not tried to establish that most brilliant of all hardy climbers, *Tropaeolum speciosum*, in England, were deterred because the late Dean Hole many years since professed his inability to get it to grow. It is possible that at a later date he met with success. In any case, there are to be found in England plenty of instances where the Flame Flower has become thoroughly established and does admirably. I have seen it thriving equally well on both warm and cold aspects. Several years since I saw it on a south aspect at Frensham Hall, Haslemere, growing so freely as to be in danger of becoming a weed. Mr. H. J. Veitch has it on a north aspect at East Burnham Park, Bucks; it flowers gloriously there in July. But it is found in all sorts of places and under diverse conditions. Let all who have gardens try to establish it.—A. D.

Southern seedling Potatoes.—That there is just now a rage for novelties in Potatoes there can be no doubt, and in certain directions that rage has been excited into a mania. Manias, however, are seldom of long duration, and usually are succeeded by periods of sanity and slump. But the raising of seedling Potatoes will still go on, as it has gone on quietly for the past forty years; it has been most effective in stemming the tide of disease which devastated our old varieties in years past. Messrs. Sutton and Sons of Reading have long been raisers of new varieties, and this year they have just lifted some 500 seedlings. From out of them fully fifty have been found to show high promise as croppers and disease resisters. It is doubtful whether seedlings anywhere excel these fine novelties. Many others of the batch would ten years ago have been regarded as wonders.—A. D.

Clematis montana var. rubens.—In the nursery of Messrs. James Veitch, Limited, at Coombe Wood I had the pleasure a few weeks ago of seeing a few blooms open on this plant, which is one of Messrs. Veitch's novelties, and although it was quite out of season, enough could be seen of it to form an opinion of its merits. In general appearance it is much like *C. montana*, but is darker coloured, the branches and leaf-stalks having a reddish tinge. The flowers, which are as large as the best-sized flowers of the type, are reddish or deep rose in colour, and will form a fine contrast to the ordinary white. Judging from the way it grows at Coombe Wood, it will be quite as easy to cultivate as *C. montana*, and from the

appearance of the wood it will be as free flowering. *C. montana* var. *rubens* was sent home by Messrs. Veitch's collector from the mountainous regions of Central China.—W. DALLIMORE.

Lotus pellioryhneus as a bedding plant.—A very attractive bed in Hyde Park is one filled with this plant. The slender shoots of grey-green leaves have trailed all over the bed and have quite covered the soil. Even now (October 10) it is very effective. As a foliage plant of quiet colouring, or as a suitable ground colour for brighter flowers, it seems especially suitable. As a flowering plant, of course, it is not of value for summer bedding. I have never before seen it grown for its foliage alone.—Y. Z.

Helianthus decapetalus.—Now there are so many forms of deep yellow, almost orange-coloured Sunflowers, it is pleasant to have a few plants of a lemon-yellow shade. Even for the attractive and uncommon colouring of the flowers this plant is worth growing. It is of easy culture and flowers freely, so that it can be confidently recommended. A group of it towards the back of the herbaceous border adds considerably to the beauty of the latter, and relieves the monotony of rich yellow so common among autumn flowers.—Y. Z.

Fritillaria aurea.—This is an Asia Minor plant, and one of the most fascinating of all

FRITILLARIA AUREA IN THE ALPINE HOUSE AT KEW.

Fritillarias. It grows but a few inches high, and bears a solitary, pendulous, balloon-shaped flower from 1 inch to 2 inches across, golden-yellow in colour, faintly netted on both surfaces with maroon tracery, but more heavily flecked maroon on the outside. The outer base of the flower is also flushed with the same colour. The bulbs are scarcely larger than a good-sized Pea, but they are wonderfully tenacious of life. This plant is seen to the best advantage when planted in breadths on gentle slopes or raised borders, sowing the bulbs broadcast as one would do Peas. The plant is very hardy, and the bulbs should not be lifted to store. They attain much greater size and flower in greater profusion when allowed to remain in the ground. It is also admirably adapted for pot culture, as may be seen from the illustration.—G. B. MALLETT.

The Celery maggot.—Never, I think, do I remember a season when Celery generally has suffered so much through attacks of the leaf-mining maggot; in many places the tops are little else but masses of browned leaves. It is well known, of course, that a fly originates the maggot which does the mischief, and the former must have been very plentiful this year. The worst of this pest is that

it has several broods in a season, and Celery is liable to be affected from the early summer till late in the autumn, though generally it is at the latter season that the most damage is done. There appears to be no magic way of dealing with the Celery maggot, and the old remedies of dusting the tops with soot or syringing them with soapsuds and quassia to make them distasteful to the fly appear to be the only means of checking it. As gardeners are always anxious to learn I should like to know whether any readers of *THE GARDEN* have a more efficacious way of dealing with Celery maggot.—G. H. H.

Hidalgoa Wercklei.—This climbing plant with Dahlia-like flowers has been spoken of as a very free-growing, profusely-blooming cool house climber, but that would not be my description of it. It grows freely enough; in fact, too soon becomes a dense thicket, but the flowers are very few and far between. It has a position within 2 feet of the glass roof, where, with proper attention to thinning and regulating the many thread-like shoots, it ought to flower much better than it does. When growing it requires almost daily attention, as the tendrils lay hold everywhere, hence, if neglected, a tangled mass is the result. It is often attacked by aphids under glass, worse even than *Solanum jasminoides*. It should only be planted where the structure can be frequently fumigated, and this prevents its being grown in conservatories adjoining the house. Perhaps some growers will give readers their experience of this plant as to its behaviour under glass.—J. MAYNE, Bilton.

SUGGESTIONS FOR THE GROUPING OF BULBS.

(Continued from page 254.)

OF course this system may be the only one we have to consider, or it may be only a part of a much larger "astronomical" scheme involving the planting of other kinds of bulbs in the adjoining grass. In the first case, there is only the allotted space to be covered with the best arrangement we can evolve, but if we have to go on extending our work a far greater amount of care and discrimination will be necessary. Are we to keep the different sorts separate, each in its own province, divided by wide intervals from its neighbours, or to mix them together more or less, or to allow them to blend gradually with, and overlap, each other? Probably we should decide on the last of the three plans, and I shall assume that it is so. The effective and natural blending of, say, Snowdrops with Cyclamens and Cyclamens with Narcissi (I am using these three kinds simply for the sake of illustration) may be rightly termed an art, though "the art itself is Nature"; it is so easy to overdo the thing, so hard to do enough to create a perfect harmony in the grouping and to carry the eye without effort from one system to the other. Let us assume that we have to deal with these three flowers then. We must be careful to plant some Snowdrops within the borders of the Cyclamen region, and some Cyclamens in the territory of the Snowdrop. Similarly, we must have a few Narcissi with the Cyclamens, and *vice versa*. And these "bond-stones" must not be confined to a few scattered monotonous singles on or near the boundary; there should be also an occasional group of several bulbs, and at rarer intervals a good-sized patch or clump of the one sort, intruding (perhaps a considerable distance) upon, and dove-tailing into, the others.

As already suggested, the various bulbs employed in such a plan should be treated with equal consideration as part of the whole, and the outlines of each group should be more or

less indicated before planting is commenced. The whole site will be an intricate forest of sticks or labels for a time, and visiting friends may perhaps make merry at our expense, but no matter! A thing well thought out is already half done, and we shall have reason to bless this same forest when we actually get to work, in spite of its involved and unsightly appearance.

Where there are trees, or shrubs, or permanent beds on the grass to be planted, it becomes somewhat easier to carry out our scheme, for the roots of the trees, or the undulations of the turf in their vicinity, the outlines of the shrubs and beds, give us something to start with, so that, with half-closed eyes and heads knowingly a little on one side, we are able to dip into futurity and form a notion of "what it will look like when in flower."

If the tree roots are large and well defined so much the better, and better still if they project boldly above the turf for a portion or portions of their length, for they at once indicate to us a line or directing axis for a constellation and its satellites. Can anything be more beautiful than a graceful setting of Snowdrops or Cyclamens around and along these roots, especially if they be gnarled and knotty and moss-grown, as we find them under Beech and Birch trees? Such roots within our garden precincts cry aloud for bulbs, for Scillas and Chionodoxas for Fritillaries and Snowdrops. But we must be just as careful, though happy in the possession of suitable trees and shrubs, to dispose our bulbs in a graceful and natural manner, as if we were planting an open, unoccupied piece of ground. There must be the right amount of nebulae, of constellations, and of single stars, and each system must blend, not clash, with the others. Even if we have only half-a-dozen of each kind of bulb it is possible, nay, imperative, to construct a natural group with these, a miniature universe of beauty. The two exquisite illustrations in Robinson's "English Flower Garden" of the Poet's Narcissus at Belmont, and Snowdrops at Straffan, should be carefully studied by all bulb planters before commencing work.

The above remarks will apply equally to any contemplated planting of bulbs on an extended scale in the rockery or bed; anywhere, perhaps, but in the formal long border. We must aim at the same grace and elegance as on the grass, and our colours must not have too harsh a dividing line. Take, for instance, a bank sloping from the rocky ledges above to a level space extending as far as the turf or path adjoining the rockery. We want a mass of bulbs here—Scillas and Daffodils, and, perhaps, Anemones and bulbous Irises. How are we to plant them? On the same system as that already sketched out, I venture to say, though we need not keep the various species quite so distinct and separate in this case. We should have our "nuclei" of each, and its ramifications and "out-liers," but we may mix our sorts with greater freedom and irregularity I think. We must not, that is to say, put all our Daffodils and Iris on the low ground, and all the others higher up, or *vice versa*; each kind should seem to have its headquarters when we look at them all in a mass, and there should be larger and smaller gatherings of each here and there among the scattered single bulbs; and if we employ the white form of a coloured flower let us be careful not to dot and group it too thickly among the type. One or two single white Scillas, for instance, and a solitary clump (not the circular one already alluded to) of the same, among the blue ones,

will add to the beauty of both forms, and of the planting as a whole.

I have tried, as far as possible, to "generalise" in these remarks, and have carefully abstained from any recommendations as to the most desirable and suitable bulbs to plant, for their name is legion, and all are beautiful and worth growing on grass or in the border and rockery. This is essentially a matter of individual taste and selection; nor have I gone into the question of the times of flowering of the bulbs to be planted, though this, of course, is a matter worthy of the most serious consideration if we are preparing for a delightful simultaneous display of flowers in our corner, and this is most probably what we have in our mind all the time.

We must choose those bulbs whose period of blooming in ordinary seasons most nearly coincides, plant them, and hope for the best. So much detailed information on this subject is now available in gardening books and notes that we can hardly go wrong. One caution I may be allowed to give, and that is, "Do not expect a successful and simultaneous result from the ordinary spring Crocuses, the yellow, white, and purple kinds." They may bloom all together the first season, but in after years there will be sad blanks at all times throughout the flowering season, at least that is my own experience.

One more suggestion and I have done. It is a most welcome fact that in order to remedy any shortcomings or mistakes in our planting of bulbs (at any rate, of nearly all of them), we can at any time after they have appeared above the surface of the ground, even when they are in full flower, lift carefully, and move them from one place to another without much risk of loss. So that we can gradually improve upon our system in the early spring-time, alter and shift our groups and "out-liers" about, till we can think of nothing more that can possibly be done to perfect our handiwork; then we can lay down our trowel, take off our gloves, give a sigh of content, and go indoors to tea.

S. G. REID.

COLOUR IN THE MIXED BORDER.—III.

I AM now going to treat of the latest phase—herbaceous border gardening. I allude to the scheme of planting out the ground in different sections of one decided colour or shades of one colour. I must tell you that this idea is extremely difficult to carry out effectively and practically for many reasons, and there is no doubt it will increase considerably the labour and cares of gardening. Still, everything that adds to the interest of the most charming and entralling of all occupations is well worth trying, and as this new departure appears to have met with much approval in the world of amateur gardeners it must be dealt with carefully and exhaustively. First of all, it seems to me that some technical knowledge of colours and their relative values would not only be useful as a means towards success, but absolutely necessary. I have seen one or two borders planted with no consideration of this important matter, and the result was far from satisfactory. Now the fact that we have a great quantity of flowers at our disposal, and that these are of many varying colours and tints, adds to our difficulty.

Let us suppose that our border is ready for our operations, and that the time has arrived to begin the arrangement of the plants. We will say that the border is 60 feet long and

6 feet or 7 feet wide. We must now decide on the extent of each section and divide the ground accordingly, marking out the division line with a spade; then, having done this, we must make some kind of colour plan. The simple or primary colours, as every school child knows, are blue, red or scarlet, and yellow. The secondary, or compound colours, are purple, composed of blue and red; orange, composed of red and yellow; and green, composed of blue and yellow. So the colours you will have to work with are blue, red or scarlet, yellow, purple, or mauve; you have also another compound colour—pink, and that is the most intractable colour of all, and is not supposed by science to be in true harmony with any other colour. But surely it is not a discord with blue: indeed, it is used by Nature constantly in exquisite combinations, and who can look at Apple blossoms against the blue of an April sky and not think it a perfect harmony? Of course, you do not reckon green, but you have white, which with black is called an extreme colour.

It is a good plan to take your paint-box and work out for yourself a little drawing of your border. One of the best gardeners I have ever known had a plan made of her garden, and in the spring she used to fill in the design with the colours she intended to use—for those were the days of the geometrical flower garden. Meantime, however, I will make some suggestions which you can take for what they are worth. When the primary colours—blue, red, and yellow—are combined they make a perfect harmony, but remember that if blue and red are placed next to each other the red must be scarlet. A splendid effect, for instance, may be obtained by planting a large group of Delphinium next to the scarlet Oriental Poppy; but if, on the contrary, yellow comes in between, crimson Poppies may be used. We will take blue first, for it is the colour that harmonises best with every other. Next to No. 1, the blue, we will place No. 2, scarlet; then 3, yellow; 4, purple; 5, white; 6, pink; 7, blue; 8, orange; 9, mauve; 10, white; 11, blue; 12, red, and so on.

Although blue is so harmonious that its use is most desirable in the colour scheme, blue flowers are, unfortunately, not plentiful, so we must collect all we can of every shade, arranging them so as to mix pleasingly and avoid a patchy effect, and, above all, keeping out all purple or lilac tones. This we can do by adhering to sky blue, sapphire, and indigo tones. In my present article I am not taking into consideration the background, which is bound to be different in every case. Hedge, wall, or paling may be there already, or possibly the border may be cut out of a grass terrace, and the background may have to be formed by the plants used in the bedding out. You cannot do wrong for your tallest plants to start with groups of Delphinium, choosing, as I said before, the true blue varieties; any good florist will sell you those true to colour. The hybrid Monkshood (*Aconitum Napellus*) is useful and effective, and blooms earlier than the Delphiniums; but some people are afraid of admitting so baneful a plant into their gardens, and it also has the demerit of over fertility and of being extremely unsightly in its decay. These plants I mention will all be out of flower by the end of July or earlier, but if you immediately cut down the Delphiniums they will bloom again in the autumn. Then there is one very good variety of the old-fashioned Columbine, a deep self blue, and several blue and white ones which may be admitted with *Columbina celestis* in a group and Jacob's Ladder (*Polemonium caeruleum*).

The blue annual and perennial Lupins can be placed close together for successions; the perennials will be out of flower by the end of June. There is a species of Borage Wort I found in a cottage garden which is charming, flowering continuously throughout the whole of the summer. It ought to be of great value in a border, but I do not think it is generally known; and I confess to admitting, under restrictions, its relative of the herb garden. Next plant some of the Veronicas, keeping the dwarf varieties for the front, with *Anchusa italica*, which is an early and constant bloomer. Have plenty of annual Larkspurs, Sutton's stock flowered blue, I think is the best, and will give you a wealth of bloom from May to the end of September; and I should sow Cornflowers among the other plants, for they want the support they find among the Corn, and *Nigella*, and two sorts of Forget-me-nots—the tall Perfection and quite dwarf Star of Love—and if your border is moist enough to grow *palustris* you may gather Forget-me-nots until late in the autumn. You can have fine groups of blue English Iris and the Spanish King of the Blues.

Close to the edge you must have Squills, the pretty *Chionodoxa*, Glory of the Snow, *Violas* in shades, and just behind them blue *Hyacinths*, and do try to establish the beautiful *Gentiana acaulis*, now too little grown. A hundred years

ago there never was an English flower garden without it. If you will go and see a great border of it with its thousands of green-throated sapphire bells and compact vivid green foliage flourishing in the gardens at Wisley next May, you will never rest content until you have made an effort to obtain it for your blue section. But, alas! it is like so many great beauties—very capricious. The *Campanula* tribe may be enlisted to help you in a later summer, and the blue Flax, and for the front of the border you can have a lovely Californian annual (*Phacelia campanularia*). This must be grown in boxes, and planted out when strong enough to find for itself, for the slugs devour it greedily in its infancy. The *Nemophila insignis*, too, should be sown in the previous autumn. The *Salvia patens* will come in well for the autumn, the dullest time of all, for the blue flowers seem to depart with the summer skies. These things should all be well mixed together, and planted with no niggard hand, to ensure as much as possible an effect of blue over all. You will find Ribbon Grass and variegated Maize a charming and æsthetic addition to your section, the white and green harmonising so perfectly with the soft colouring.

I am sure much more use might be made of foliage plants and grasses in this kind of gardening. Now we come to scarlet. We

must keep to the true tint, for we want the red flowers for section No. 12. What could be more effective than a fine group of *Kniphofia Matador*, if it is a real scarlet, as I believe it to be. Then we have the Oriental Poppies, which will be in full bloom in June, followed closely by *Lychnis chalcidonica*. The scarlet Martagon Lilies are due at midsummer, with *Monarda didyma*, planted reservedly, and *Delphinium nudicaule* generously. Scarlet Queen *Salvias* and *Geum coccineum plenum* will bloom from summer into autumn, and you will have plenty of *Glaucolus Brenchleyensis*, and the handsome *Physalis Franchetti* to keep them company into the late autumn. Then we have a host of smaller things, chiefly for spring blossoming. First the beautiful Turban *Ranunculus*, the most intensely scarlet of all flowers. These require care, and must never be allowed to suffer from drought; double and single *Anemones*, and the *Anemone fulgens*, which blooms very early; and *Cramoisie Tulips* and scarlet Parrots. There will be a pause, I am

afraid, after these go out of bloom before the Oriental Poppies open, but if you sow quite early a pinch of Sutton's Cardinal Poppy in patches among the other plants, thinning out severely, you will probably have these in flower first. The scarlet *Nasturtium*, a dwarf variety, is of great value, and its foliage is so pretty. Plant, too, some good clumps of Carnations; you will not beat Grenadin, though it has many rivals, for it is so hardy, and such a free flowerer. There is a really scarlet *Verbena* to be had, but I forget the name. Scarlet annuals are scarce, but if you sow the charming *Cacalia coccinea*, or Tassel flower, and if you have any spare spaces or failures you can always fill in with the time-honoured scarlet *Geranium*, though the mind of the modern florist is filled with an unreasoning prejudice against this method of plenishing.

AUGUSTA DE LACY LACY.

THE INDOOR GARDEN.

MALMAISON CARNATION CULTURE.

SHOWN in the accompanying illustration is a house of Malmaison Princess of Wales, a beautiful deep pink, probably the best in cultivation for general purposes. When I took charge of these gardens, in April, 1902, there were seven old plants of this variety, and being well acquainted with Malmaisons, I knew the value of this beautiful sort. As I had to grow them for market as well as for private use, I advised that nothing else but Princess of Wales should be grown. In August, after the flowers were cut, I disposed of all the other varieties, and kept the seven plants of Princess of Wales, which I layered on August 21 in a cool frame. They were watered and kept shaded and close for a few days. Air was then gradually admitted, and was always given night and day. They were sprayed about midday with a fine spraying Abol syringe. On September 27 I found them to be nicely rooted. I then severed them from the old plants with a sharp knife. On October 10 they were potted into 4-inch and 5-inch pots. After potting, they were placed upon coarse ashes near the glass in a cool frame, and again kept close for a few days. Air was afterwards gradually admitted, eventually leaving it on night and day. At the end of October they were removed to the Malmaison house, and placed upon the side stages covered with shell-gravel. Water was given with great care, rain water being used; air was given freely both by the top and side ventilators. The house temperature was never allowed to exceed 55° at night. However sharp the weather was, I always had a little air on the top and sides, with the heating pipes just warm so as to dispel superfluous moisture.

In February, 1903, when active growth began, they were potted into flowering pots of 6 inches or 7 inches in diameter. They were potted carefully and firmly, using three parts good fibrous loam, one part leaf-soil, wood ashes, charcoal, with plenty of sharp sea-sand, old mortar rubble, soot, and crushed bones. Some half-inch bones and a few pieces of charcoal were placed over the crocks. The plants were then neatly staked, given plenty of room, and placed on the centre stage. Water was given with care. By the middle of April they had rooted through the new soil. I then began feeding gradually with Clay's Fertilizer, giving a small teaspoonful to a 7-inch pot, and rather less to a 6-inch. This I used to apply every fortnight by sprinkling over the surface of the soil, not mixing it with the water, as most people advise, at the rate of an ounce to the gallon of water. If mixed with water and applied in this way it passes through the soil and drainage, and the roots benefit very little, especially if the plants are very dry when it is given. I used to water with weak soot-water alternately, as this helps to keep the plants in good colour.

MALMAISON CARNATION PRINCESS OF WALES IN THE GARDENS, REDLANDS, [BROADSTAIRS, KENT.

As the pots became full of roots feeding was made rather stronger, especially when they were making flowering growth in May and June. As soon as they showed colour Clay's Fertilizer was withheld, and only weak soot-water given once a week. Disbudding was well attended to, and each growth allowed to take one flower. Good long stems for cutting were thus obtained, carrying grand, well-developed blooms, the majority of them measuring 6 inches across; some measured 7 inches across. After the blooms were cut the plants were again repotted. On September 23 they were transferred from 6-inch and 7-inch pots into 8-inch and 9-inch pots, being given the same compost as before. They were then well staked out and given plenty of room, so that light and air could reach them. In February of this year they received their final potting into 10-inch and 12-inch pots. They were then given precisely the same treatment as the previous season. This year I began cutting on June 22 and finished September 2. From the house shown I cut more than 100 dozen, and the morning before the photograph was taken (July 1) I cut six dozen. I never grow plants more than two years.

GEORGE WEST.

The Gardens, Redlands, Broadstairs.

BULBS FOR THE GREENHOUSE.

(Continued from page 258.)

DAFFODILS.—These will not bear hard forcing, yet at the same time a great many of them can be brought on under glass, and in this way anticipate their usual season by some time. It is necessary to put from three to five bulbs in a pot to form an effective display. These may be treated as recommended for the Hyacinths, and when taken under glass a cold frame is at first the best place for them. While the majority lend themselves to this treatment, especial mention may be made of *Ard-Righ*, *Emperor*, *Empress*, *Countess of Annesley*, *obvalaris*, *Telamonius*, *Telamonius flore-plena*, *princeps*, *pallidus præcox*, *Golden Spur*, and *Horsfieldi*, while the large flowers of the double forms of incomparables are very showy when at their best.

CROCUS, **CHIONODOXAS**, **MUSCARI**, and **SNOWDROPS** are all available for growing under glass, and afford a pleasing variety. They, as well as the different *Narcissi*, need rather more loam in the soil than *Hyacinths*, otherwise their treatment is much the same. Pots 5 inches in diameter are very useful, and the number of bulbs in each will depend upon their size, for in the case of such small ones as the *Chionodoxas* a dozen is not too many. All these should be potted before the end of October, and after making roots out of doors should be taken under glass. The *Snowdrops* is, as might be supposed, the most impatient of fire-heat, but with care this will flower well in pots, and that, too, before those out of doors.

LILIUMS.—The various *Liliums* differ from any of the plants mentioned, in the bulb being composed of scales more or less loosely arranged, hence they suffer from exposure much more quickly than the firm bulbs of *Hyacinths*, *Tulips*, *Narcissi*, and such things. This being the case, it follows that they should be potted as soon as possible after receipt. Of the different *Lilies* usually grown in pots for greenhouse decoration we get *L. longiflorum Harrisii* from Bermuda about the middle of August, *L. longiflorum* and varieties from Japan in October and November, and *L. auratum* and *L. speciosum* both represented by several varieties in December and January. They should be potted on receipt and placed in a cool structure, just giving enough water to keep the soil slightly moist till growth recommences, when an increased supply is necessary. Of the others previously mentioned *L. Harrisii* may be treated in the same way, while the Japanese *L. longiflorum*, *L. auratum*, and *L. speciosum*, after potting, should be placed in a cold frame till it is necessary to take them into the greenhouse. In all stages of growth *L. longiflorum* is particularly liable to be attacked by

aphides or green fly, which may be readily kept in check by vaporising.

THE TUBEROSE (*Polianthes tuberosa*) is another bulb of which we receive our supplies entirely from abroad, chiefly from America and South Africa. From the last-named district the bulbs usually reach here in October, while the American ones do not come till December. These do best if potted firmly in good loamy soil and grown in a fairly humid atmosphere. They may be kept out of the ground for a couple of months without injury, and if potted in batches at intervals of two or three weeks a succession may be kept up for some time.

FREESIAS.—Despite the fact that *Freesia* bulbs will, with reasonable attention, perfect their growth and flower well year after year in this country, immense numbers are imported every season, principally from the Channel Islands and the south of France. The major portion consists of the white-flowered form known generally as *F. refracta alba*, but which, as pointed out by Mr. Gumbleton some time since in THE GARDEN, has no connexion whatever with *F. refracta*, which is a poor garden plant and quite scentless. The true name of the popular kind is *Freesia alba*. The bulbs of this reach here about the end of July, and should be potted before the end of August. A very convenient way of growing *Freessias* is to put about eight bulbs in a pot 5 inches in diameter in a compost made up of good yellow loam, dried cow manure, and silver sand. During the growing period the plants should be in a light position in the greenhouse, while a free circulation of air is very necessary. Besides the above there are numerous other bulbous plants grown to a greater or lesser extent for the embellishment of the greenhouse, and of them the *Babianas*, *Ixias*, and *Sparaxis* may be treated in much the same way as the *Freessias*. Beside these there are what may be regarded as permanent greenhouse plants, that is to say they may be grown and flowered year after year without difficulty. This class includes the following: *Crinum*, *Cyrtanthus*, *Hæmanthus*, *Hippeastrum*, *Lachenalia*, *Nerine*, *Urceolina aurea*, *Vallota purpurea*, and some of the *Watsonias*.

H. P.

THE FLOWER GARDEN.

WILD GARDENING IN SPRING.

AS this is the first paper of this description I have ever written or read, I must ask for your kind indulgence this evening. I have tried my best to make it both practical and interesting, and am hopeful it may prove, to some at least, a little instructive as well. I have thought it better to confine myself almost entirely to the naturalisation of spring flowers in grass, and to give my personal experience in a small way, extending over a period of some ten or twelve years.

I believe no other class of gardening offers so many varying opportunities to obtain results so fascinating and calculated to give lasting pleasure. It seems to me to give a maximum of satisfaction for a minimum of trouble and expense. With a little forethought and a judicious selection of bulbs, one may, by the expenditure of a few pounds, have an extensive and charming show from early in February to the approach of June. I know of no more agreeable occupation in the garden, at any season of the year, than that of arranging and planting bulbs on a fine day in autumn.

Another great advantage of flowers grown in this way is that they have a special charm of their own. My experience is that no matter how beautiful the later blooms of summer and autumn may be, they do not seem to be so keenly appreciated as are the early flowers of spring, when grown in the grass.

As regards the finding of suitable places and positions, it has often struck me that it would well repay many otherwise keen gardeners to thin out some of their more ugly shrubberies, and

instead of keeping up acres of troublesome and expensive lawns to give up a good portion of the available ground to this class of gardening. If they once did so they would never regret the change I feel confident, and it would prove to be an ever-increasing source of pleasure. The work of planting, too, comes at a time of year when the other work of the garden is not so urgent, and when once finished you may confidently look forward to a good show in the spring. This more especially refers to

THE DAFFODIL

(after all the most graceful of spring flowers). I know of no other flower that is so happy, so hardy, and such a consistent bloomer. No matter what the season may be, up it comes in the grass in due course as fresh as ever, and it has another good recommendation—none of the vermin tribe will interfere with it. Even our old and familiar friends the birds, rabbits, mice, slugs, &c., although they will sample most things pretty freely, when they come to the *Daffodil* they, as it were, give it a wide berth and pass by on the other side.

In giving advice about planting it is hardly necessary for me to warn intending planters to avoid the slightest suspicion of a straight line or formality of any sort or description. When planting a fresh spot my own plan is to make 100 or 200 holes and mix early and late *Daffodils*, *Tulips*, and *Hyacinths* in an open basket, and plant them in a haphazard sort of way. This I know is not considered to be the orthodox plan, or the system advised by experts to be adopted. We are, I think, advised to plant the different varieties in separate groups by themselves, and possibly, where you have many acres of grass, this plan answers fairly well. But where space and funds are limited, as they mostly are, the object we should aim at, I take it, is to get as continuous and as pretty a show for as long a period as possible on the same plot of ground, and by my system I think I may claim to have moderately well attained this. If you plant in small groups, say early and late *Daffodils* side by side, as soon as the early ones are over the whole effect is marred by masses of faded flowers near those in bloom, whereas with only a few faded ones here and there they are scarcely noticed.—Paper read by Mr. A. TROWER at a meeting of the Redhill, Reigate, and District Gardeners' Association, September 27.

(To be continued.)

HARDY FLOWERS FOR CUTTING.

(Continued from page 260.)

SOME of the *Campanulas* must not be omitted, especially some of the varieties of *C. persicifolia*, though they are of very short duration in hot weather. The best are *C. p. grandiflora*, single, with blue flowers 2 inches across, and *C. p. grandiflora alba*, with large single white flowers. Both grow about 2 feet in height and flower in early July. The double and semi-double varieties are not so good. *Scabiosa caucasica* is a most valuable perennial where it succeeds, but it is often a failure on cold wet soils, as also where slugs are busy, as it is one of their favourite delicacies when it is trying to shoot up in the spring. There are several good varieties, the best being *S. caucasica magnifica*, which has flowers 2 inches to 3 inches in diameter, almost pale sky blue, inclining to lilac. The rarity of flowers of this colour makes it specially worth trying to grow.

A most useful white flower for cutting, principally in July, though it is of no great beauty in itself, is *Achillea Ptarmica flore-pleno*. It is known as *The Pearl*, and the original type of the plant is the British *Sneeze-wort* (*Ptarmica vulgaris*). If the blossoms are all cut off after the first crop is over it will usually produce a second crop. It grows about 3 feet in height, and sends up shoots so thickly that it is necessary to thin them out, as they are naturally very slender and need some support, and this weakness is accentuated if the stems are too close together.

Of the *Globe Thistle* the best is *Echinops Ritro*, a large, strong-growing plant 3 feet to 4 feet high, bearing globular heads of blue flowers. Some prefer

ruthenicus, which has a smaller habit of growth, and has blue ball-shaped heads of blossom 2 inches in diameter. Both will grow in any ordinary garden soil, but they are not adapted for small gardens as they need a deal of space. They are effective for indoor decoration in large vases, and as they have handsome leaves covered with silvery down they look very well if arranged by themselves.

A different kind of Thistle-like flower is the Sea Holly, which, though no one would think it upon first acquaintance, belongs to the order of the Umbelliferae—the Hemlock family. There are several species which are grown in gardens, the best being *Eryngium olivierianum*, 3 feet high, of easy cultivation; *E. amethystinum*, 2½ feet high, the spiny involucre of which is of a fine amethyst blue; and *E. alpinum*, 2 feet high, with soft bracts, which, as well as the stems, are of a beautiful blue. These three will grow in almost any soil provided it is well drained, but otherwise they are liable to damping off in the winter. They are easy to raise from seed, and it is well not to attempt to increase them by division, as they take a long time to recover from the operation. They are said to come a brighter colour in a light sandy or chalky soil.

The *Marguerites* must not be forgotten, and the best for cutting is undoubtedly *Chrysanthemum maximum*, or one of its hybrids, *C. m. grandiflorum*. This last has large flowers 4 inches in diameter, which last a long time in water, and are very effective. If picked soon after the flowers expand, or before the disc florets begin to develop, they will last for nearly a fortnight in water. It grows about 3 feet in height. The remark about the development of the disc florets applies to all Daisy-like flowers. Coming to the

SEPTEMBER AND OCTOBER

flowering plants there are three indispensable classes which should be in every garden. One is the Japanese *Anemone*, or *Anemone japonica*. Many new forms in various shades of pink have been introduced in recent years, but there is none to beat, or even equal, the *Anemone japonica alba* Honorine Joubert, with large white flowers and greenish yellow centres. It does best in a slightly shady position, and should be left undisturbed for years.

The second class, which is indispensable, is an infinitely larger one, and that is the perennial *Aster*, or *Michaelmas Daisy*. They will grow anywhere, and some are so rampant in their growth that they will crowd out other things. Such varieties should be in the margin of the shrubbery or wild garden. There are two main classes from the decorative point of view—those which are grown for the beauty of their individual flowers, these being from half an inch to 2 inches in diameter, and those which produce long sprays of minute flowers which are so charming when mixed with other things, and almost take the place in autumn which the *Gypsophila* occupies in the summer. There are many *Michaelmas Daisies* which do not come within either of these classes, and such should not be chosen if indoor decoration is one of the objects in view, as they are not effective. Of the purely decorative class one of the best is *Aster cordifolius* elegans, producing long graceful sprays of soft lilac flowers in great profusion, and growing 5 feet high. But the varieties in both classes are so numerous, and the colours, habits of growth, and size of flowers so various that no selection could be made in an article of this character.

The third indispensable class is the early-flowering section of the *Chrysanthemum*. This is another very extensive class, and is becoming more so every year. Some will bloom in August and even in July, while others continue into November in a favourable season. They should be pinched back to keep them bushy, and by this means those inclined to bloom in August, when they are not wanted, can be made to bloom at *Michaelmas*. Three of the best varieties, all flowering in September and October, and growing from 2 feet to 3 feet in height, are *Mme. C. Desgrange* (white), *Orange Child* (deep yellow), and *Harvest Home* (bronzey red).

NOVEMBER AND DECEMBER

are necessarily almost barren of flowers, though foliage, seed-pods and berries are often beautiful. The Christmas Rose should have the protection of a hand-light to keep the flowers clean. The Winter Heliotrope (*Petasites fragrans*) is very acceptable in a mild season and very sweet scented, but severe frost kills the blossoms. These are the only two plants outdoors that are of much use for cutting at this season in most parts of the country. Favoured places in the south and south-west are, of course, much better off in this respect. But if a shrub may be included among hardy perennials, there is the Winter Jasmine (*Jasminum nudiflorum*), which will flower the whole winter in any aspect in a mild season, and opens well in water in a warm room, also the Winter Sweet (*Chimonanthus fragrans*).

The above list of plants is not, of course, exhaustive. The flowers named are the best for cutting at the different seasons of the year, all being free blooming, easy of cultivation in ordinary soil, and most of them lasting a good time in water. Some of those with tough stems, like some of the Sunflowers, are apt to flag sometimes very soon, and vary in this respect in a most unaccountable manner. This tendency may often be lessened by splitting the stems 1 inch or 2 inches up, or by cutting fresh pieces off the ends just before they are placed in water.

ALGER PETTS.

A GENERAL CALENDAR.

THINNING OUT CLIMBING AND POLE ROSES.

NOW is the best time for this necessary operation. If the plants are relieved in autumn of all the very old wood the remaining growths stand a better chance of ripening, and will consequently be the better fitted to pass through a severe winter without injury. The eggs of troublesome insect pests are usually deposited upon the old wood, and to destroy them means less trouble in spring. It is surprising how vigorous-growing Roses are helped by cutting away the worn-out wood. If this is allowed to remain the best eyes at the base are prevented from breaking, and the plants in a few years become unsightly and worthless. There is also a great difference in the trusses of blossom produced from wood not more than two years old, while those emanating from poor, twiggy shoots are always unsatisfactory. When Roses upon walls and trellises have been neglected, the present is just the time to clear away a lot of this superfluous growth. It may not be convenient to thin out such plants as one could wish, but a start should be made. Then, if they are annually treated as advised, a change for the better will be the result.

Fuchsias.—Good cuttings are difficult to get at the end of the summer, but by looking over the plants which have been bedded out young growths free from flower-buds can be obtained, the recent rains having induced growth at the expense of flowers. These should be inserted in small pots and placed in a propagating pit. Here they will soon root. Give pot room as required, keep them growing in a temperature from 55° to 60° through the winter months, pinch the lateral growths, and allow the centre growth, secured to stout stakes, to run up at will. Good plants may thus be obtained by bedding out time from 4 feet to 5 feet in height. Varieties suitable for this purpose are *Mrs. Marshall*, *Rose of Castile Improved*, and *Ballet Girl* (a good double).

Gathering fruit.—By this time most fruits will have been gathered, though there may still be some of the latest Pears hanging. Medlars and Quinces are still on the trees in some places. The first dry day should be chosen to finish up all the work of gathering, for the fruits will not improve by being left on any longer. Medlars should never be placed in the same store as other fruits, for the moisture arising from the latter will be sure to spoil them. The only place in which they will ripen properly is a dry one, where they can be kept cool as well.

Walnuts which have been gathered and placed in heaps should now have the pulpy outside casing removed from the shells, the latter should be rubbed dry and the Nuts stored in Rhubarb or Seakale pots placed upon a stone floor. Here both Walnuts and Filberts will be found to keep well. It will be necessary to overhaul the fruit proper frequently, removing all that show the slightest signs of decay. It is during the first few weeks after storing that such fruits are sure to be found, for, in spite of every care, some blemished ones are sure to find their way to the shelves.

Currants on north walls.—The usefulness of these cannot be over-estimated; they are both useful and ornamental. I prefer cordons, double or single, as grown thus the trees may be kept closely spurred in and the space more quickly filled. There is no difficulty in protecting trees grown in this way, and the fruit will keep sound for weeks after the crop on the bushes is over. Such kinds as *Reine Victoria*, *Raby Castle*, *La Versailles*, and the *White Dutch* lend themselves readily to this mode of culture.

Strawberry St. Joseph.—This variety is proving most useful this autumn; the colour and flavour are all that can be desired. The fruits are not large, but they are produced freely, so that what is lost in size is made up in quantity. Plants potted up early in small pots should now be placed on shelves near the glass, and, if needed for any special purpose, it is surprising what quantities of fruit small plants will furnish.

Green Mint.—In winter dried Mint is very useful for soups, &c., but fresh green Mint is decidedly better, and there need be no difficulty in securing a regular supply throughout the whole of the winter and early spring; in fact, until the outdoor plants begin to grow again naturally. But, in order to accomplish this, two things are indispensable, the first being a healthy, vigorous bed of well-established plants in the open air, and the second a well-heated greenhouse or pit. A fortnight or so before the first cutting of young Mint is wanted, take up one or more good masses of these roots, according to the quantity required, the best way being to cut them out with a sharp shade, getting well down below the "mat," and lifting each piece with plenty of soil on the roots. Lay them out on a bed of good light and rich soil in the greenhouse or pit, or in boxes will do, covering them with 1 inch or 2 inches of the same material, and give the whole a good watering in a genial temperature of 50° to 60°. The roots will soon begin to grow, and when 3 inches or 4 inches high the young shoots may be cut or the lower leaves simply picked off. Fresh shoots will keep on pushing up for some time, but after a while the roots become exhausted, and must then be turned out and a fresh batch introduced.

T. B. FIELD.

THE ROSE GARDEN.

ROSE LONGWORTH RAMBLER.

LAST year Rose Longworth Rambler was very disappointing; it appeared to dislike the dull weather and the almost continuous rainfall of the summer and autumn. It made one appraise this Rose at a much lower valuation than usual. This year, however, it has been much better, and has flowered continuously from early summer until now. It is still in bloom, pleasing every one with its light and informal-looking crimson flowers. As a pillar Rose it is most valuable, but its behaviour last year points to the necessity of giving it a warm and dry position as compared with many others Roses.

S. ARNOTT.

ROSE WHITE PET.

WHAT a splendid bedding variety this is, flowering continuously all the summer and far into the autumn. It is vigorous, yet never seems to make much growth actually, but continues to throw up sucker-like shoots, each terminating in a huge cluster of pure white flowers, yet with perhaps the faintest

dash of pink at the back of the petals. For covering a bank this is a glorious Rose, and should not be planted too thickly, as in that way it loses its individuality somewhat. E. M.

ROUND ABOUT A GARDEN.

AUTUMN VISITORS.

AUTUMN in the country is the season of strange visitors in the garden—visitors who are often extremely unwelcome from the gardener's point of view, but whom you have hardly the heart to expel at sight. A healthy covey of artridges, enjoying a dust bath in the surface of a sunny flower-bed, make almost as much disorder as a scratching hen; but even from the door you can hear the distant popping of guns in the fields beyond the paddock, and you feel half inclined to go out quietly by the other gate and leave the partridges to enjoy a morning of peace in life even during the shooting season. But they usually settle the question for you, and whirr away over the shrubbery as you emerge from the porch; and if they choose to circle round and come in again presently by the kitchen garden, that is the gardener's concern.

A WILY OLD TRESPASSER.

The solitary cock pheasant presents a different problem. When he catches sight of you, he merely bolts, tail in air, for the nearest shrubbery, through which by devious ways he hurries to the furthest cover that the garden contains. He is an old campaigner, and has no intention of returning to the fields just yet. There are too many men with guns and dogs about for his liking, and he seems to know, either from experience—the experience of deceased friends—or by happy intuition, that men do not shoot pheasants among Chrysanthemums and Cabbages. Yet a pheasant among the flower-beds is almost worse than a hen—which one naturally takes as the lowest type of feathered hooligan in a garden—and you know that this wily old cock, who always saves his skin by running like a greyhound in the shooting season and bullies all the younger cocks in the breeding season, ought to be shot for the good of the estate. But, like the partridges, he settles the question for you, only in an opposite matter; for how can you drive a bird off the premises when he has disappeared into a damp shrubbery and you do not know where he went after that? Besides, a cock pheasant, parading about the lawn early tomorrow morning, will certainly be a fine feature of the garden from your bedroom window, and "Live and let live" is not a bad motto anyway.

THE INFLUX OF WILD BIRDS.

In a game-preserving district, however, it is better in the long run to fence the garden with wire netting which will keep out the hares,

and most of the pheasants and partridges without preventing the influx of the wild birds whose presence one values the more in proportion as the flowers become fewer and the trees grow bare. And there is no doubt that shooting in surrounding fields is a great aid to stocking a garden with bird-life. All the fugitives do not come to stay, for the resident birds of the garden have their own ideas about trespassers, and there are often lively times while your own robins, thrushes, and blackbirds are explaining to the intruders that their company is not desired. But there always remains a residue which successfully resists expulsion, or has been lucky enough to find corners where no resident birds seem to claim vested rights. Thus the garden becomes full of feathered life,

THE NEW CAMPANULA HYBRIDA FERGUSONII.

(Given an award of merit at the Royal Horticultural Society on September 6, 1904.)

and often your lawns and shrubberies will be visited for a day or two by rare and shy strangers not usually seen so near human dwellings. For the sportsman's judicious plan of campaign, whereby the game is gradually driven towards the central fields where the great "shoot" of the season will take place, has a similar effect upon bird-life in general, with the exception that this is allowed to break away unmolested, and to find asylum from the din of firearms in any quiet coppice or garden.

DISTINGUISHED STRANGERS.

After one or two experiences, the small birds are remarkably quick to discover such safety

spots, and as the shooting draws near you can see them hurrying thither from all sides. So, too, when the shooters have once or twice flushed a short-eared owl among the turnips, it may be your turn next to discover him, by the noise that the sparrows are making, lurking among your cabbages; and a moorhen stalking on long angular legs about the margin of the lawn seems a nobler fowl than when, with its legs dangling behind, it hurried in low flight from field to field before the line of dogs and guns. It is, no doubt, the narrow landscape of a garden which seems to dignify each unusual bird which visits it in autumn. The green woodpecker, which flits across the park in looping flight from tree to tree, seems an ordinary bird enough; but in your garden, where you can watch him at close quarters, with his erected crest and upright carriage on the lawn, with his quaint, hammer-headed outlines, and his contrasting hues of crimson, green, and a flash of vivid yellow as he flies, he looks like some rare curiosity of the tropics.

E. K. R.

IN A SURREY GARDEN.

IN the garden at The Hollies, Weybridge (the residence of Mr. G. Ferguson), woodland and water, flowers and foliage are delightfully commingled. As may be seen from the accompanying illustration, Nymphaeas stud the surface of the lake, the giant-leaved Gunnera and graceful plumed Cynerium strike a note of dignity by the margin, beds bright with flowers surround the house, which itself is creeper-covered, while on the other side of the lake the cultivated garden passes gradually into the wild garden, and this, again, to woodland. Thousands of bulbs are asleep in the grassy mounds and banks beneath the forest trees, and at the magic touch of spring will cover them with masses and drifts of yellow and green, in shades such as only the flowers and foliage of Daffodils can show, while even before them Scillas blue and Snowdrops white will herald the beginning of a new year. The alpine garden contains many gems among miniature plants, which cover rocks and stones and soil with lovely bits of colour in their season, when the wilder garden

loses its spring beauty in the sleep of summer. Thus, as flower gives place to leaf in one place, leaf is smothered with flower in another, and the garden retains an interest, and a beauty too, almost from New Year's Day to Christmas.

When recently we visited the gardens the Delphiniums, of which there is a splendid collection here, most of them hybrid forms raised by Mr. F. W. Smith, the head gardener, were still bright, the pure shades of blue represented being most attractive. Mr. Smith has done a good deal of successful hybridising among garden plants. The Campanulas are the last he has turned attention to, and only a few

weeks ago the floral committee of the Royal Horticultural Society gave an award of merit to Mr. Smith's hybrid *Campanula Fergusoni*, the result of a cross between *C. pyramidalis alba* and *C. carpatica*. The illustration we are able to give of this shows its habit and the form of the pale blue flowers, as well as its floriferousness. There was some doubt as to whether it would prove to be perennial or biennial, but Mr. Smith writes that "the plants are throwing up numerous growths from the base, thus proving them to be perennial. I have reason to believe that it can be had in flower the greater part of the year." For conservatory decoration, and also probably for culture out of doors, this new *Campanula* promises to be of much value. Many other plants are well grown at The Hollies, and this is undoubtedly due to the fact that Mr. Ferguson takes such a keen interest in his garden, which, as may be seen at a glance, is full of possibilities. An inspection shows that they have been taken full advantage of.

RIVIERA GARDENS.

THE nature of the soil of the Riviera is exceedingly varied. At Cannes, in the west, the ground more especially back toward the hills, consists almost entirely of rock. To bring this into a fit state for the cultivation of plants it has first to be broken up with a pick; afterwards the action of the atmosphere and rain, together with artificial watering, crumbles it in a very short time. After two or three years continued manuring it becomes most fertile. All the choicest Palms thrive in this soil without the addition of peat or other materials. This is also the best compost for the Acacias, which cannot be grown in soil containing chalk, however rich and well cultivated it may be. It is for this reason that the Acacia will not thrive at Nice, Beaulieu, Mentone, or, in fact, anywhere to the east of Cannes. Beyond Cannes, in the direction of Nice, where the mountains are a greater distance from the sea, the soil changes completely, becoming alternately a sandy loam or a dark brown loamy soil containing much chalk. It is, generally speaking, very poor, the cultivation of the Olive for the last few centuries having greatly exhausted it. Just before reaching Nice, on the borders of the River Var, there is a large plain, several square miles in area, the soil of which is of a rich sandy nature to the depth of 3 feet or 4 feet. This plain is really the vegetable garden and orchard of the Riviera, where Asparagus, Peaches, and Strawberries are grown in considerable quantities. A few portions, each comprising more than ten acres of ground, are devoted entirely to Peach culture. The Asparagus grown in this district rivals in excellence the world-famed product of Argenteuil. Immense quantities of Strawberries are also cultivated. It is too much exposed here for the cultivation of flowers out of doors in winter, with the exception, however, of Princess of Wales and Parma Violets. On the western side of the Riviera by far the commonest tree is the Aleppo Pine (*Pinus halepensis*), which covers many miles of mountain slopes and hillsides. The cones of this Pine are here largely used as firewood.

Notwithstanding their comparatively recent formation, Riviera gardens now have a most varied and luxuriant vegetation, almost tropical in character. Palms form the principal feature. *Phoenix canariensis* is one of the most commonly planted, and succeeds well. This and *Washingtonia*

filifera are frequently planted in avenues, and then have a fine bold appearance. *Phoenix dactylifera* (the Date Palm) is also abundant. In some gardens it produces and ripens its fruit. This species is largely planted along the seashore at Cannes, Nice, and other towns. *Cocos plumosa* develops into a large tree. It is not uncommon to meet with it 50 feet high. Some of the older specimens flower and fruit annually. The magnificent clumps of Bamboos are a feature of Riviera gardens.

The flower-beds of these gardens present a great variety of form and colour. Such gorgeous displays as we see there during winter always impress the visitor to these Mediterranean shores. To keep these beds bright from November to April two almost distinct plantings are necessary. The plants put out in November furnish the first display, and are supplanted about February by others. As the season is so short the majority of plants are necessarily near the flowering stage when transferred to the beds. The primary

are often damaged and sometimes partly washed away by the heavy autumn rains. Every garden is provided with stone gutters by the side of the walks, but even these are sometimes insufficient to carry off the water quickly enough.

The area devoted to flower farms, where whole fields are cropped with beautiful and odoriferous flowers, is a very considerable one, and comprises the towns of Nice, Cannes, and Grasse. Certain localities in this area have their own peculiar floral output. For instance, Cannes, Nice, and Antibes are famous for Roses; Grasse for its Jonquils, Violets, Tuberoses, Jasmine, and Mignonette; Hyères for Violets; and the suburbs of Cannes for Pinks. In the matter of profit, the districts of Cannes and Antibes rank first; excellent returns are also secured around Golfe Juan and Beaulieu. The total area actually cropped with flowers is nearly 1,800 acres. In packing flowers for transport great care is taken to have them dry. The more delicate ones, before being sent away, are hung up by the stalks in a room, so that all

VIEW IN THE GARDENS AT THE HOLLIES, WEYBRIDGE, THE RESIDENCE OF MR. G. FERGUSON.

occupants of these are *Salvias*, *Daisies*, *Primulas*, *Pansies*, *Solanums*, *Carnations*, &c. These are followed by *Cinerarias*, *Freerias*, *Ranunculuses*, *Hyacinths*, *Tulips*, &c. *Anemones* do very well on the Riviera. Mixed beds of them are often seen. *A. fulgens* is usually planted in beds by itself, and the multitude of bright red star-like flowers the plants produce fully justify this indulgence. Occasionally one meets with beds filled with forced Roses of such varieties as *Baroness Rothschild*, *La France*, *Ulrich Brunner*, &c. *Pteris tremula* and some of the hardy *Adiantums* are planted in beds with various other plants.

The routine work of these gardens is very different from that of our English ones. In April, when all the visitors have returned northwards, the lawns are roughly dug over. They remain in this state throughout the summer, and during that time bear a great resemblance to ploughed fields. It is, however, quite necessary to treat them in this way, otherwise the grass would be completely burned up by the hot sun. In October the lawns are again dug over, levelled, raked, and resown. The newly-sown lawns, especially those on a slope,

moisture may be dispelled from them. In packing the baskets flowering shoots of *Acacia* form the first layer, the centre being filled with choicer blooms wrapped in tissue paper. France alone consumes half of the Riviera output; Paris, with its numerous flower shops, fêtes, and other festivities is, of course, the principal market. Z.

TREES AND SHRUBS.

THE CRATÆGUS AT KEW.

WELL worth a visit from those who are interested in ornamental fruiting trees is the collection of *Cratægus* between the Temperate house and the Pagoda at Kew, for the majority of the specimens are carrying large crops of fruit. For planting in shrubberies, on lawns, or for grouping in large masses in parks and plantations, many of these Thorns are well suited. They can be relied upon to flower well annually, while the majority fruit

freely each year as well. The leaves of some species colour brilliantly also. The following are some of the best:

C. monogyna, one of our common British Thorns, is smothered with small, deep red fruits, but in bounty it is surpassed by several of its varieties, such as *pionatiliba*, *eriocarpa*, *fuscata*, and *granatensis*, all of which produce larger and more showy fruits than the type. Another variety of *C. monogyna* that is very showy is *C. m. var. ramulis aureis*; on this the fruits are very bright red, while the leaves have taken on a very pretty yellow tinge.

C. orientalis is a distinct species from the Orient, with very hairy leaves, young wood, and fruit. The colour of the fruit is orange-scarlet, and it is about the size of a small Cherry. There is a variety called *sanguinea*, with deep red fruits, and a form of the type with red and yellow mottled fruit. A species somewhat like the last-named in leaf, and coming from the same country, is *C. tanacetifolia*; the fruit is, however, yellow, with a slight red flush on the sunny side, as large as a Siberian Crab, while the calyx lobes are erect. *C. pinnatifida* is a Chinese plant easily recognised by its large leaves and distinct red fruits. The variety *major* is, however, much finer, the fruits being as large as good-sized Cherries.

C. Crus-galli (the Cock's-spur Thorn), from North America, is particularly showy, and a certain fruiter; the fruits are large and bright red. There are numerous varieties, of which good ones are *arbutifolia*, *fontanesiana*, *ovalifolia*, *prunifolia*, and *splendens*. The leaves of these colour brilliantly in autumn. *C. coccinea* is a native of the Eastern United States, and, like the foregoing, is very striking, the fruits being in large heads, red, and showy. *C. Azarolus var. Francois Rigaud* is conspicuous by reason of its immense crop, while *C. macrantha* is very distinct on account of its smooth, round, coral-like fruits.

C. punctata is represented by several large trees in as many varieties. *C. p. var. brevispina* has deep red, *C. p. var. xanthocarpa* yellow, and *C. p. var. striata* red, green, speckled, and striped fruit, while that of the type is red and green. Among the others *C. nigra* is very conspicuous by reason of its black fruits, while some bushes of *C. Pyracantha* are smothered with orange-scarlet berries.

Possibly *C. mollis* is the most conspicuous, every branch being loaded with fruits of the most showy character. The individual fruits are large and bright red, while they are borne in good-sized clusters, added to this the leaves are turning to a pretty shade of yellow. *C. Carrieri* and *C. Douglasii* have not yet coloured well; when ripe the fruit is orange. *C. cordata* likewise is not at its best yet. In addition to those already mentioned, *C. succulenta*, *C. flava*, *C. mollis var. tillæfolia*, *C. dippeliana*, and others are all good.

W. DALLMORE.

THE FRUIT GARDEN.

SOME NEW LATE PEACHES.

AT this season the Peach claims considerable attention from growers who wish to maintain a good supply of dessert fruit. The past season has not been unfavourable for testing the merits of the newer sorts that fruited during September.

In writing on the merits of either Peaches or Nectarines the soil and situation must be considered. On heavy clay soils or land needing drainage the same results are not secured; in places near the coast the fruits may ripen earlier; while in the midlands or the northern parts of the country they would be later. In some places it would be unwise to plant the latest fruits, as they would fail to mature.

There is no lack of midseason varieties; for instance, *Bellegarde*, *Dymond*, *Stirling Castle*, *Royal George*, and *Crimson Galande*. Some of these are not always reliable; for instance, even under the best culture *Royal George* in a wet

season gets mildew badly. So far I have not found this defect in the new kinds: they are excellent growers, and crop grandly. Thomas Rivers comes first among the new late Peaches. This season has proved it to be a splendid acquisition. As regards flavour it compares most favourably with the older kinds noted above, and, though in this part of the country the nights lately have been cold and we have had several rainy days, which are not favourable to ripening Peaches, the new Thomas Rivers is very good. It grows freely, sets well, and should make a splendid cool house variety for use early in September. It was raised by Messrs. Rivers and Son, Sawbridgeworth. This new Peach was given a first-class certificate by the fruit committee of the Royal Horticultural Society in 1898, and was at the time considered to be a splendid addition to the late kinds, and certainly it deserved the award. It crops grandly, and should find a home in all gardens. The raisers recommend it as a good forcing variety. To show its good forcing properties, I may add that Messrs. Rivers staged this Peach on June 28, 1898, and I saw some splendid pot trees a little later this season. The fruits grown thus were very large and of deep colouring.

The next new variety that I find equal in every respect to the best of the older fruits is the Late Devonian, which was certificated a few years ago. This new fruit, as its name implies, is from Devon, and was raised by Messrs. R. Veitch, Exeter. We find it one of our best open wall fruits for use late in September. We planted it on two different sites, viz., facing west and south-west, and on the latter it is a grand fruit, large, and beautifully coloured. It was raised from a cross between Early Belle de Vitry and the better known Late Admirable. I consider it superior to the last-named in flavour. The fruits are large, handsome, and highly coloured; the skin is greenish yellow on the shaded side, and a rich dark crimson on the reverse; the flesh is pale yellow, tinged with red. The fruit is in season in late September.

Another new late Peach that will, I think, make a name for itself is Duchess of York. This I have not yet been able to give a trial, but hope to do so. It is of splendid flavour. It was sent out this season by Messrs. Bunyard. Last year a new late Peach called *Libra*, a large fruit of high quality, a seedling that the late Mr. Blackmore raised, was sent out by Mr. Tayler of Hampton; it should prove interesting to fruit growers, and valuable also if it crops well. The quality and size are excellent, and the fruits are handsome. Mr. Tayler thinks highly of it for wall culture.

G. WYTHES.

RASPBERRIES AND STRAWBERRIES IN AUTUMN.

(Continued from page 262.)

PERPETUAL-FRUITING STRAWBERRIES.—These are the result of crossing the Alpine with the summer-fruited varieties. They are very useful indeed for autumn cropping, being reliable even under such seasons as the present, but are a degree later in arriving at maturity. The best position for them is a warm border where all the sunshine during the autumn can benefit them. Our plan is to pick off all the early or first crop of flower-trusses, in order to concentrate the vigour of the plant upon the secondary growth and the spikes that succeed the same. In this way I find that we gain something in point of time and likewise in the crop. This season, for instance, the first fruits of *St. Joseph* were ripening the third week in August—these came in extremely useful for kitchen use. Part of the stock of these Strawberries is grown in pots in order to extend the season until the end of October and sometimes into November. The runners to provide this crop are layered right away into 4½-inch pots as soon as we can secure them. I like to see them all layered by the middle of July, and well rooted by the end of the month. By the middle of August or thereabouts they will be fit to take off, and by the end of the month the first flower-trusses will be showing, so precocious are these young plants.

A light, sunny position should be given this stock whilst still out of doors. The earliest will be fit to house by the middle of September. In doing this the better plan is to make a selection of the forwardest plants. Give them at once positions near the glass, on shelves if possible, as with the spring-fruited stock. Later batches can be brought in as may be desirable, but it will be found the better plan to house all that are showing flower by the first week in October. A freely ventilated house is the best place for them, no artificial warmth being needed until October is well advanced. By using the syringe freely there should not be any fear of the red spider. As these plants go out of bearing, they are set aside for the next season's crop in the open border, being planted out as soon as convenient. It is not expedient on the whole to save the old stools over for the second season's crop in the open. It may be done—in fact we have them still at Gunnersbury in good bearing, October 13. These plants are put out at about 2 feet each way. In wet seasons like the present we find a great benefit by using bell-glasses to cover the plants. (The *cloches* of the French growers are what we use; these in the spring cover the earlier crops of Lettuce, and in two seasons will well repay their initial cost.) These should be put over the plants by the middle of September. Before doing it, however, it is a good plan to go over the plants and take off any superfluous foliage, afterwards propping up the fruits upon sprays made of old Birch brooms, or by means of wire supports, so as to keep them quite clear of the ground. Of these Strawberries we grow about 1,000 yearly in pots, planting out only the best afterwards. *Varieties*.—The pioneer of this section was probably Louis Gauthier. We do not grow this now, as it fruits in autumn only upon the runners, whereas all the following fruit upon the old stools in addition: *St. Joseph*, recommended for its cropping qualities more than for its flavour; *Jeanne d'Arc*, similar to, but on the whole better than, the preceding; *Oregon* and *St. Antoine de Padoue*—these I have bracketed, for they are very similar; they are the two best autumn-fruited varieties for dessert, cropping well, and of good flavour; both are similar to *Royal Sovereign*.

By means of plants that have been forced the previous spring.—For several seasons in succession we have derived part of our crop by this method. Some of these fruits, picked in the open, were shown before the fruit committee at the first August meeting of this season. These came into bearing soon after the last of Latest of All were gathered. We select for this purpose the earlier forced plants—those that ripened their first crop about the middle of April. I prefer these to the later stock, which is not always so reliable for second fruiting, but tends rather to make a luxurious growth. This year we planted out those chiefly that were forced in 4½-inch pots, and, with the favourable time for establishing them in May, we found them to succeed very well indeed. We do not plant out all from one stage of forced plants for the obvious reason of securing a succession. (It is well known that these plants, even if they miss fruiting in the autumn, will yield a heavy crop under natural conditions the following season.) Last year, and this also, we have adopted the plan of potting on the early forced plants from 4½-inch pots into 6-inch pots or from 6-inch pots into 8½-inch pots. In this way we have added considerably to our source of supply. Scarcely a plant missed showing one or two trusses; but, as we did not want the earliest, we pinched them out in order to get a later truss if possible. This season we have a good batch potted from 4½-inch pots into 6-inch pots, from which a good picking has been taken, and now we have this batch of plants as a whole, which will be the first plants to put in for early forcing this coming season. They are by far the strongest and best crowns we have, being much better than this season's runners. I see no reason whatever why this method should not be extensively adopted, especially of potting, from 4½-inch pots into 6-inch pots. *Royal Sovereign* is the variety I have treated in this way, and it is the second season of the experiment.—J. HUDSON in the *Journal of the Royal Horticultural Society*. Reprinted by permission.

DAFFODIL GROWING IN ENGLAND.

A COMING HOME INDUSTRY.

NOW that Daffodils have become so very low in price it behoves the cultivator to find the cheapest methods of growing them, always providing that the cheapest is also the best. When Daffodil flowers made from 1s. 6d. to 5s. per dozen bunches in the wholesale market the blooms would easily pay for the cultivation of the bulbs, but now the prices have dropped down to 9d. and even 5d. per dozen bunches, growers must leave no stone unturned if they are to see any profit; and the most economical methods must be used. One of the great labour-saving appliances is the plough. This was first used by some of the largest growers of the Daffodil as a cut flower. Mr. James Walker of Ham Common was the first one I saw employing it. Later on the Lincolnshire growers took it up with success. For a long time we held aloof from the plough, one difficulty in our case being the great number of varieties grown, but as our stock increased until it spread out into acres the necessity for some quicker method than hand labour forced itself upon us. Two years ago we bought a small one-horse plough, and after some little trouble in getting a start, for all new methods in nursery and farm work take a little time before they run smoothly, we found that it went both quickly and well. Given a good ploughman and a steady horse, the rows can be planted quite straight, and as regular a depth can be maintained as if planted by the spade. The growth of the bulb is also perfectly satisfactory. As to the saving of time, there is no doubt about that, since as much work can be done in a day with a given number of men and boys as the same number could do by spade labour in a fortnight. In our own case we this season planted some 250,000 bulbs in three days.

Bulb growing is becoming quite an industry in this country, and deserves the fullest support and encouragement, for there is no reason why a great deal of money which is now sent abroad for bulbs should not be kept at home; while here is another industry which will, when fully developed, help to bring the workmen back to the land, an end which many are now strenuously striving by word and deed to bring about.

J. DUNCAN PEARSON.

The Nurseries, Lowdham, Notts.

GARDENING OF THE WEEK.

FLOWER GARDEN.

SPRING BEDDING.

EXCEPT in the coldest parts of the country, many summer-flowering plants are still in great beauty. Begonias—both the tuberous-rooted and semper-florens sections and Lobelia cardinalis—again assert their superiority over the Geranium as all-round bedding plants. There has been no frost, and the rainfall, usually heavy in September and October, has been several inches below the average; but probably by the time these notes are in print we shall have had frosts of sufficient severity to render it necessary to clear off the beds and prepare them for the reception of spring bedding plants. In any case where the beds have to be so filled it is high time they were planted. Most bulbs deteriorate if kept unplanted after this month is out, and in the case of Wall-flowers, Silenes, and the many other plants used for spring displays, the earlier they can be planted the quicker they become established, and so better

able to withstand frosts. Where the beds are of sufficient size the use of dwarf shrubs—Retinosporas, Cupressus, Hollies, Aucubas, Euonymus, &c.—has much to recommend it. The bi-annual lifting tends to keep them dwarf, and with a little judicious pruning in the spring the same plants may be used for many years. When planting due care should be taken to do so firmly and to keep the specimen erect.

LIFTING AND STORING DAHLIAS.

After the foliage has been blackened by frosts the Dahlia tubers should be at once lifted, first cutting down the stems to about 7 inches or 8 inches from the ground. The tubers are very brittle, and should be lifted carefully. In a mixed collection see that the labels are securely attached. Place the tubers in their winter quarters with the stems downwards. After a few days they may be reversed and covered with dry soil. Such work as this should be reserved for wet days. Cannas should be treated somewhat similarly, except that they require rather more drying and to be stored in a slightly warmer place.

TUBEROUS BEGONIAS.

As a rule, the flower-stems and tubers part company after the first frost of any severity, but if

INDOOR GARDEN.

LESCHENAULTIA BILOBA MAJOR.

THERE are few more beautiful plants in flower during summer than this when it is well grown. It is not of easy culture, and from now until spring the greatest care and attention to watering should be given. Fresh air should on all occasions be freely admitted to the house, and keep the plants near the glass. Stimulants should not be too freely used as a means to encourage a robust growth, and in no case will their application be necessary during the dull winter months.

PITCHER PLANTS (NEPENTHES).

These are generally grown in baskets, and although the supply of water to the roots should be much reduced during winter, it will be necessary to syringe the baskets frequently to keep them moderately moist. As at this season they should not be encouraged to make growth, so the temperature should be lowered to 65° maximum, and a little air on favourable occasions will help to mature the growth.

SCHIZANTHUS.

Plants that have just been put into 3-inch pots, and the more forward into 5-inch pots, should be

PLANTING DAFFODILS BY THE ACRE: A BUSY SCENE AT MESSRS. J. R. PEARSON AND SONS' NURSERIES, LOWDHAM, NOTTS.

they do not separate easily it is best to lift them intact and lay them out in a cool, dry shed for a time. The tubers may ultimately be placed in boxes of dry soil or sand and be stored in a cool place.

LOBELIA CARDINALIS.

Many losses during the winter are due to coddling. The plants will withstand unhurt at least 20° of frost if planted closely on a south border and on the approach of severe frosts covered with a layer of leaves or Bracken. Where the frost exceeds the number of degrees stated, it would be wise to plant them thickly in boxes and winter in a frame.

Under these conditions air should be admitted as freely as possible, but drip is fatal. If the flower-beds are laid out in grass planks should be placed where there is to be any traffic, and as far as possible the work should be done on dry days.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

given full exposure to light, and afforded as much air as possible to keep the growth stocky and firm. The dwarf variety wisetonensis is best when grown singly in moderate-sized pots, but of the larger-growing pinnatus roseus, retusus, and candidissimus, three may be placed in larger pots; in this way extra large specimens can be grown. It is a mistake to force growth by the use of stimulants, as generally the plants grow strong enough in a good compost. When their pots are full of roots a dressing or two with Clay's Fertilizer, or the application of liquid made from sheep manure and soot, will help to keep them robust and healthy.

STREPTOCARPUS.

Plants that have just flowered are being placed in a dry cool house to rest until early spring. Afford them sufficient water only at the root to keep them healthy in the new year, when they should be started into growth, and with good treatment can be grown into fine specimens.

AUTUMN AND WINTER FLOWERING PLANTS

Among these are Cyclamens. More often than not these are placed in a close, warm house, and not only are the leaf-stalks then elongated and drawn, but the flower-stems also get drawn, and are unable to support the flowers properly. Place the plants near the glass with a maximum temperature of 55°, and on all occasions that are favourable admit abundance of air. These remarks will apply equally to Primulas, Mignonette, winter-flowering Geraniums, Tree Carnations, &c., all of which at this season will do best under the conditions above mentioned.

J. P. LEADETTER.

The Gardens, Tranby Croft, Hull.

FRUIT GARDEN.

FIGS.

THE earliest trees in pots, which were repotted or top-dressed as advised in a previous calendar and placed out of doors, should soon be prepared for forcing, and very little, if any, pruning will be required if the disbudding was properly attended to. If brown scale is troublesome the trees should be washed with a brush, using warm water, and adding 2oz. of carbolic soft soap to each gallon; take care not to injure the young fruits. When the trees are started make up a slight hot-bed of litter and leaves, and plunge the trees near the glass, with a night temperature of 50°, with a rise to 55° to 60° during the day with sun-heat.

RASPBERRIES.

If it is intended to make new plantations of these the ground should be prepared. Raspberries require a rich soil, and will occupy the same position for several years. The ground should be trenched 2 feet deep and a liberal quantity of half-decayed manure used, and with heavy soils vegetable refuse, wood ashes, leaf-mould, and road sweepings should be freely mixed. As soon as the soil has settled down and home-grown canes are at hand the planting should not be deferred. Choose medium-sized canes in preference to strong, succulent ones. The canes should be planted about 2 feet apart and 5 feet between the rows; spread out the roots carefully and make the soil firm around them; and defer topping the canes until spring. Well mulch the canes with litter before severe frosts set in. If the clearing of established quarters has been delayed, this should now be done, removing all old and weak canes, retaining only the strongest for future bearing. Tie up the canes loosely to prevent damage by strong winds, and afterwards give a liberal mulching of rich manure.

STRAWBERRIES.

Look over the beds and borders of recently set out plants and remove any late runners, lightly hoe the soil between the rows, and mulch with half-decayed manure.

BUSH FRUITS.

Preparation should be made for planting these. Red and White Currants generally shed their leaves first, and these should be commenced with and carried on whenever the weather is favourable. By planting in the autumn the bushes become established before spring, and the work can be better carried out than later, when the soil is wet and cold. They may be planted in an open position in well-drained soil about 5 feet apart, although a sheltered position may be selected with good results. Good varieties of Red are Fay's Prolific, Comet, and Ruby Castle. Versailles and White Grape are good white varieties. Planting Gooseberries and Black Currants should follow; the latter do well in a moist, shaded position. Gooseberries and Red and White Currants should be grown on clean stems, when no suckers will follow.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

ENDIVE.

It is now time for this vegetable to be placed under protection. A portion of the supply may be left for present use. This may be blanched by placing inverted flower-pots over the plants after they have been tied up. If the plants are put into frames they should be given a thorough watering, and the

leaves allowed to dry before placing on the lights. Several boxes should also be filled with plants, as they can be taken to the Mushroom house on short notice. If a quantity of plants still remain in the ground cover them with a frame as a safeguard against accidents.

HERBS.

If these are required green during the winter months lift them now and place in pots or boxes. Remove the top growth of Mint and lift several clumps into boxes, or they may be placed in heated frames. Give abundant air on all favourable occasions to prevent the growth being weak. Tarragon may be treated in the same fashion. A box of Chives is often useful during the winter months. Young healthy plants of Chervil may be grown in the same frame. Marjoram and Sweet Basil ought to be grown in pots and placed near to the glass in a cool house.

PARSLEY,

which is always in demand, should also receive attention, and wherever growing should be protected during severe frost. Plants may still be lifted and placed in cool frames. Keep them a good distance apart to prevent damping, and give plenty of air, except during severe frost. Cut down all herbs in the border and give a good top-dressing of short well-decayed manure.

SEAKALE.

If this is wanted early lift some roots, trim, and allow them to rest for a short time before placing in heat. For the earliest supply pots should be used 11 inches in diameter. Place six or eight roots in each pot, and place close to the pipes in the stove, or a small hotbed may be prepared for them. If no light-proof place sufficiently warm can be found for them the pots may be plunged in a large box, placing an inverted pot on the top of the full one, and covering the whole with a mat. This is a useful and common practice. The main supply should be left in the ground for some time, as in this district the plants are still green, though growth has stopped. Keep enough roots for new plantations, but not those that have been forced. They should be discarded. The straight and strongest pieces should be kept for cutting, and may be plunged in sand in a cool place till required in spring. A few roots of Rhubarb should also be lifted, but allowed to rest for some time before placing in heat.

*Hopton House Gardens,
South Queensferry, N.B.*

THOMAS HAY.

ORCHIDS.

PHALÆNOPSIS.

Now that light is becoming less day by day and evaporation is not so great, it is necessary to keep these much drier at the roots. When they have been potted in ordinary flower-pots very little water indeed will suffice. Any moss that has overgrown the centre of the plant should be removed. Pinch out all spikes as they appear on plants that have not made satisfactory growth. The atmosphere on all favourable days should be kept humid, and it is also essential to admit fresh air through the bottom ventilators.

EPIDENDRUM CILIARE.

When collar roots are emitted on plants that are well advanced in growth they should be repotted or resurfaced, using the same compost as advised for Cattleyas. Provide them with a light position in the intermediate house. When rooting freely they will take a fair amount of water; at other seasons very little water is required. This species is extremely interesting, and, being a good grower and flowering freely, it is well worth the room it occupies.

BRASSAVOLA DIGBYANA.

This plant should now be given a rest by withholding water. It will go for several weeks after the compost has become dry without shrivelling at this season. Afford them the lightest position possible during the winter months in the coolest part of the stove Orchid house.

ORCHIDS IN FLOWER.

Many beautiful Orchids are now in flower or about to flower, making the Orchid houses much

gayer than they have been since June. We are sometimes apt to maintain a show of flowers for a long season so as to interfere seriously with the future well-being of the plants by allowing the spikes to remain too long. Many of the Cypripediums and Cymbidium will carry their flowers for many weeks without any harm accruing if they are in robust health. But such free-flowering plants as *Lælia præstans*, *Cattleya labiata*, *Oncidium varicosum*, *O. Forbesi*, *Cattleya Harrisonæ*, and *Dendrobium Phalænopsis schroderianum* will, under favourable conditions, keep their flowers fresh for a much longer season than is good for the plants. In no case should the plant be allowed to become shrivelled through flowering, and I would advise the removal of the flower-buds as they appear on all plants that have not made good growth. Even if it is necessary to let them flower, much of the strain can be prevented if the flowers are cut off as soon as they are fully developed. At this season spotting of the flowers is often very troublesome. To prevent it raise plants in flower above the others, maintain a buoyant atmosphere by judicious ventilating and firing, and see that the glass of the houses is kept clean. On cold nights keep the house somewhat dry.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

POTATO NORTHERN STAR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It is always disappointing to have an idol shattered, but I question whether, generally speaking, Potato Northern Star is coming up to expectations. Of course, it had such a tremendous reputation to maintain that one felt rather sorry for it. In 1903 the demand was in excess of the supply at 20s. per pound; in the spring of this year Northern Star changed hands at from 2s. 6d. to 3s. 6d. per pound; and now the Potato may be said to be within reach of the non-speculative grower, but has it come up to expectations? Accounts appear from time to time of tremendous crops being lifted, but one hears a fair number of complaints as well, and, so far as being disease-resisting is concerned, the variety is no better than many others in this respect. The robust habit of the Potato is good in its way, but through it the plants are kept growing long after other varieties are ready for lifting, and this I consider is a drawback. A few weeks ago I saw Northern Star lifted in a trial of some thirty varieties, but it was easily beaten by Evergood, Dalmeny Beauty, The Factor, and several other sorts as regards weight of crop, and many of the tubers were tainted with disease. Indeed, I must confess to disappointment when Northern Star came out, for, though there were plenty of tubers, they were small and clung to the stem by means of thick, fleshy roots, which were far from being ripe. Perhaps the reputation of the variety has raised people to expect too much from it, but now it is in comparatively general cultivation it would be interesting to have the opinion of other readers of THE GARDEN as to the merits of the much-vaunted Northern Star.

G. H. H.

SINGLE DAHLIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Looking over my single Dahlias recently I could not help being struck with the beauty of many of the newer sorts Messrs. Cheal and Sons have sent out during the past few years. Although I have only between two and three dozen of the above, they have given me a quantity of flowers almost daily since the middle of August, and are at the present time covered with buds. For decorations they are almost unsurpassed, and a bowl or a vase filled with these small and beautifully coloured flowers at this season of the year is not to be despised. Mr. Crane, in his interesting notes, speaks truthfully of them as seen by him in Messrs.

Cheal's nurseries. I can only add the hope that next year may find more gardeners planting this variety, and that local and other Dahlia shows may more fully recognise the importance (as the National Rose Society is doing) of the value of decorative or garden varieties in their schedules. Among the many varied colourings two beautiful white singles are The Bride and Snowdrop, the former a grand flower, almost flat in shape, the latter rather smaller and reflexed. Beauty's Eye.—A lovely tone of mauve, flowering profusely. Miss Moreland.—A splendid deep rich crimson, and a grand flower. Naomi Tighe.—A dense sulphur-yellow. Hugo.—Scarlet, transfused with purple. Serita.—Very small, but well formed, of a plush crimson. Demon.—Quite the grandest of the dark colours, the deepest maroon, with a light band at margin of each petal, gold centre. Mrs. Henshaw.—A lovely primrose self. Columbine.—Very quaint. Puck.—Pretty in colour and form; and last of the few I name Irene and Nieta, two of the best bizzarres. With the grandest of all I have Etna, a colour most difficult to describe. May I add a few words on staking all Dahlia plants? I know the general rule is to drive a stake in the centre, regardless of the tubers and their subsequent growth. Why not take the trouble to put down three good stakes round the plant, and tie up the growth with good strong raffia or tarred twine, thereby allowing full freedom of growth of root and top.

CHARLES W. CROSBY, F.R.H.S.

Broome Hurst, Dorking.

THE DWARF POMEGRANATE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In any selection of plants suitable for a hot, low wall, such as that of a greenhouse, where the height is not sufficient to allow of the development of many popular wall plants, the dwarf Pomegranate is entitled to especial mention, for under such conditions it flowers freely and is always much admired. It is a dense twiggy bush, from 3 feet to 4 feet in height, and the flowers, which are single, are in the bud state of a bright red colour, but after expansion they are of a rich glowing orange tint. Towards the end of the summer it is, as a rule, freely laden with flowers, and in that stage it is delightful. Just before the leaves fall they change to a bright golden yellow, but do not remain long in that stage. According to London this dwarf form was introduced in 1723, but it is far less common than one might expect from its great merits if favourably situated. Given a sunny wall from 8 feet to 12 feet high the other varieties of Pomegranate do well thereon, and they frequently flower freely, especially if the summer has been a hot one.

H. P.

CHRYSANTHEMUM MAXIMUM KING EDWARD.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The illustration represents a fine type of *C. maximum*. It is certainly well described as "King amongst Marguerites." The growth is robust, the plant reaching 30 inches in height, and producing huge cupped flowers fully 6 inches across of the purest white. An award of merit was granted to it by the Royal Horticultural Society, and many first-class certificates have also been given to it. It is an ideal plant for the herbaceous border, and is grown extensively for market by the raiser, Mr. W. Angus, flower grower, Penicik, N.B.

T.

BROWALLIA SPECIOSA MAJOR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Few plants give us such a good bit of blue as this, and, what is more, it is a most continuous flowerer. We have some old plants that flowered throughout last winter; these were cut back a little in March to produce cuttings. As soon as we had our stock the old plants were shaken nearly free from old soil, repotted and replaced in gentle heat for two or three weeks, when they were again moved into the greenhouse, and here they have been laden with flower from early June. In fact, the plant acts similarly to *Begonia Gloire de Lorraine*, and can easily be had in bloom throughout the year with very little trouble. These old plants look as though

they would continue to flower throughout the coming winter, but now the young plants are opening their flowers there is no need to keep them, unless it is for a supply of seed, which is produced freely during summer under glass. I have saved a quantity, and intend trying this plant for bedding next summer. Probably it will require to be pegged, as the plant is inclined to become weak. If pegged and the growth pinched frequently while young I think the evil could be averted.

J. MAYNE.

AUTUMN-SOWN CAULIFLOWERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—We experienced the same difficulty with Cauliflower Autumn Giant sown the first week in September as did your correspondent "J. S. Higgins," though in a lesser degree, about 50 per cent. of our plants going blind. There were numbers of blind ones, too, among Early London, but not nearly so many. It cannot be said that our plants received any coddling, as they were pricked out 6 inches apart under east and west walls in the frame ground. Here they remained until they were planted out in trenches the first week in April. I have found, like Mr. Field, that with sowing early Cauliflowers in January under glass, especially those of the Snowball type, that a very large percentage of the plants button prematurely and are worthless. We generally make a sowing outdoors early in March, but none are so satisfactory as Autumn Giant, Early London, and King of Cauliflowers.

Bicton.

J. MAYNE.

RUDBECKIA MAXIMA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—It is rather cheering to learn from "G. B. M." that this Cone-flower is difficult to manage, for such is my experience in the cold, heavy soil here. I find a portion of the plant suddenly dies from no apparent reason, so much so that I had almost given up hope of being able to grow this charming border flower. I shall now replant it in a prepared site by adding a little drainage at the base and providing an artificial rooting medium consisting largely of gritty material. This and a mulching during the winter may reward me with success. I

lately saw this *Rudbeckia* growing in sandy soil, and with leaves 2 feet long.

Bishop's Waltham.

E. M.

MORE FRAGRANT CARNATIONS WANTED.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I noticed about three weeks ago that one of your correspondents complained that so few people are growing the garden and pot Carnations. It seems to me the reason is not far to seek. In striving for large blooms and variety in colours, the raisers have apparently overlooked the special charm of the Carnation, i.e., the perfume, which is absent in nearly all the new varieties. I wish you could get some correspondent to give a list of scented Carnations through the medium of your paper. It is impossible to tell from the raisers' catalogues which are scented and which are not.

T. W. HARRIS.

[We hope some one will help our correspondent.—Ed.]

NURSERY GARDENS.

DAHLIAS AT CRAWLEY, SUSSEX.

SINGLES.

THE name of Messrs. J. Cheal and Sons, Crawley, has so long been associated with all that concerns the welfare of the Dahlia, that a few remarks respecting their display this season may be welcomed by all interested in this autumn flower. The single-flowered kinds claim first attention. Messrs. Cheal are repeatedly cutting the blooms for various purposes, and in this way relieve the plants without apparently impairing their display. As a matter of fact, this is one of the secrets of successful culture of the single-flowered Dahlias. At Crawley the flowers are usually gathered when about two-thirds developed, and if they be straightway placed in a vessel of water they continue to open, and invariably remain fresh for four days. They should be gathered in the morning, quite early. Almost without exception the single-flowered ones are borne on stout, erect footstalks, this rendering them invaluable. A large area of the Dahlia

CHRYSANTHEMUM MAXIMUM KING EDWARD. (Much reduced.)

MESSRS. SUTTON AND SONS' LARGE FLOWERED PENTSTEMONS.

grounds is devoted to them, and from among the many good things there to be seen the following are specially noteworthy. Of the 1904 novelties Princess of Wales (soft pink, shaded mauve), Darkness (dark maroon-crimson), and Vesuvius (bright orange-scarlet) are excellent sorts. Snowdrop, raised by this firm, is the finest white single in cultivation. Serita is a good companion to the last-named, on account of its splendid form and rich crimson shaded purple colour. Other good and reliable sorts are Naomi Tighe (sulphur-yellow, with orange ring round disc), Formosa (rich crimson, with golden centre), Beauty's Eye (with crimson ring round disc), Leslie Seale (rich silvery lilac, with broad ring of deep crimson round the disc), and Miss Roberts (a lovely clear yellow). These are just a few of the better things.

POMPONS.

As garden plants the Pompon sorts excel, and in conjunction with the singles they were one of the bright features in the Crawley nursery. It is difficult to understand why these pretty little flowers are not more extensively cultivated. Many of them carried an immense crop of dainty blossoms. This type stands the weather well, and there is a continuous supply. For decorative uses, too, these smaller flowers are very serviceable. The Pompon Dahlias are seen to better advantage when grown on poor land. When planted in rich soil the flowers come larger than is desirable. Almost invariably the flowers are borne on stiff, erect flower-stalks, and for decorative purposes this is essential. Some of the best deserve special mention, *e.g.*, Darkest of All, certainly the darkest Pompon introduced to date; Elsa, introduced in 1903, a pure white, constant and free-flowering; Adelaide, a dainty flower, blush colour, edged with

lavender; Bacchus, still one of the brightest crimson-scarlet flowers in cultivation; Nerissa, beautiful soft rose, tinted with silver, the best of its colour; Demon, although inclined to be a little too big, is a splendid flower—its colour is deep rich crimson, shaded darker in the centre of the bloom; Tommy Keith (cardinal-red, tipped white), Montagne Wooten (white, edged with crimson), Violet (white), Little Bugler (rosy purple), and Ernest Harper (rich red). The 1903 novelty, Mephisto, is a good deep crimson-maroon, and is quite distinct. Adrienne is a flower of splendid shape; the colour is crimson-scarlet. The list of Pompons may well close with Burbank. This is a rich yellow flower, and the plant is very free-flowering and strong-growing.

SHOW AND FANCY DAHLIAS.

These were to be seen in infinite variety. The plants were well grown, and were bearing blooms of large size and good form. Even these heavy-looking flowers compared favourably with the majority of the Cactus-shaped blooms for decorative effect in the garden.

DECORATIVE DAHLIAS.

The decorative Dahlias are specially suited for garden embellishment, and at Crawley this type of the flower is not forgotten. From a florist's point of view the flowers may not be highly regarded, yet the free display, with their highly-coloured blooms, such as Cochineal (richest crimson), Countess of Pembroke (pale lilac), Black Prince (deep maroon), Maid of Kent (bright crimson, tipped white), Grand Duc Alexis (white), and Millie Scupham (golden bronze), have a charm for many.

TOM THUMB DAHLIAS.

There is still a demand for these dwarf bedding sorts, probably owing to their compact habit and continuity of flowering. As an edging to large and bold borders or edgings to beds they are still highly valued. The majority of the plants are about a foot high. The colours are pleasingly diverse. The Cactus Dahlias must be treated in a separate article, as there is so much to say about them, both from an exhibition and garden point of view.

D. B. C.

BEGONIAS AT READING.

AMONG the many flowers with which the name of Messrs. Sutton and Sons is inseparably linked may be mentioned the tuberous Begonia. The tuberous Begonia of to-day is a very different flower from that of ten years ago, and it is not too much to say that Messrs. Sutton and Sons have been closely associated with and are largely responsible for the marked improvement in form, colour, freedom of flowering, and vigour of growth shown by the latest productions of the Begonia hybridist. Now the Begonia is one of the most valuable plants the gardener can plant for the embellishment of the flower garden during summer and early autumn.

The shades of colour that may be obtained are innumerable, and some are so daintily and delightfully blended as to make a description impossible. There are reds and crimsons of the richest, yellows of the brightest, whites of the purest, roses of the rosiest, and probably one will soon be able to say blacks of the blackest. There is probably no other plant so beautiful in itself, and at the same time so useful for summer gardening, as the tuberous Begonia. The zonal Pelargonium and other bedding plants have to a large extent given way before its uninterrupted progress, and instead of the old riband borders of red, white, and blue we now see masses of Begonias, the large shapely flowers borne high on strong stalks, providing a continuous display of beautiful flowers in a great variety of colours from June to October, and thus giving the planter full value for his money at considerably less trouble.

In Messrs. Sutton's nursery at Reading several houses, which form part of the fine range of glass erected some two years ago, are full of tuberous Begonias, and quite recently they were making a grand display. You could not find a flower of bad form among them. They are all grown for seed only, and are the result of years of careful selection and skilled hybridisation. There were singles and doubles, fringed and crested, in some lovely shades of colour. The flowers were large and bold, held up by stout, vigorous stems, so that none were lost to view. All added to the display, and probably the reason of its being exceptionally good might be found in the fact that each flower was well displayed. The great fault of the tuberous Begonias of some years ago was that the flowers were produced on drooping stalks, and one of the chief aims of the hybridiser has been to strengthen these. How he has succeeded is well shown by the plants in Messrs. Sutton's collection.

In selecting a few varieties for special notice we should mention Sutton's Queen of the Whites, one of the finest single white Begonias yet raised. It is of elegant habit, the flowers are large, pure white, and of splendid form and substance. Giant Scarlet has enormous orange-scarlet flowers, and makes an excellent companion to Queen of the Whites. Rosy Queen bears rich ruby-rose flowers of good form, that may be relied upon to give satisfaction either in the greenhouse or out of doors. Then there are various shades of colour represented in the Reading Beauty strain, *e.g.*, crimson, scarlet, white, pink, yellow, blush, orange, &c. All these are single flowers of great beauty. Sutton's Fringed and Sutton's Crested will commend themselves to those who are fond of these forms. The former carry their flowers well above the foliage, and they are rendered still more attractive by the prettily fringed petals. The crested section comprises crested, bearded, and fringed flowers that give welcome variety; even those who do not care for their form can hardly fail to admire the colouring.

There are many beautiful things among the double Begonias also. Of fibrous-rooted sorts we may mention Miniature Bedding, a miniature sort which may be had in crimson, white, or pink. They are invaluable as an edging to beds or borders, for the flowers are produced in great profusion. Crimson Gem is the most attractive Begonia of the semperflorens type. Reading Snowflake has pure white flowers twice the size of those of semperflorens, while Fairy Queen is a charming little sort in pink and white; it comes quite true from seed, and flowers with great freedom in the open throughout summer and autumn.

There were many other interesting plants in flower in the Reading nurseries when we saw the Begonias, and among them the Pentstemons. Messrs. Sutton's large flowering varieties, of which we give an illustration, deserve special mention. The colours are pure and good, the result of careful selection, and they bloom throughout a long period. The large Gloxinia-shaped blooms range in colour through white, pink, rose, crimson, to mauve and purple. While writing of Pentstemons we might also draw attention to Sutton's Dwarf Blue as an attractive and useful little plant for a colour scheme in the herbaceous border. It is dwarf and perennial, bearing long spikes of bright blue flowers.

OBITUARY.

MR. FREDERICK G. LLOYD.

WE hear with great regret of the sudden death of Mr. Lloyd, Langley House, Langley. We well remember his interesting Rose garden and his work as a member of the council of the Royal Horticultural Society. Mr. Lloyd was a part proprietor of the *Daily Chronicle* Paper Mills, but we believe that of recent years his thoughts were centred upon horticulture, his work as an official of the Royal Horticultural Society and photography. Few men were better known or more highly respected in Buckinghamshire, as shown by the fact that Mr. Lloyd was High Sheriff of the County in the Coronation year and a Justice of the Peace.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THERE was a splendid show of shrubs, flowers, fruits, and vegetables at the Royal Horticultural Hall on Tuesday last, quite the best exhibition held there, with the exception of the fruit show. Awards were given to several new Orchids and other flowers, and to one new fruit. In the afternoon the Rev. Professor Henslow gave a lecture, illustrated by limelight views, upon "Geographical Botany as a Result of the Adaptability of Plants."

ORCHID COMMITTEE.

Present: Mr. H. Little (chairman), James O'Brien, de B. Crawshaw, H. M. Pollett, J. Wilson Potter, F. W. Ashton, W. Exall, W. H. Young, J. W. Odell, A. A. McBean, G. F. Moore, H. Ballantine, W. H. White, J. Charlesworth, J. Douglas, Walter Cobb, W. Bolton, F. Sander, W. A. Bilney, H. A. Tracy, Francis Wellesley, R. Brooman White, and F. J. Tignor.

The group from Messrs. Charlesworth and Co., Heaton, Bradford, was full of good things, and made an extremely attractive display. The most noticeable feature was a mass of *Cattleya Mantioli nobilior* (bowringiana \times aurea), a handsome flower of medium size, with deep rose-purple sepals and petals, and purple lip lined with gold. *Laelio-Cattleya Cappel* (L. cinoabarina \times C. gigas), with apricot-coloured sepals and petals and crimson lip, made a brilliant bit of colouring here and there, and so did *Cattleya Iris* (bicolor \times aurea), *Laelio-Cattleya callistoclossa*, and others. Among the many good plants we might specially mention L.-C. Ascania, *Miltunia Bleuana*, C. aurea, C. Fulvescens, C. F. W. Wigan, *Brasso-Laelia purpurato-digbyana*, *Brasso-Cattleya Warnerii-digbyana*, C. Germania (schoffeldiana \times hardyana), and C. labiata Lowie. *Vanda coerules*, bearing some rich blue racemes of flowers, was very beautiful. Gold medal.

Messrs. James Veitch and Sons, Limited, Chelsea, showed some beautiful *Laelias*, *Cattleyas*, and *Laelio-Cattleyas*. They comprised *Cattleya labiata*, C. Mantinii, C. Minerva, C. Mrs. J. W. Whiteley, *Laelia juvenilis*, *Laelio-Cattleya blechleyensis*, L.-C. Clonia, and L.-C. Lady Rothschild. *Cattleya Mantinii* (bowringiana \times dowiana var. aurea) is a beautiful flower, with rich rose-purple sepals and petals and purple lip, streaked in the centre with gold. *Odontoglossum grande* was well shown by Messrs. Veitch. Silver Flora medal.

Messrs. Sander and Sons, St. Albans, showed some very choice Orchids in their group. *Cattleya bowringiana* var. lilacina is very distinct and beautiful; it has deep lilac sepals and petals and lip, and the latter is tinged with violet. *Cattleya Mrs. J. W. Whiteley*, C. amabilis, C. F. W. Wigan, and *Laelio-Cattleya Herga* var. were some of the best hybrids shown. *Cypripedium Prince Humbert* (mestasiarum \times niveum) is a beautiful flower, the petals and lip deeply tinged with rose; and *Cynochos chlorochilon*, a remarkable one, the sepals and petals green, and the lip cream coloured. Among other good things were *Cypripedium Mme. de Curte magnificum*, C. Persephone, C. Rainbow, C. aureum var., and C. tessellatum (concolor \times barbatum). Silver Flora medal.

Mr. Cypher, Cheltenham, displayed a very bright group of Orchids in variety. *Dendrobium Phalaenopsis schroderianum* made a beautiful centre, and was flanked by *Cypripediums*, *Cattleyas*, &c. Among the *Cypripediums* were C. insignis, Sanderie, C. i. Perfection, C. Maudie, C. Mrs. W. Sutton, and others. *Cattleya Mantinii* was well shown, and so was C. labiata. *Dendrobium cobbianum*, *Cymbidium winniamum*, and *Cattleya schoffeldiana* were also in this group. Silver Flora medal.

Among the Orchids shown by Messrs. Hugh Low and Co., Enfield, were some good *Cattleya bowringiana* Low's variety, C. labiata, C. gaskelliana, C. Mantinii, and *Laelia pumila*. *Cattleya speciosissima*, C. Maronii, *Masdevallia tovarensis*, M. Pourbaixii, *Warszewiczella wailesiana*, and *Oncidium incurvum* album were other interesting ones in this group. Silver Banksian medal.

The Hon. W. Rothschild, Tring Park, Tring (gardener, Mr. Dye), exhibited a collection of *Masdevallias* and other small-flowered Orchids. Among the former were M. macrura, M. \times Fraseri, M. melanocantha, and M. coniculata. Other Orchids comprised *Laelia macrostachya*, *Bulbophyllum carryanum roseum*, *Phalaenopsis Lowi*, and *Orchidium Sophronitis*. Silver Banksian medal.

M. Ch. Vynsteke, Lochristi, near Ghent, exhibited some beautiful spotted *Odontoglossums*. They were chiefly forms of O. ardentissimum, O. bellatulum, and O. harry-crispum. Vote of thanks.

Messrs. Staeley and Co., Southgate, N., made an attractive display with *Cattleya labiata* var. autumnalis. The

flowers were large, of good colouring, and freely produced. Other *Cattleyas* included in the group were C. S. Gilles (Patrocinii \times aurea), C. wendlandiana var. superba, and C. Mary Gratrix (Harrisonae \times schoffeldiana). Silver Banksian medal.

The group of *Cattleya labiata* from Leopold de Rothschild, Esq., Gunnersbury Park (gardener, Mr. Reynolds), made a pretty display. There was considerable variety of colouring among the flowers, and some of the plants were splendid specimens, bearing quantities of blooms. Silver Banksian medal.

A small group of Orchids from J. Bradshaw, Esq., Southgate, N. (gardener, Mr. Whitelegge), contained *Cattleya labiata*, L.-C. Ascania, C. Iris, C. Mrs. J. W. Whiteley, *Miltunia Bleuana*, *Lycaste Skinneri* alba, and L. S. Fairy, all plants of much beauty. Silver Banksian medal.

Bulbophyllum Weddellii, shown by Mr. Moore, Botanic Gardens, Glasnevin, Dublin, was given a botanical certificate.

Mr. H. A. Tracy, Twickenham, showed fifteen plants in flower of *Cypripedium spicerianum* raised from seed.

NEW ORCHIDS.

Cypripedium F. K. Sander.—This is a handsome flower, the result of a cross between C. Annie Measures and C. bellatulum giganteum. The broad dorsal sepal and the large petals have a creamy white ground colour, which is heavily spotted with crimson. The spots are in places so numerous as to form irregular lines. The lip is long and pointed, white, with numerous small dots. From Messrs. Sander and Sons, St. Albans. First-class certificate.

Brasso-Cattleya Princess Victoria.—A large and most attractive flower, white, with a suffusion of green throughout, but least noticeable in the petals. The large lip is beautifully fringed, white at the margin and having a green throat, which is marked with green lines beneath the column. The parents of this hybrid are *Cattleya Mossie Wagneri* and *Brassavola digbyana*. From Messrs. Charlesworth and Co., Heaton, Bradford. First-class certificate.

THE LATE MR. FREDERICK G. LLOYD.

Cattleya Iris var. *Fascinator*.—This is a very handsome form of the hybrid *Cattleya Iris* (bicolor \times aurea). The sepals and petals are rich apricot coloured, while the margin is yellow. The flat lip has a yellow ground, which, however, is so heavily suffused with crimson as almost to be hidden. From Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

Cattleya Rosa Leemann.—A very beautiful flower, the result of a cross between *Cattleya amethystoglossa* and C. aurea. The broad spreading lip is richest purple, the sepals are dull yellow, dotted with purple, while the petals although of a similar shade are most beautifully suffused with purple, especially at the margins. From Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

Cypripedium King Edward VII.—A very handsome hybrid between C. rothschildianum and nites magnificum. Three flowers were borne on one stem by the plant exhibited. The dorsal sepal is heavily spotted with crimson-black upon a light green ground, against which it has a striking effect. The petals and lip are red-brown. From F. W. Wellesley, Esq., Westfield, Woking. Award of merit.

Cypripedium callistum Sander Hye's variety.—A very beautiful form of this valuable Orchid. The dorsal sepal has a pure white ground, and is heavily lined with green, and the petals are also lined with green. The association of white and green is most effective. The pouch is pale yellow. From Messrs. Sander and Sons, St. Albans. Award of merit.

Cattleya Portia Chardwar var.—A cut raceme was shown by Mr. G. F. Moore, Chardwar, Gloucester, but we were unable to find it.

FRUIT COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. J. Cheal, James Gibson, J. McIndoe, S. Murrell, Alex. Dean, W. Fyfe, H. Parr, P. C. M. Veitch, G. K. If, T. W. Bates, J. Lyne, J. Jaques, Oweo Thomas, G. Reynolds, F. Q. Lane,

J. Willard, George Woodward, James H. Veitch, George Wythes, W. Pompart, A. H. Pearson, and the Rev. W. Wilks.

An exhibit of fruit grown in British Columbia was shown by the Agent-General, Salisbury House, Finsbury Circus, E.C. The fruits had been packed for five weeks, and had travelled 3,000 miles by train and 3,000 miles by boat. On the whole they were firm and fresh, and their condition evidenced the careful packing they must have had. Among the best were *Bleuheim Orange* (finely coloured), *Vandervere*, *Northern Spy*, *Gravenstein*, *Wealthy*, and *Blue Pearmain*. Of Pears *Beurré Clairgeau*, B. Diel, and B. d'Anjou were excellent. A dish of Plum Grand Duke was exhibited. A very large and handsome Apple called Wolfe River was given a cultural commendation. In colour it resembles Hoary Morning. A gold medal was awarded to this exhibit.

Mr. E. Neal, gardener to J. A. Nix, Esq., Tilgate, Crawley, exhibited a good collection of Apples and Pears, the Apples being finely coloured. Tyler's Kernel, Cornish Gillyflower, Dutch Mignonne (very good), Allington Pippin, James Grieve, Ribston Pippin, Lady Sudeley, and Worcester Pearmain were the best of the dessert sorts, and among cooking varieties Chelmsford Wonder, Golden Noble, Ecklinville, Lord Derby, Tower of Glamis, and The Queo were best represented. The Nectarine Peach, Plums Reine Claude de Bayay and Coe's Golden Drop, and Pears Mme. Trevey, *Beurré Superfin*, *Beurré Bose*, *Doyenné Boussouche*, and *Doyenné du Comice* were excellent. Silver-gilt Knightian medal.

Mr. George Woodward, The Gardens, Barham Court, Maidstone, exhibited a grand display of hardy fruits, that commanded general admiration by their excellence. Kent is far-famed as a fruit-producing county, and the specimens shown by Mr. Woodward would have been hard to beat. It is useless almost to mention individual fruits when all the best known sorts were represented, but we thought Apples Tyler's Kernel and James Grieve particularly fine among this collection. Silver-gilt Knightian medal.

A collection of fruit was exhibited by the Horticultural Department of University College, Reading. Apple Peasgood's Nonsuch was very fine; Gascoyne's Scarlet was well coloured, though rather small; Ribston Pippin and *Bleuheim Orange* were very good; Pear Durondeau, Pitmaston Duchess, and Conference were also good.

Mr. W. Howe, gardener to Lady Tate, Streatham Common, showed six very good bunches of Alicante Grapes. The total weight of the six bunches was 20lb. Silver Knightian medal.

Mr. J. George, 14, Redgrave Road, Putney, showed Mushroom spawn.

Messrs. W. J. Brown, Stamford, exhibited a table filled with Apples and Pears, Roses, Pelargoniums, &c. Apples Peasgood's Nonsuch and Allington Pippin were very good, and the bunches of Roses were fresh.

Messrs. H. Cannell and Sons, Swanley, Kent, exhibited their Cabbage Cannell's Defence, and some fine bulbs of Onion Cranston's Excelsior. Silver Banksian medal.

Some very fine Pitmaston Duchess Pears were shown by F. Leverton Harris, Esq., M.P., Camilla Eacey, Dorking (gardener, Mr. McDonald). Cultural commendation.

Several seedling Apples were shown before this committee, but none of them obtained an award. The one thought most highly of was Ellison's Orange Pippin. This is a cross between Cox's Orange Pippin and Calville Blanc. As showing its remarkable fertility the Rev. C. C. Ellison, The Manse, Bracebridge, who raised and exhibited it, wrote that in 1899 he grafted seven trees of Holbert's Victoria with six Cox's Orange Pippin and one Ellison's Orange Pippin. In 1904 the six Cox's Orange produced three fruits and the one Ellison's Orange produced forty-eight fruits.

Another good Apple was H. Ballantine (Peasgood's Nonsuch \times Edmund's Pippin) from Messrs. James Veitch.

Mr. G. Wythes, Syon House Gardens, Brentford, showed a new late Melon of very good flavour, but no award was made.

The Horticultural Department of University College, Reading, exhibited an excellent collection of vegetables, neatly and effectively arranged. Mounds of Savoys, Brussels Sprouts, Cauliflower, and Celery formed a background, while Potatoes, Tomatoes, Carrots, Celeriac, &c., filled the front. Of varieties, Cauliflower Walcheren, Broccoli Veitch's Self-Protecting, Onion Sutton's Al, Potatoes King Edward VII., British Queen, Sir J. Llewelyn, Reading Russet, Evergood, Factor, and Tomato Polegate were of the best. Silver-gilt Knightian medal.

Mr. J. F. Williamson, Summerhill, Mallow, Cork, exhibited a good display of Potato Duchess of Cornwall, the variety famous for its large yield. Silver Banksian medal.

Messrs. Bakers, Wolverhampton, had a splendid display of Potatoes. One hundred varieties were represented, one basket of each being shown. Most of the new and sensational varieties were included, and good tubers of them were shown. The exhibit was attractively arranged, a matter that is not easy of achievement. Among the coloured varieties were Herd Baddie, Lord Peacock, Edgemoor Purple, Vicar of Laleham, Prizefighter, and others. Silver-gilt Knightian medal.

NEW FRUIT.

Bullace The Langley.—This fruit is the result of a cross between Damson The Farleigh and Plum Black Orleans. It is much larger than the Damson, purple, and with a good bloom. This will doubtless prove a most useful orchard fruit. From Messrs. James Veitch and Sons, Limited, Chelsea. First-class certificate.

FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), Messrs. H. B. May, James Walker, W. P. Thompson, E. H. Jenkins, James Hudson, J. Jennings, John Green, G. Renche, J. A. Nix, R. C. Notcutt, R. Hooper Pearson, George Nicholson, Charles Jeffries, C. Dixon, R. W. Wallace, H. J. Cuthbush, W. Cuthbertson, George Gordon, Charles E. Pearson, W. J. James, George Paul, Charles E. Shea, Charles Blick, C. J. Salter, W. Howe, and J. P. McLeod.

Mr. Norman Davis, Uckfield, set up a group of *Chrysanthemums* arranged in bold and striking manner. In the more prominent positions Miss Mildred Ware appeared to advantage, a dozen or more handsome flowers displaying

this sort perfectly. Other things of note were the white Japanese Mrs. C. Beckett, very fine; Marshal Oyama, bronze; Henry H., Miss Mona Davis, white, novelty for 1905; Afriston, crimson and gold, &c. Palms and Ferns were freely introduced in the arrangement. Silver-gilt Flora medal.

Messrs. T. S. Ware, Limited, Feltham, had a mixed group of hardy flowers, in which *Violas*, *Michaelmas Daisies*, *Delphiniums*, hardy *Cyclamens*, *Phloxes*, *Stuckesia cyanea*, *Phytolacca decandra*, the Japanese *Anemones*, such as *Whirlwind*, *Queen Charlotte*, and other like things were seen.

Mr. Godfrey, Exmouth, showed excellent examples of *Chrysanthemums*, notably *Triumph*, *Loveliness*, Mrs. J. P. Bryce, Mrs. George Nicholson, and the fine golden-yellow *Britannia*. Silver Banksian medal.

An extensive arrangement of hardy flowers was set up by Messrs. William Cutbush and Son, Highgate, in which *Michaelmas Daisies* in great variety played an important part. A new white, *White Bedder*, not a foot high, is a capital plant. Japanese *Anemones*, *Trifoliums*, *Colchicums*, *Montbretias*, the early-flowering *Chrysanthemums*, some beautiful *Aster Amelias*, fine pans of *Crocus zonatus*, and *Cimicifuga simplex* were also shown. Another group from this firm was of *Tree Carnations* in pots. Silver Flora medal.

Messrs. Peed and Sons, West Norwood, staged a very pretty group of *Chrysanthemums* on the floor, and with *Crotons* and *Palms* a good effect was secured.

Leopold de Rothschild, Esq., Gunnersbury House (gardener, Mr. Hudson), had a group almost entirely of yellow *Chrysanthemums* *soleil d'Octobre* and *Horace Martin*. Of the latter three giant specimens were shown, having a diameter of some 2 feet and simply smothered with blossoms. These splendid examples were in tubs. Silver-gilt Flora medal.

Messrs. J. Waterer and Son, Limited, Bagshot, Surrey, showed some sixty different shrubs, conifers, &c., plants of moderate size and general usefulness. The compactness of the plants left nothing to be desired. The rich colouring of the *Acers* was very fine. Bronze Flora medal.

Mr. H. B. May, Edmonton, had a very fine exhibit of *Crotons* in his varieties. Arranged on the floor with ample space the good colouring and general beauty of the plants commanded attention at a glance. Some of the newer sorts are *Elysian*, with twisted leaves; *Regalis*, drooping; Mrs. H. B. May, green and gold; *Silver Ring*, and *Golden Ring*. A basket of a new pink double-flowered *Pelargonium* C. T. Lawrence was also shown. Silver-gilt Flora medal.

Lady Tate, Streatham Common (gardener, Mr. Howe), contributed a group of *Crotons* of giant size, together with *Alocasias*, *Dracenas*, and other plants. *Callicarpa purpurea* was noted in fruit. Silver Banksian medal.

Mr. L. R. Russell, Richmond, filled a long table with *Aucuba vera*, *Skimmia japonica*, *S. fragrans*, *Pyraeantha Lelandi*, and other such plants. The variegated *Veronica Andersoni* was freely shown, and with *Fernettias* a good display of fruiting shrubs was made.

Messrs. William Ball and Sons, Chelsea, had a small and interesting exhibit of stove and greenhouse plants in variety.

H. J. Elwes, Esq., Colebourne (gardener, Mr. Walters) sent a charming lot of *Nerines*, of which two received the award of merit—Miss Shelley, pink, and Lady Folkes. Other notable things were *Miss Carrington*, *Princess of Wales*, *Countess Bathurst*, and *Miss Willmott*, scarlet. Silver Banksian medal.

A large assortment of cut shrubs was shown by Captain Holford, Tetbury (gardener, Mr. Chapman), in which *Oaks*, *Acers*, *Crataegus*, *Roses* in fruit, *Pernettyas*, *Rhus*, *Viburnums*, *Hippocrepis rhamnoides*, and many more were freely shown. The collection covered an entire table and received the Silver Flora medal.

Some good plants of *Amasonia punicea*, the pale yellow flowers and scarlet bracts very effective, were shown by Mr. Leopold de Rothschild, Gunnersbury.

Messrs. Gunn and Sons, Olton, Birmingham, had an extensive lot of early *Chrysanthemums* in which *Curie*, yellow; *Horace Martin*, *Roi des Blancs*, *Coral Queen*, *Goacher's Crimson*, *White Quintus*, *Meduse*, pale orange; *Ralph Curtis*, white, were shown among many more.

Messrs. Huzh Low and Co. had a small set of *Tree Carnations* and their new *Smilax*, *Medeola asparagusifolia* myrtifolia, a very fine leaved form, figured in THE GARDEN some months ago.

Mr. George Prince, Longworth, Berks, showed some beautiful *Roses*, e.g., *Frau K. Druschki*, *Pink Maman Cochet*, *Reve d'Or*, *Marie van Houtte*, *Papa Goutier*, *White Maman Cochet*, and *Corallina*. No group was more admired. Silver Flora medal.

Messrs. W. Wells and Co., Redhill, had a magnificent group of *Chrysanthemums* of all sections, many of the large-flowered kinds were especially noteworthy. Earlier and bush-grown plants were plentiful and well grown. The group was not only one of the most extensive but one of the best seen for a long time. A few of the best kinds were *Miss Elsie Fulton*, *Miss Mildred Ware* (rosy cerise), *Merstham Red*, Mrs. J. A. Miller (reddish terra-cotta, a massive flower), *W. A. Etherington* (silvery mauve), and Mrs. J. P. Bryce (a magnificent pure white). Of the incurving section of Japanese are some of the more prominent in a really wonderful lot. Gold medal.

Messrs. Dobbie and Co., Rothsay, staged a large collection of early-flowering varieties of *Chrysanthemums*, the group including all the best in commerce.

Messrs. Cannell and Sons, Swanley, contributed an excellent lot of zonal *Pelargoniums*, *Countess of Hopetoun*, *Lady Warwick*, *Prince of Orange*, *Queen of Italy*, *Mary Melton*, and Mrs. Simpson. Some good *Chrysanthemums* were also shown by the same firm. Silver Banksian medal.

Cut shrubs in variety came from Messrs. J. Cheal and Sons, Crawley, *Azaleas* and *Quercus coccinea* splendens being remarkable for the colouring. The *Golden Oak* (*Q. concordia*) was also in good form.

Messrs. Veitch and Sons, Chelsea, sent a splendid collection of *Nepenthes*. The plants were finely displayed and in per-

fect conditions. Some of the best were *N. Veitchi*, *N. mixta sanguinea*, *N. dicksoniana*, *N. wrigleyana*, *N. Curtisii* *superba*, and *N. Sir W. T. Thibault-Dyer*. *Bouvardias* in variety, beautifully grown: *Leonotis Leonurus*, with heads of orange-red flowers, and *Begonia Mrs. Deal* were all well shown in groups by the same firm. Gold medal.

Mr. Amos Perry, Winchmore Hill, had a fine group of *Senecio pulcher* and *Saxifraga Fortunei*, the latter not often seen in such good form.

Messrs. Barr and Sons, Covent Garden, had a small group of hardy plants in variety. *Aster Anellus* being conspicuous.

Messrs. Paul and Sons, Che-hunt, staged a fine group of *Roses*. *Papa Goutier*, *Sumise*, *Viscountess Folkestone*, *Frau K. Druschki*, *Corallina*, and *Caroline Testout* were all well shown. Silver Banksian medal.

Roses were well shown by Messrs. Frank Cant and Co., Colchester. *Corallina*, *Sulphurea*, *Marie van Houtte*, *Viscountess Folkestone*, *Maman Cochet*, *Mme. J. Dupuy*, *G. Nahomand*, *Gustave Regis*, *Safrano*, and *Sony*. de Catherine Guillot were among the best vases in a very beautiful lot of flowers. Silver Flora medal.

A primrose-yellow sport from *Market White Chrysanthemum* came from Mr. E. Wallace, Eaton Bray Nurseries, near Dunstable.

From Southampton Mr. Ladhams brought *Lobelias* and perpetual-flowering *Pinks* *Florence* and *Marion*.

Mr. John Jeffries, Cirencester, brought a small collection of choice conifers and shrubs, such genera as *Taxus*, *Abies*, *Cupressus*, *Ilex*, and others being freely represented. Silver Banksian medal.

A most imposing array of *Chrysanthemums* came from Mr. H. J. Jones, Lewisham, the arrangement consisting of large vases, epergnes, and large show boards. All of these were filled by show and other meritorious kinds, and were supported on each side by the more decorative sorts. *Henry Perkins*, reddish crimson; Mrs. J. Dunn, pure white; Mrs. R. C. Pulling; *Philip du Cros*, scarlet-red, tinted gold; *Maud du Cros*, yellow; Mrs. G. Judge; *Edith Smith*, creamy white; *Mary West*, yellow, shaded bronze, &c. Silver-gilt Banksian medal.

NEW PLANTS.

Nepenthes F. W. Moore.—Handsome and distinct. The rim of the medium-sized pitchers is rosy crimson and very striking. From Messrs. Veitch and Sons, Chelsea. First-class certificate.

Aconitum Wilsoni.—A very showy perennial, free, and profuse and continued flowering. The established plant is 5½ feet high, the blossoms blue. From Messrs. Veitch, Chelsea. Award of merit.

Nerine excellens major tardiflora.—A most distinct form, the flowers of which may almost be likened to a small-flowered *Belladonna Lily*, although the shade of colour is rather paler. The plant is 2 feet high, the blossoms borne on 3-inch pedicels and nearly horizontal, segments widely separated, and giving a diameter of more than 3 inches to each flower. From Messrs. R. Veitch and Sons, Exeter. Award of merit.

Rhus cilioides.—A fine-leaved plant for autumn effect. The broadly ovate leaves are entire and of a ruddy tone. Award of merit.

Coriaria terminalis.—Fruiting branches of this well-known plant were shown. The fruits are yellow, and of the size of a large Red Currant. The bunches of fruits are cylindrical in outline and about 4 inches long, and, depending on slender branches, render the plant most attractive at this season. Award of merit. Each of these were shown by Messrs. R. Veitch and Son, Exeter.

Begonia Fearnley Sanders and *Begonia Mrs. H. G. Moon* are two of those beautiful hybrids, having *B. bowringiana* and *B. Rex* variety as their parents. Olive green, red, and maroon predominate in markings of the handsome leaves. These were from Messrs. Saider and Co., St. Albans, and each received an award of merit.

Nerine Lady Folkes.—A rather dwarf sort, with flowers of a deep rich carmine. Very striking and effective.

Nerine Miss Shelley.—In stature and other ways this much resembles the *Fothergilli* section; it may be said to be a pink-flowered form of it. The tone of colour is very pleasing. These were from Mr. H. J. Elwes, Cirencester, and each obtained an award of merit.

Holanthus sparsifolia.—This is stated to be a hybrid between *H. rigidus* and *H. californicus*, the blossoms resembling the former, and the foliage to some extent the latter. It is a tall growing and effective plant. From Messrs. Cannell and Sons, Swanley. Award of merit.

Sternbergia lutea major.—It is curious when we remember how often this plant has been shown, and in much better condition than on the present occasion, that the award it so well merited has been so long in coming. In its best form it is one of the finest of autumn bulbous plants, and the glistening golden cups are most effective. From Messrs. Barr and Sons, Covent Garden. Award of merit.

Chrysanthemum Mrs. D. W. Jones.—This is a Japanese incurved, chestnut terra-cotta, with old gold reverse, one of the brightest in this shade; flowers of large size and finely formed.

C. E. J. Brooks.—A Japanese incurved, rich plum colour, with white reverse; a monster flower as round as a ball, foliage and stems splendid.

C. Mrs. William Knox.—Rich deep yellow, with a faint tinge of bronze; said to be most easy of cultivation, developing well under quite ordinary treatment.

C. Goacher's Pink belongs to the early-flowering section, and may be described as an advance upon those of its shade now grown.

C. Jenny, also an early flowering kind, but of the Pompon class, with round, perfectly formed flowers of a bright orange shade. These five kinds were from Messrs. W. Wells and Co., Redhill, and each received an award of merit.

C. Mrs. Chas. Beckett.—There is certainly an ample supply of pure white kinds, but there must ever be room for such a magnificent thing as this. Purest white, broad drooping flowers, and a massive head that compels admiration. From Mr. N. Davis, Framfield. Award of merit.

C. *Pearly Rose*.—A very free-flowering September kind with perfect habit. From Messrs. Cannell and Sons, Swanley. Award of merit.

C. *Miss Dorothy Oliver*.—A reflexing Japanese of the largest size, the petals broad, and of a bluish or lilac-purple tone. From Mr. G. Mileham, Leatherhead. Award of merit.

C. *Edith Smith*.—A creamy white Japanese, the shapely broad-shouldered flower of large size and very striking. A very handsome variety. From Mr. H. J. Jones, Lewisham. Award of merit.

DUSSELDORF INTERNATIONAL FRUIT SHOW.

OF the series of shows in connexion with the Dusseldorf Fine Art and Horticultural Exhibition, the International Fruit Show, held on October 16 to 19, is important. Tons of Apples and Pears in good condition filled eight of the spacious buildings, but the Grapes were not proportionately good. The idea of the Pomological Society was to call together from all parts of the Empire not only gardeners and fruit growers, but fruit farmers, foresters, and heads of provincial fruit societies, and by a series of lectures, comparison of notes, and exhibits to find out what can be produced, and to give a greater stimulus to fruit growing in every branch. The one class that interested me most was that of provincial collections of Apples and Pears grown on standards, for planting at the sides of highways or divisions of fields. This way of utilising waste spaces has been the chief hobby of the various great agriculturists and horticulturists for the last twenty years, and has grown until it has become a part of a great national industry. The finest collections in this class came from the "Highlands of Westerwald" (Hessen) and "Land Kreis Wiesbaden." Most of the horticultural schools were represented, that of "Geisenheim a Rhein" having a very fine collection of fruit with arrangement of plants, &c.

At the end of the building was a very imposing group of Apple trees in pots from the Imperial Gardens at Potsdam, chiefly *Calville Blanc*, of which some thousands are grown. Single dishes were staged in great quantities. *Gravensteiner* 250 times, and *Winter Gold* Pearmain 180 times, will give an idea what difficult work the judges had before them. In the international division, the pavilion was given over entirely to the Austrian Tyrol and Bohemia, and from there were staged many perfect fruits in the single dishes and packed for market; the same finish was maintained throughout. The Swiss fruits were also very fine, being packed in baskets of green and white wicker-work, which produced a very pleasant effect.

The large flower palace was chiefly devoted to the exhibits from France and Holland. In the entrance a large wedge-shaped table was filled with a floral and fruit display by M. Joret of Paris, including Apples, Pears, and Peaches in the finest condition. An exhibit that attracted most attention was from A. Cordonnier et fils, Grapperies du Nord, Ballicul, North France. Under massive glass cases was a splendid collection of Grapes—excellent bunches of *Cannon Hall Muscat*, *Muscat of Alexandria*, *Alicante*, and *Gros Colmar*, and an interesting group of ten new seedlings. *Buckland Sweetwater X Alicante* had a distinct blue shimmer in the yellow, which is not very tempting, but it may result in a good flavour and thin skin.

The best collection of Apples and Pears in the whole show was exhibited by the Horticultural Society of Montreuil-sous-Bois. It consisted of about 150 dishes, and covered at least 70 yards of space. Semi-circular stands were used as a background, a few Cyclamen helping to take off the formality and give variety in colour. Two large tables were filled with an exhibit of Grapes and Peaches from the Netherland Union of Grape Growers, Westlandia. They were chiefly *Alicante* and *Colmar*. The bunches were not large, but the quantity had an imposing effect. Prizes were given for packing Grapes, Messrs. Salomon et fils, Thomery, staging large quantities, chiefly *Chasselas Doré*. I thought it rather a pity that English firms were not among the competitors, but, as a member of the committee remarked, "You Englishmen only go where you can make business."

E. W. G.

KIDDERMINSTER HORTICULTURAL SOCIETY.

THE following is the annual report of this excellent society: "In presenting the sixth annual report and balance sheet of the Kidderminster and District Horticultural Society, it is with much pleasure and satisfaction that we are able again to record the substantial success of our society, both numerically and financially, our total membership being now about 250. The committee are also pleased to report a most successful year's work, and feel confident that during the past session much has been accomplished in the way of fostering and encouraging an interest in the various branches of horticulture in the town and district. The lectures given have been of a specially attractive and instructive character, and have been very well attended. Four shows, in addition to the annual *Chrysanthemum* show (the arrangements for which have been taken over by the society), have been held during the year, which have done much to stimulate practical work among the members, and at the same time have afforded a source of instruction and pleasure to a considerable number of appreciative visitors. The exhibits at all the shows have been of a very high order of merit. Visits have been paid during the year to the gardens of Madresfield Court, by kind permission of Earl Beauchamp; also to the gardens of Impney, by kind permission of Dr. Corbett; and these were in each case much appreciated by a considerable number of visitors and friends. With the object of beautifying and relieving the sombre appearance of our streets, prizes have been offered in a competition for the best floral window display during the summer. The matter, however, was not taken up by the residents to the extent the committee hoped for; they trust more interest may be shown in this laudable object in future. The report is signed by H. de B. Gibbins, Litt. D. (chairman), and William C. Sadler (secretary). The balance at the bank is nearly £30.

THE GARDEN

No. 1719.—VOL. LXVI.

[OCTOBER 29, 1904.]

ROSEMARY.

FROM a certain vantage point in our garden an opening in the Rhododendrons discovers an exquisite glimpse of meadow-land and wood, with here and there a red-roofed homestead, and beyond a goodly stretch of the changeful sea. In and out amongst the pastures winds a road which we, who know it, can trace by its bordering hedgerows, but now and again the sandy highway to the sea shows bright and clear against the greenery, and gives a touch of human interest to the scene. Locally this road goes by the name of Rosemary Lane—it is even to be found so named in the Ordnance maps—yet it is not associated, in any apparent way, with our garden Rosemary, whose name is almost as much of a riddle as that of our lane. Going back to derivation, however, we get an interesting side-light of meaning.

Rosemary is one of the oldest of our garden shrubs, but it is not native-born. Its home was on the sunny sea-board of the Mediterranean, and it was carried thence to our shores—probably as physic merchandise—in very early times. But in those days Rosemary was known as Rosmarine, or, in old French, Romarin. It may be found so-called in English literature of the fourteenth century—Rosmarine, the bush of the sea-spray. And so we may be forgiven if we link our pretty road to the same name-germ, and think of it as the lane of the sea-dew, while we watch, as often we may, the warm sea mist sweeping across the flats or wrapping the uplands in the fleecy clouds of dew which help to keep our countryside green and flowery long after autumn frosts, further inland, have mown down the late summer laggards.

But in process of time the word was clipped, as such words often become in familiar speech, and the final letters dropped away, leaving it Rosmari. And then, later on, popular sentiment stepped in, and—either on account of the incense breath of its leafage or the hue of its blue flowers, the Virgin's colour—dedicated the shrub, as so many other plants in those days were dedicated, and it became Rosemary, as it remains to this day. In truth, it has no more to do with a Rose than the rose of a watering-pot, which has the same name-root. Yet even as it stands dedicated to-day Rosemary dates back for many a century, nor does it seem any longer to crave the sea-spray for its well-doing, for—albeit a little tender in a

severe winter—it thrives in inland gardens just as well as by the sea. No English garden, indeed, ought to be without Rosemary. It is rooted in our history and in our literature, no less than in the rural customs of our everyday life. Tradition has it that Anne of Cleves, staking her life on a poor venture, wore sprigs of Rosemary in her wedding posy. The only luck it brought her, maybe, was to call to remembrance the strength of protecting and powerful friends which secured to her a safe asylum at Richmond instead of the fateful block on Tower Green. At any rate, here is direct evidence of the existence of an ancient custom. Two faithful virtues, constancy to the living and remembrance of the lost, have always been close entwined about the Rosemary branch which in the West Country we still

"Grow for two ends, it matters not at all
Be 't for my bridall or my buriall."

Rosemary is somewhat tender, as we know, but if a seed, for it comes far better from seed than from cuttings, can be coaxed to root into a crevice of an old sunny wall, it will wax strong and hardy, and no prettier way of growing it can be found than to let it shape itself, as it will by its own device. It likes the lime of the old mortar, and is far more aromatic in such scant harbourage as it can find for itself than when given the luxury of richer soil, but it must have sunshine.

Sometimes Rosemary may be seen covering the gable end of a cottage to the very eaves for with a little care and training it will reach a height of 15 feet or more. And then how the bees revel in the grey-blue flowers on a bright morning in early spring. For that reason alone bee-keepers do well to grow plenty of it for the excellent flavour which it will give to their honey.

We have seen in a country garden a simple archway made of rough Oak boughs clothed with Rosemary, which seemed a charming way of disposing it, but many a pretty idea can be carried out in a sheltered cottage plot which we fail to find answer when we come to try it in more spacious surroundings. In some way or other, however, we must find room for this good old bush, and it should be placed, not in some neglected out-of-the-way corner, but where it can be seen and approved. It is quite as appropriate for the stately terrace balustrade as amongst the herbs of the kitchen garden, or trained against a farmhouse porch. So have it we must, whether our lot be cast in castle or cot. For we miss some undertone of that hidden poetry of life which vibrates

through the common air we breathe, if we cannot, now and then, throw a Rosemary branch into the fire and let its fragrance awaken tender memories of the past, and even to stir within us nobler thoughts than we are wont to have of the faith and loyalty which wearies never, though Time steps on.

THE AUTUMN.

As I write the end of October is in sight, and yet after a touch of frost in the morning the day is bright and summer-like and the roads hard and dry. Indeed, it is some years since so fine a summer was followed by such a delightful October, and both gardeners and farmers have good reason to be thankful. Never perhaps have the autumn tints been more beautiful. Was there ever a finer autumn for flowers? I question it, for though in some places frost has blackened the Dahlias and nipped delicate plants, there is still an abundance of blossom, and the season of what are strictly speaking summer-flowering plants has been considerably increased. We still have Roses in abundance, and it is a pleasure on an October morning to be able to pick a velvety Prince Camille de Rohan or some other variety as perfect in form, if a little wanting in scent, as any of the blooms which came in July. While one section of the Chrysanthemum-loving community is interested in giant blooms for the November shows, another is enjoying the feast of flowers in the garden, for the Chrysanthemum outdoors has behaved admirably this autumn, and many a wayside garden is gay with varieties which were once favourites in the exhibition world.

Most of the hardy fruit has been gathered now, and this work has added much to the labour item during the past few weeks, but the weather has not only been admirable for ripening the fruits and imparting rich colour and high flavour, but owing to the absence of storms of wind most of the Apples and Pears hung on the trees till they were picked by hand. Considering the way trees in orchards and gardens were laden, there have been very few windfalls, and most of the fruits which fell to the ground were bored by the maggot of the codlin moth. On the other hand, wasps were a plague amongst the early fruits, while birds have also given trouble, and the worst of it is they always seem to select the finest specimens for their depredations. The trees, as well as the fruit, have benefited by the autumn sunshine, as may be observed by the healthy, ripe nature of the young wood, and the plump, prominent appearance of the fruit-buds. If these signs are anything to go by, Nature has done all she can not only to give a bountiful harvest this year, but to ensure a healthy promise for next.

Turning to the kitchen garden, conditions are equally satisfactory, for whereas last year

one had to wait week after week for a dry spell to lift the main crop Potatoes while the tubers were rotting wholesale in the ground, this season they have come out clean and dry, and if not entirely free from disease the losses through this evil are by no means great. Much disappointment was caused last winter through Onions failing to keep, but I look for no repetition of the trouble, as the autumn sunshine ripened up the bulbs on the ground, and harvesting was no matter for anxiety. Root vegetables have done well, and the quality of Carrots, Parsnips, and Beet is excellent, while in every garden almost there is a good supply of winter greens. Runner Beans are scarcely over, and those who took the trouble to trench deeply and manure liberally for their Peas have been rewarded with good late dishes. Lastly, the Tomato has proved a satisfactory outdoor crop when climatic conditions are favourable, for this plant has revelled in the sunshine, and even late fruits which we had little hope for ripened up on the stems.

Indeed, taking the kitchen garden from end to end, there is not much to complain about, and the fine autumn weather is favourable for lifting and storing crops, cleaning up, and putting things in order. Those who are anxious to be moving fruit trees and shrubs would like to see some rain now, as the ground is dry for the time of year, but on the other hand the open autumn is excellent for pushing on with the alterations which take place in many gardens at this season.

Finally, the splendid autumn weather is, to use a common expression, helping on the winter, which is always long and dreary enough, but when what is practically summer extends to November, some of the sting is taken out of the dull season which follows.

G. H. H.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

November 1.—Bournemouth Chrysanthemum Show (two days); Brighton Chrysanthemum Show (two days); Royal Horticultural Society's Show.

November 2.—National Chrysanthemum Society's Show at Crystal Palace (three days); Southampton Royal Horticultural Society's Show (two days); Highgate Chrysanthemum Show (three days); Lowestoft Chrysanthemum Show (two days); Portsmouth Chrysanthemum Show (three days).

November 3.—Weybridge Chrysanthemum Show; Colchester Chrysanthemum Show; Forest Gate Chrysanthemum Show (three days).

November 4.—Windsor and Eton Chrysanthemum Show; Battersea, Clapham, and Wandsworth Chrysanthemum Show (two days); Hinchley Chrysanthemum Show (two days).

November 5.—Batley and District Chrysanthemum Show; Loughborough Chrysanthemum Show; Penarth Chrysanthemum Show; North Lonsdale Chrysanthemum Show.

November 8.—Ipswich and East of England Horticultural Society's Show at Ipswich (two days); Dulwich Chrysanthemum Show (two days); Sevenoaks Chrysanthemum Show (two days).

November 9.—Buxton Chrysanthemum Show; Southend Chrysanthemum Show (two days); Stoke Newington Chrysanthemum Show (two days).

November 16.—Liverpool Horticultural Association Chrysanthemum and Fruit Show (two days).

November 17 and 18.—Grimsby Chrysanthemum and Fruit Society.

November 23.—Annual Dinner of the National Chrysanthemum Society, Mr. C. E. Shea in the chair.

"The Garden."—The next number of THE GARDEN will be largely devoted to matters of special interest to fruit growers. There will be

illustrations and descriptions of new fruits, famous fruit gardens, and a feature will be the selections of fruits for different purposes, e.g., for small gardens, large gardens, orchards, &c.

Royal Horticultural Society.—At the next meeting of this society, on Tuesday next, the Hon. Vicary Gibbs has kindly promised to lecture on "Planting for Winter Effect," and it is hoped that those who can will make exhibits of any plants bearing on the subject of the lecture.

The French National Chrysanthemum Society will hold its annual show and conference at Montpellier, on the 29th inst. and following days. There are eight items on the agenda, mostly dealing with manures, sports, carriage of plants and blooms to exhibitions, sterilisation of soil for Chrysanthemums, insects, and the proposed colour chart. Other Chrysanthemum shows in France will be held at Paris, Lyons, Le Mans, Elbouf, Fontainebleau, Besançon, Limoges, Amiens, Cherbourg, Havre, Troyes, Armentières, &c., several of which are by societies affiliated to the French National Chrysanthemum Society.

Chrysanthemum sports.—Why is a plant sport difficult to explain? A week or two since I observed in a trade paper an enquiry from a market grower respecting the reason why nearly one-half of his stock of the golden-yellow Horace Martin (a sport from Marie Masse) had produced pink flowers. The season previous his stock of several hundred plants was quite true. He planted this season 2,000 with the above result. A large number of growers will be sadly disappointed over the sport of Mrs. Barkley, sent out as Lady Cranston. The white flowered sport appeared in 1902, and the stock last season was eight plants, all true to the sport. The form of the flower was entirely changed, and the colour was pure white, prettily, but slightly, flushed on the crown (not the centre) with clear rose-pink. It was certificated by the National Chrysanthemum Society and the Royal Horticultural Society's floral committee, and was awarded the silver medal by the Scottish Horticultural Society as the best novelty. All who saw the blooms were charmed with them, and there was a keen competition for the stock. But, alas! the whole stock seems to have reverted to the original Mrs. Barkley, for out of about one hundred very fine plants not a white flower has appeared, and other growers complain of the same thing. It is much to be regretted.—P.

Belladonna Lily at Fortfield House, Terenure, County Dublin.—

The place selected here for the cultivation of this beautiful Lily is a warm border at the foot of a south-east wall, the dry season and position apparently just suiting it. An unusual quantity of flower spikes have appeared, and at a season when they are most desired. Introduced as they were from the West Indies into British gardens as far back as 1712, they are still unsurpassed for delicacy of tint and fragrance. Since their introduction some new forms have appeared, one being called the Kew variety. This has a large deep pink flower and broad foliage; it is one of the best.—S. BRYAN.

Tufted Pansies in October.—Tufted Pansies have been flowering profusely during the last few weeks. The hot and dry weather during the past summer tested the plants severely, and at one time they were in a very bad way. Fortunately, the welcome rains came just in time to save them, and in consequence they quickly regained their former vigour. During the latter part of August and September the display was well maintained, and the older growths being cut out the plants appeared to take a new lease of life. For the past ten days there has been quite a blaze of colour in the beds and borders devoted to these flowers, and at no period during the present year have the plants looked better. Those that were cut back in August are also making a brave show. Among the yellow sorts Mrs. E. A. Cade has been superb, its large and attractive rayless yellow blossoms standing out distinctly. Yellow Beauty, Yellow Glory, and Yellow King are three sorts that also deserve special mention for their fine effect when massed. White

sorts are represented by the rayless Swan and Seagull. Of blue varieties Jackdaw, Blue Tit, Ophelia, and John Shires are among the best. Mauve-tinted kinds are useful for association with the blue varieties, and of these Marion Waters, Florizel, and Janet are excellent. These are grown within six miles of London, and succeed well.—D. B. CRANE.

Pentstemon Lord Charles Hope.—

This new Pentstemon, which received a certificate at the October meeting of the Scottish Horticultural Association, is evidently a great acquisition, and likely to prove one of the most valuable of its colour, either for bedding or the mixed border. It is a seedling, raised by Mr. T. Hay, gardener to the Marquis of Linlithgow, at Hopetoun House, South Queensferry, and it has proved so satisfactory there that Mr. Hay brought it before the Scottish Horticultural Association. It will be sought for by those who desire a bright scarlet Pentstemon of dwarf habit and of such a character that it does not require sticks. The flower is quite brilliant in its scarlet colouring, and the plant grows about 18 inches high. The flowers are large, though not so large as in some Pentstemons, and they are produced in large numbers. As Mr. Hay informs me, it is quite distinct from any other at Hopetoun, where over 2,000 Pentstemons are grown. Some spikes have as many as eighty flowers thickly set upon them, and yet not so closely as to be stiff-looking. I have been much pleased with this Pentstemon, some good spikes of which are before me as I write.—S. ARNOTT.

British Flowers at the St. Louis Exhibition.—We are pleased to note that Messrs. Sutton and Sons of Reading have been awarded by the jurors of the St. Louis Exhibition the "Grand Prix" for their collection of bulbous and annual flowering plants. This is the only "Grand Prix" awarded for flowers in the British section. In addition Messrs. Sutton receive the only gold medal given in this section for grass seeds. The bowling-green and the various lawns sown down with Sutton's lawn seeds were much admired.

Protection of alpine flowers.—No. 19 of the "Communications of the German and Austrian Alpine Club" contains the following note: "Protection to alpine plants, giving sequence to the precedent of the administration of other countries, re the protection and preservation of the Edelweiss." The Nether-Austrian Landtag has, in the year 1901, prohibited, under penalties, the pulling up by the roots, and the offering for sale of such plants with their roots. The presidency of the society for promoting the increase of travelling visitors to Nether-Austria have now presented a memorial to the board of councillors, praying that the benefits of such protection may similarly be extended to other alpine and sub-alpine flowers and plants. The board of councillors have not opposed these considerations, and have now, through their reporting member, Dr. Schleicher, presented to the Landtag the following Bill, which will be sure to be welcomed by all lovers of Nature: "With regard to the following plants, viz. (a) the Kohlröschen (*Nigritella angustifolia*), (b) the Franonshuh (*Cypripedium Calceolus*), (c) the Aurikel (*Primula Auricula*), (d) the Stengellose Enzian (*Gentiana acaulis*), (e) the species of *Kervensengel* (*Ophris*), lifting or pulling up plants with roots and tubers is prohibited, also the offering for sale of such plants which are furnished with roots and tubers. With regard to the plant mentioned (sub a), viz. (*Kohlröschen Nigritella angustifolia*), the trade, also with plants minus their roots, is not conceded. Only such cases form an exception to this decree where the collecting of these plants serves a scientific purpose. In this case, however, permission must be obtained from the political authority of the district. Offences against this enactment will be punished by the political authorities with fines of from 2 kronen to 20 kronen, and in cases of repetition of 50 kronen, these penalties to go to the poor fund of the particular parish within the boundaries of which the offender had been taken up. It is also decreed that the plants shall be confiscated.—E. HEINRICH.

Buddleia variabilis veitchiana.—I lately saw this Buddleia growing at the foot of a wood fence in the garden at Westwick Hall, near Norwich, where it was flowering well. It is a grand plant for training loosely to a fence. The large, deep green leaves quickly cover space, and the purple racemes are very showy.—E. M.

Myrtus apiculata (M. Luma).—How much superior is this Chilean Myrtle to *M. communis*. While the flowers of the latter are a dull white those of *M. apiculata* are snow white, and are produced much more freely than in the case of the common form. The foliage, too, is a deeper green.—E. M.

Solanum jasminoides.—Growing over the southern side of the porch of Mr. Herbert Reeves's house, Northlands, Emsworth, near Havant, is the finest out of door specimen of this South American *Solanum* that I have seen. The plant was put out eight years since, and only receives slight protection at its base during the winter. The plant is about 15 feet high, with luxuriant foliage; it is quite smothered with the pure white blossoms, which are exceptionally large. Last spring the plant was pruned back to the old wood, thus inciting it to make new growth. Seen as this plant is now, one cannot fail to recommend its use wherever a south wall is available.—E. M.

British Columbian fruit.—Only a few years ago British Columbia was regarded as a good country for timber, minerals, and fish, and practically nothing else, but now it is found to be one of the best countries in the world for the production of fine fruit, and fruit-growing is rapidly going ahead, with good profits to the growers. Some of this year's growth of Apples and Plums that have just arrived in London were shown on Tuesday, the 18th inst., at the Royal Horticultural Society's new hall, Vincent Square, Westminster, and awarded a gold medal.

The Royal Dutch Bulb Growers' Society, Haarlem, Holland, intends to hold its quinquennial exhibition of bulbous flowers on March 17—21, 1905. The schedule, which has just been published, shows that a large number of prizes are being offered. It is intended to make this show the finest that has been held by the society. Those interested can have further particulars on application to the secretary, Mr. Joh. de Brenk, Haarlem, Holland.

Tacsonia mixta.—I once heard exception taken to the brilliantly coloured *Tacsonia Van Volxemii* on the ground that it was too gorgeous to harmonise with its surroundings, though I think few would be found to endorse that opinion. In any case the same charge could not be brought against *Tacsonia mixta*, whose flowers are of a delightful shade of soft pink, and on a large and old-established plant they are borne in great profusion. It resembles *T. mollissima*; the flower has a similar long tube, but the larger flowers of *T. mixta* render it more showy. A fine specimen has been flowering for some time in the Temperate house at Kew. Both these species are natives of the Andean region of South America. In the "Kew Hand List" *T. eriantha* is regarded as synonymous with *T. mixta*.—T.

Euonymus alatus.—Among the cut branches of shrubs exhibited by Mr. Chapman, gardener to Captain Holford, Westonbirt, Tetbury, at the Horticultural Hall last week to show their autumn leaf tints the Winged Spindle tree was conspicuous. It is remarkable even from its curious "winged" stems alone, and it is equally so on account of its rich and distinct leaf colouring, which may perhaps be best described as pale claret; in fact to say it is the colour of claret and water seems to me to be the best comparison that one can make. The colours of leaves and flowers are often difficult to describe in a manner that will convey a clear idea of them to the reader, and in such cases it is not only permissible but often desirable and helpful to make a comparison with something commonplace, the colour of which is known to everyone. *Euonymus alatus* becomes a striking object in the shrubbery long before many other trees have begun to take on their autumn tints, and for that reason it is worth planting in small groups. When all trees are losing their

foliage in rich and brilliant colouring one is often not more remarkable than another, but while the leaves of most are still green, a tree that then is red or gold becomes doubly valuable. It must be said that the Winged Spindle tree is not very handsome at other seasons of the year, for it makes a rather ungainly specimen, whose branches are none too well clothed with leaves.—Y. Z.

Chrysanthemum Harvest Home. Among the many new varieties that are constantly being introduced the older varieties of merit are in some danger of being lost sight of. There can be no doubt about the value in the outdoor garden of these early-flowering *Chrysanthemums*, for they bloom throughout such a long period and continue until they are spoilt by frost. The variety *Harvest Home* is the one I should like to draw attention to. Its bronze and yellow flowers are produced in great profusion, and, together with the rich green leaves of well-grown plants, a very pleasing colour association results. One can cut bunches of the flowers and hardly detract from the beauty of the bed. There is a splendid lot of it in a bed in Hyde Park; so late in the year its rich, pleasant colouring is much appreciated.—Y. Z.

Foxgloves and Poppies fill a corner in the wild garden with charming effect. The stately

FOXGLOVES AND POPPIES.

spikes of Foxglove bells tower above the dainty many-coloured flowers of the Poppies, and bring brightness and beauty into the duldest corner. The accompanying illustration will show better than words can tell the effect of this flower association.

Linum arboreum.—This yellow Flax is a most valuable plant for the rock garden, for, though a native of Crete, it is practically hardy, living out through the winter unprotected in the neighbourhood of London, and flowering profusely in the spring and summer. It is an old plant, having been introduced into this country about 120 years ago. Its flowers are of a beautiful clear yellow tint, and it commences to bloom in April, continuing to flower through May and June, and often holding a few blossoms well into the autumn. It forms a small bush from 12 inches to 18 inches in height, and often more in the spread of its shoots. In exposed situations it is dwarfer and more straggling in habit than when occupying a sheltered nook, and in light soil in a sunny and naturally protected site in the rock garden it is seen at its best. It retains its branches and leaves

through the winter, and in this differs from *L. flavum*, with which it is often confounded, the latter plant being a true herbaceous perennial, dying down annually, and sending up numerous shoots from the crown in the spring. In leaves and flowers it is hardly distinguishable from *L. arboreum*, the blossoms of each being of the same colour and about an inch in diameter. *L. arboreum* is readily increased by cuttings taken off about midsummer, but rarely produces seed, whereas *L. flavum* seeds freely, self-sown seedlings usually springing up in numbers around the parent plants and flowering in the second year.—S. W. FITZ-HERBERT.

Cassia corymbosa.—This handsome flowering shrub, a native of Buenos Ayres, from which place it was introduced into this country in 1796, is grown under glass over the greater part of England. In the south-west, however, it does splendidly in the open, without the slightest winter protection, and the colour of its flowers out of doors is far brighter than when the plant is grown in a conservatory. There are many noble specimens in South Devon and Cornwall well deserving of mention; one that I saw in flower in August in a Cornish garden covered almost the entire gable end of a dwelling-house. The corymbs of bright golden-yellow blossoms are produced in the month of August, and through the whole of September show no sign of diminution or fading, and often remain in fair numbers through another month, while it is no uncommon thing to see a plant still bearing flowers on the open wall as late as December. Plants grown in the open are deciduous, but rarely lose their leaves entirely until January or later. In the spring, just as the plants are commencing to make growth, such shoots as cannot be laid in are cut back to one or two buds. The plant is easily raised by cuttings taken in the autumn, and inserted in a warm pit or propagating house. They should be grown on gently through the winter and gradually hardened off preparatory to planting out in May.—S. W. FITZHERBERT.

Acacia linifolia.—Of the innumerable forms of Australian *Acacias* nearly all flower during the early months of the year, though one species—*A. platyptera*—has long been noted from the fact that its golden blossoms are borne during the autumn and early winter. A second species, and an uncommon one, also flowers at the same time. This is *A. linifolia*, which, irrespective of its flowers, is a handsome plant. The phyllodes (popularly termed leaves) are long, narrow, and partially drooping, thus imparting grace and elegance to a well-grown plant. The flowers themselves, borne in globular heads as in most of the others, are pale yellow or cream-coloured. It is not suitable for growing in small pots, but a specimen 6 feet to 8 feet high is very beautiful. This species is flowering freely in the Temperate House at Kew, and a specimen close by named *A. nerifolia* appears to be almost, if not quite, the same.—H. P.

Leonotis Leonurus (Lion's Tail).—This plant is rarely seen either in gardens or at exhibitions nowadays, and the group shown by Messrs. James Veitch at the Horticultural Hall on the 18th inst. was very welcome. *Leonotis Leonurus* is a handsome plant with whorls of long tubular orange-scarlet flowers, produced in the axils of the opposite leaves towards the top of the stems. The ground colour of the flowers is creamy white, but this is so densely covered with orange-scarlet hairs as hardly to be seen; the hairs also form a fringe to the margin of the corolla. The plants shown by Messrs. Veitch were about 2 feet high, each having three or four stems crowned with flowers. The plants were raised from cuttings rooted last February, and were grown out of doors during the summer. It may be interesting to mention that this *Leonotis* was one of a number of plants described by Mr. Thompson of Ipswich in his list of new plants for 1884. Mr. Thompson thus writes of it: "Under its older and better name of *Phlomis Leonurus* this handsome Labiate was formerly met with at intervals in English gardens, but amid the crowd of competitors for admission to the flower border it has lately been almost overlooked. It is a dwarf suffrutescent perennial growing 5 feet or 6 feet high in good soil, but flowering in a much

smaller state. The flowers are produced in whorled clusters from the upper axils of the shoots. They are of a fine orange-scarlet colour, resembling in form those of some *Justicias* or the more homely white *Dead Nettle*, the upper lip of the corolla being, however, much longer and remarkable for the fringe of soft hairs. The flowers are produced rather late in summer, and it is, therefore, desirable to plant out as early as possible. It may also be grown in large pots plunged in the border, which will allow of its being removed to the greenhouse for protection when in flower.—Y. Z.

Chrysanthemum Devonshire Cream.—This new early-flowering variety is one of Mr. Godfrey's raising, and is especially pleasing in habit, form of flower, and colour. The latter is deep cream in the centre, changing as the florets unfold to white, with a tinge of pink at the tips of the narrow petals. It is a full-built flower, and most useful for cutting.—E. M.

Polygonum amplexicaule album. This Knotweed is a desirable form of the ordinary red-flowered one, and for naturalising it is a good plant. In height it grows from 3 feet to 4 feet, and gives its pure white flowers abundantly.—E. M.

Pentstemon antirrhinoides.—In a genus which is of considerable extent, and possesses plants with flowers in colours covering a wide range, including blue, scarlet, and white, the above species stands out as the only one with pure yellow flowers. Others have a slight trace of that colour, like *P. breviflorus*, which has yellow flowers striped with pink. *P. antirrhinoides* was first found by Dr. Coulter in Southern California in the year 1824. It flowered at Kew in 1874, and was figured in the *Botanical Magazine*, t. 6, 157. Owing probably to its rather tender constitution, like *P. cordifolius*, it has never become a common plant, for it requires the protection of a cold frame during winter. In its native habitat it forms a shrubby, freely-branching plant, from 1 foot to 5 feet high, with small, oval leaves. The lemon-yellow flowers are unlike the majority of *Pentstemons*, being very short and unusually broad. It is evidently a plant for the warmer parts of this country, and its colour should recommend it to the hybridiser. It does not begin blooming till the beginning of September. Other uncommon species still in flower are *P. murrayanus*, a stately plant from 3 feet to 4 feet high, with glaucous leaves and panicle racemes of showy deep scarlet flowers. This plant is a native of Texas, where it is found on open prairies. *P. puniceus*, which is of somewhat similar habit to the last, but is sometimes said to attain a height of 6 feet in its native habitat in Arizona, is also still producing its deep scarlet flowers. It differs from the preceding species in having a more slender tube and smaller mouth to the flowers.—W. I.

THE FLOWER GARDEN.

PLANTING HERBACEOUS PÆONIES.

FOR planting the herbaceous *Pæony* early autumn is the best time, and the earlier the better. If the work be taken in hand at this season there is every hope that the plants will become re-established in the shortest possible time. This opinion is the outcome of many years' experience. It is the more desirable that the planting should be done at the right moment, because these *Pæonies* do not require to be planted or replanted each year. Far better, indeed, that the plants should be left alone for years, provided that the work of first planting was properly carried out. The chief reason why the *Pæony* should always be planted in early autumn is the production of the main roots at this season, and, as one set of these is produced each year, it is desirable that the planting should precede the period of the issue of these roots. The *Pæony* is always impatient of disturbance and slow to re-establish in any new position, and these characteristics are more manifest when the work is done at what one may call an unseasonable time. If the new main or tap roots have

been produced, and the planting follows, these roots, by their extremely brittle nature, are broken off, and probably the remaining stump injured also. In such a case the freshly-planted subject for its sustenance is mercilessly thrown upon its own resources for the greater part of the ensuing season, and the output of its growth has the effect of considerably reducing its vitality, and, in proportion, in place of a finely-developed crown bud a weakling only is formed at the base. Again in turn this weakling produces its weaker growth, and in this way the mistake and the delay of one year may be responsible directly and indirectly for something like two years' poor growth and development. I have seen it stated, and, unfortunately, in a gardening paper, that the best time for planting the *Pæony* is "in spring, when some 6 inches of new growth has been made."

If the *Pæony*, like the *Phlox*, produced constant supplies of new roots from the crown, the former could be successfully replanted for months in the year. But it is not so, and therefore there is the greater need to emphasise the fact that "now" (early autumn) "is the time to plant *Pæonies*." By planting at the proper time and using plants of moderate size, such as have three or four good crown buds, good blooms may be had the following year, and in the third season the plants should be 3 feet high and capable of carrying an abundance of fine flowers. It is of considerable importance that the *Pæony* should not be planted in large clumps intact. Where it is desired to form a large group the following principle should be adopted: Divide the clump into several pieces of three crowns each, and replant them at the outer edge of a circle of 3 feet diameter, arranging the divisions 18 inches apart. In the third year the group should be 6 feet across and carrying perhaps double the quantity of flowers that a single plant would yield. A few such specimens in a garden or on the lawn would make a good feature, and would do justice to a noble hardy flowering subject. Of considerable importance are soil and treatment, and the former can neither be too deep nor too rich. I have traced the roots of *Pæonies* to 3½ feet without reaching the point, and by reason of this deep rooting the soil of the *Pæony* bed should be trenched fully 3 feet deep, working in almost any quantity of manure. Lay in ample manure at a depth of 2 feet or lower, that the soil may be enriched for the years to come. Nearer the surface shorter manure may be added liberally, and in the case of very heavy soils, road grit, wood ashes, or the ash from rubbish fires may be worked in without stint. Use bone-meal in plenty and lime or old mortar in the more retentive soils; in short, anything that will add to the fertility of the soil, for *Pæonies* like luxurious fare, and amply repay it. Finally, let the surface of the bed be arranged 3 inches below the ordinary level, so that the bed may be flooded a few times in dry weather. Established *Pæonies* in beds or groups benefit by winter dressings of strong liquid manure. Given at this time, when the soil is moist and new roots abound, these are of the greatest possible assistance. E. H. JENKINS.

EARLY-FLOWERING CHRYSANTHEMUMS.

ONE effect of the October show of the National Chrysanthemum Society, recently held at the Crystal Palace, should be to prove to the garden-loving public the usefulness of the early-flowering *Chrysanthemum* for the border. Not the least interesting of the exhibits on this occasion, judging from observations made by visitors to the exhibition, was that of the better sorts that had been grown outdoors. These bunches were cut from plants outdoors that had been grown without disbudding. To some it seemed hardly credible that such an interesting series of flowers were grown in the open. What surprised many was the diverse character of the Japanese flowers and their varied colourings. Dull and dowdy shades were absent, and in their place were charming sprays of flowers of warm and rich colours. It is astonishing how little is known of the early *Chrysanthemums*, and yet they should

be regarded as one of the best—if not the best—flowering subjects at this season. Occasionally one meets with an interesting collection, somewhat isolated, certainly, but all the more appreciated, perhaps, in consequence. Groups of the better sorts planted for effect form a sight worth seeing. By a judicious selection it is possible to create one of the most charming autumn floral pictures that one could well desire. A pleasing sequence of colours planted in association or a contrast effected by an accurate knowledge of the different kinds seldom fails to please, and these points passed through one's mind when looking through the different exhibits at this interesting show.

Conspicuous among the yellow Japanese sorts were *Horace Martin* and *Carrie*, a pair of very useful and effective plants in the border. Of the crimson shades *Goacher's Crimson* was the best. The older *Harvest Home*, however, is a brighter colour, though the flowers lack the quality of the first named. A splendid new early-flowering single of large size, sent out by Mr. H. J. Jones last spring and named *Mrs. Chas. H. Curtis*, is one of the best of the early varieties. The colour is deep rich crimson, and with its yellow disc is most effective. The plant has a good habit and flowers profusely. Another new sort is *R. Pemberton*. This is a pretty amaranth-coloured flower, and is very free. In the border it is very striking, being about 3½ feet in height. *Polly* is an excellent variety, having beautiful flowers of a bronzy yellow colour; this is one of the best things of the past season. *Elenore* (Jones)—there are two sorts bearing this name—is a charming variety. The flowers are of pleasing form, and their colour is deep rose-pink, tinted salmon; height about 4 feet. *Pride of Hayes* is another very good flower of beautiful form, and of a lovely shade of soft rose. Improved *Masse* is one of the largest and best of its kind; far away and above the type in point of quality and colour, too. The colour may be described as clear rose. The plant is rather less than 3 feet high, and the flowers are on stiff, erect footstalks. *Rosie* is also a delightful plant and a really grand flower. The colour may be described as bronzy terra-cotta, and the large, full blooms are each developed on a sturdy, erect flower-stalk; height of plant about 2 feet. *Mrs. W. A. Hobbs*, sent out in 1903, is a gem. The plant is very free, and the flowers are rosy carmine in colour. *Howard H. Crane* was represented in one of the stands, and this is a striking October-flowering variety. The plant is of branching growth, and bears innumerable buds and blossoms, the colour of the latter being a bright chestnut, with a pale bronze reverse. *Mychett White* still holds its own as the best of the white sorts, but its constitution leaves much to be desired. *Nina Blick* is one of the earliest of the newer sorts; the colour is rich golden-bronze, and the growth is excellent. D. B. CRANE.

WILD GARDENING IN SPRING.

(Continued from page 274.)

PLANTING DAFFODILS.

I USUALLY commence planting these about October 1, and get the bulk in during that month, and the rest in during November. I find it better to delay planting some of the bulbs, as I fancy in this way you get a longer succession of bloom. After planting the bulk I go over the whole of the ground, the newly-planted parts as well as the old-established, at intervals of a few days, and drop in a few bulbs here and there, just as the fancy takes me.

In making the holes I cannot too strongly advise that *Barrs'* patent planter be used. It saves a lot of time and trouble, it does its work effectually, and has many other advantages over the pole-bar. I make the holes 5 inches or 6 inches deep, and if the ground is very heavy I drop in a handful or two of lighter soil.

As regards the best varieties for the grass, more especially *Daffodils* and *Tulips*, I would advise tall-growing varieties, free bloomers, and, what is very important, as far as possible varieties of *Daffodils* that rapidly increase.

If we get a growing spring, the shorter kinds are hidden by the grass, as also with the foliage of the

tall-growing varieties. The blooms are thus simply wasted. For Daffodils you cannot beat such splendid kinds as Sir Watkin, 21 inches high; Emperor, 21 inches; Empress, 20 inches; maximus, 18 inches; Barri conspicuus, 20 inches; princeps, 15 inches; Horsfieldii, 14 inches; and the Leedsii, Star, and poeticus type. After testing 50 varieties out of the 500 offered for sale, I think my favourite for grass is Sir Watkin, standing up as it does on its stiff strong stem some 21 inches high, a sure bloomer, with large blooms some 5 inches across, and it also seems to me to stay in flower longer than any other kind. It propagates rapidly, and in a suitable position I have known it to treble itself in two years. The double Phoenix kinds are very pretty, but unfortunately have the disadvantage of hiding their heads in the grass, especially in showery weather. The old Double Orange is more satisfactory. Golden Spur is very good, but does not last.

Our native Daffodil, the common Lent Lily, does better in the grass than anywhere, but unfortunately it is very short, and my grass at Wiggle grows rather rank, so I do not find it satisfactory.

We cannot have too many of the charming sweet-scented Poeticus type, some varieties being three weeks later than others, and, being mostly white, they afford a nice contrast to others, and are particularly conspicuous in the evening light, with the shadows in the grass for a background. They will flourish under trees, and in fact will grow nearly everywhere. I have a weakness for all sweet-scented flowers, even if the bloom is unattractive, but here we have beauty and scent as well. In

TULIPS

I would advise early singles—Darwins and plenty of the May-flowering or cottage. Keizer Kroon is a particularly good and early one for the grass; in fact, nearly all Tulips, practically speaking, look well. But do not have too many yellows, as you have ample yellow in the Daffodils. I would not advise the planting of Parrot Tulips, as they will require some support if they are to make any show. Double Tulips are not so satisfactory, having rather an unnatural effect. In

HYACINTHS

there is not, of course, so much choice. The ordinary mixed bedders will do, but I find it best to have the majority pink, red, white, and light blue. The dark hues do not show up so well. One of the prettiest things I have seen was a mixture of the common Bluebell and what is generally called the white Bluebell (*Scilla campanulata alba*) growing together. The effect was charming. With respect to the

CUTTING OF THE GRASS

I treat it like an ordinary meadow, that is, mowing it about the middle or end of June and then again, roughly, at the end of September. I once left a portion until later on in the summer, by way of experiment, but did not perceive any improvement in the flowers in the spring. The most satisfactory soil for spring wild gardening seems to be a good medium loam, the ground slightly undulating, with just sufficient drainage to take away the surplus water. It is better to have a little shade in places, although it is not essential, but I find the flowers last longer under the trees when we get a warm, sunny spring.

Respecting the use of farmyard manure for bulbs in grass, I recall having tried an experiment by digging out a space and putting in some good rotten stuff, but it was a total failure. My personal opinion is that manure is not required. No doubt some varieties do best on rather heavy soil and others on lighter soil, and, if the soil varies in your garden, it is a good plan I find to take note of the result and next year arrange your planting accordingly.—Paper read by Mr. A. TROWER at a meeting of the Redhill, Reigate, and District Gardeners' Association, September 27.

(To be continued.)

THE ROSE GARDEN.

ROSES FOR SCREENS, HEDGES, AND TRELLISES.

WE have at this planting season received several letters in which a desire is expressed for information about the making of Rose screens, hedges, and trellises. We think the following notes from "Roses for English Gardens" will prove useful to our readers:

Many are the opportunities in the planning of gardens for having a screen or hedge all of Roses. Sometimes it may occur as part of the Rose garden design, but more often in some detached portion of the grounds some kind of light screen is actually wanted. There are often rubbishy or at least unbeautiful spaces on some of the frontiers of the kitchen garden, where a Rose screen or hedge will not only hide the unsightliness, but will provide a thing beautiful in itself, and that yields a large quantity of bloom for cutting. Many are

and pale yellow, with bluish foliage; the middle one of warm colourings of rose, red, scarlet, orange, and full yellows, and the third of purple, pale pink and white flowers, with silvery and other cool foliage.

Chains are generally used to form the garlands from post to post, and they are the best, as they hang in a good natural line. A cheaper and not bad substitute is wire rope. Whether chain or rope is used it is an excellent plan, and much better for the Roses, to wind thick tarred twine, or something stronger than twine—tarred cord as thick as the diameter of a large Sweet Pea seed—round and round the chain or wire, keeping the coils rather close, so that the Rose branches do not actually touch the iron but rest upon the coiled cord.

For the post and low trellis the posts are planted with any of the good Ramblers or Roses of free growth, while the low trellis may have strong growing Hybrid Perpetuals or any of the Teas and Hybrid Teas usually described in Rose lists as "vigorous." In this case two Roses, or three, according to space, preferably of the same kind, would be planted against each panel of the trellis. Another way would be to plant another Rose of

A SCREEN OF ROSES.

the kinds of structure that may be used to support and train the Roses. But with posts of Oak or Larch, and straight long lengths of sawn Larch tips for the top rail, and some wire netting of the coarsest mesh, an effective framework may be easily and cheaply made that in three years will show a perfect covering of blooming Roses. Between this and the elaborately made wooden framings there are many grades and forms of flower wall or trellis that can be arranged according to special use or need. One pretty way is to have a low trellis with posts for pillar Roses at intervals. This can be carried a little further by having chains from post to post. If this should occur on each side of a path, the posts coming opposite each other can be connected by an arched top. This arrangement can also be very prettily adapted to such a Rose trellis at the back of a flower border, either at the two ends of the border or at intervals in its length. It would be an extremely pretty way of having a double flower border in three divisions, with such an open cross screen twice in the length, as well as at the beginning and end. The first division of the border might well be flowers all blue and white

rambling habit against the middle of the trellis and train it down over its next neighbour.

Posts when put into the ground should always have the ends prepared either by gas-tarring or by charring in the fire. This preparation should come up the post quite a foot out of the ground, as damp and rot attack it first at or near the ground line. If a better kind of wooden framework is made, the posts are set on stone or brickwork 9 inches to 1 foot out of the ground.

Roses of the free-growing kinds adapt themselves readily to the form of hedges. One has only to choose a Rose of more or less vigour, according to the height required. The hedge or screen way of growing them has the merit of ease of access for training and pruning as well as that of giving close enjoyment of the living walls of flowers. The tendency of nearly all strong growing Roses is to rush up and leave bare places below. A Rose hedge should, if possible, have a free space on both sides, when this defect can be remedied in two ways; one by training the shoots in an arched form with the tips bent well down, and the other to tip some of the outer strong young shoots that

spring from the base. If in July these are shortened about a third, instead of continuing their growth in length, their energy goes to strengthening the shortened piece that is left. This will then, the following season, be thickly set with flowering laterals that will clothe the lower part of the hedge.

Many of the newer rambling Roses, the old Ayrshires and the stronger of the Teas, are admirable for this way of growth, while there are Roses to suit every height. The height of the Rose hedge, as in all other matters of garden design, must be determined in relation to the proportion of the space it is to fill and the size and distribution of whatever may be within view. Nothing is gained by carrying it up to a great height; 8 feet or 9 feet is in most cases the limit of desirable height, while anything from 4 feet to 7 feet will be likely to suit the wants of most modest gardens. A charming hedge 4 feet high can be made with the old favourite Mme. Plantier. It is all the prettier if there is a short standard of the same at regular intervals. Another pretty hedge of the same class can be made with this good Rose in combination with one of pink colouring, such as the old Hybrid Perpetual Anna Alexieff. We know a pretty Rose hedge where the two are mixed; not planted alternately, but two or three of one kind and then one of the other, and so on in irregular sequence. Or it would be charming to have short standards of Anna Alexieff rising as just described from the low hedge of the white Mme. Plantier.

No one would regret some planting of these two excellent old garden Roses. This one example is given as a type of this kind of planting. Any one who tried it and had enough garden sensibility to feel its charm, and enough garden fervour to wish to practise it in varied forms, would soon invent other combinations.

It would be easy to name many such desirable mixtures, but it is more helpful to show one simple thing that is easily understood, and that awakens interest and enthusiasm, and to leave those wholesome motive powers to do their own work, than it is to prompt the learner at every step, fussing like an anxious nurse, and doing for him, what, if his enthusiasm is true and deep and not mere idle froth, will give him more pleasure in the doing, and more profit in the learning, than if it were all done for him. For the very essence of good gardening is the taking of thought and trouble. No one can do good decorative work who does it merely from a written recipe.

COLOUR IN THE MIXED BORDER.—IV.

BEFORE proceeding to describe the planting of the next section, I think a few words of advice would be welcome. I am anxious to make every little detail quite clear, as without this these articles may end by misleading the very people they are intended to assist. In dealing with the material to be used in the section it must be borne in mind that many of these plants require consideration and slightly different treatment, and the most important point of all is the way the hardy perennials are planted in the first instance. The method which seems to be universal is to grub a hole with the hands, throw the plant in, and tread it down with the foot. There is no regard shown for the exquisite delicacy of the root, whose food-finding fibres are so fine that that they can only be seen through a microscope. These roots should be handled carefully, spread out with the fingers, the hole filled in with the soil and a little sand, or some fertiliser added, according to the wants of the plant, and then with the hands it should be pressed firmly into the earth so that the frost cannot force it out of its position.

Many Wallflowers are lost every winter owing to careless planting. It takes a great

deal of time, I allow, but no good work can be done without taking time, and the difference it makes in the end is incalculable; in fact, I consider the whole future success of the border depends on it. There is another thing I should like to impress upon you: Gardening is a "waiting game." Rome was not built in a day, and the same proverb applies to the mixed border. You cannot have a good show the first year. The Delphiniums, for instance, will probably be quite small plants, for very few houses send out large stuff, which is really best in the long run. As you cannot plant everything in the autumn, you must leave a definite space for those more delicate subjects that have to be put in their permanent quarters in the spring, and also for the annuals that have to be sown and pricked out. It is impossible for me, with the best intentions in the world, to particularise all these things, but your gardener, if he deserves the name at all, will be able to advise you, or you yourself are probably quite as well up in these details as I am. Besides, there is a great difference of opinion on the *when* of planting, and it is only by personal experience, often dearly bought, we gain a position from which we can lay down the law on the "ins" and "outs" of gardening.

All the Primrose tribe like a due degree of moisture, and seem to prefer a west border. Pansies thrive better if they are given a portion of rich moist soil, and they like good food and require it, for they blossom profusely for four or five months. All delicate bulbs are better planted in the spring, and when once established, unless they have to be lifted, ought to be protected every autumn by putting wood ashes over them, not cinders; this is very important. When you plant your Phloxes give them extra good soil, because they suffer from drought more than any other plant, and from their usual position at the back of the border do not always get the full benefit of passing showers. I have found it an excellent plan to add a little prepared compost to the soil when planting any particularly fanciful subject—with the Lily tribe especially—but of this more anon.

Yellow being the next colour in our scheme, we will now deal with it. Happily, we have a large choice, for it is a tint that in the flower world predominates greatly. We have also plenty of tall plants for the background of our section, so many, in fact, that to decide on their several merits is somewhat difficult. In profusion are the perennial Sunflowers, *Helianthus*, *Helianthus pumilum*, and *Helianthus*, of which Miss Mellish is an established success. These are supplemented by the handsome annual Sunflowers planted in May, and we can have the Golden Rods and the beautiful sulphur-coloured Hollyhocks, and to flower before these the yellow Foxgloves. *Oenothera grandiflora* will do in the background, but, I warn you, it is distractingly untidy. For early spring flowering you might plant, far back, Broom and Berberis, always supposing your ground lends itself to such treatment. The perennial Sunflowers, the Hollyhocks, and *Solidagos* at that season will be hardly above the ground. Next comes the Lupin, a beautiful and useful thing, and in the early summer the *Aquilegia chrysantha*, a yellow hybrid and quite one of the prettiest, will flower, followed by *Antirrhinum Cloth of Gold*, which will bloom persistently until autumn if you cut off the seed-pods. Day Lilies and yellow Iris, English and Spanish, will come in well, and plenty of Wallflowers for April and May, double and single. The old double yellow is splendid, but too little seen now and difficult to get, for it must be grown from cuttings to have it true.

You can plant Tulips now, Canary Bird among the other yellow varieties, and plenty of Daffodils—you may keep to the yellow self if you like, but I do not think it matters—and there is the *Polyanthus Narcissus Soleil d'Or*. Put in some sand with all your bulbs—it will keep them healthfully dry all the winter; good clumps of *Trollius*, too, but these will not do much the first year. For Carnations, *Cecilia*, which Mr. Martin Smith says is the best yellow he ever raised, and Miss Audrey Campbell; a pinch of soot will warn off the wireworm; and if you have a greenhouse you can grow some French Marguerites to put out in the summer. For carpeting try *Mesembryanthemum cordifolium* and, if your climate is temperate, *Oxalis luteola*. Towards the front plant yellow *Alysum*—*saxatile compactum* is its botanical name—Iceland Poppies, and Primroses, double and single; the double variety likes plenty of moisture, and is very unhappy if thwarted, so pamper it with a little rotten leaf-mould, and do the same, adding some silver sand, for the charming yellow *Auricula Daisy Miller*; it is well worth the trouble. Have plenty of yellow Violas and Pansies, and there are beautiful hybrid Cowslips, but I do not recommend the giant variety, which is coarse and presuming.

The first and sweetest of all yellow flowers is the little harbinger of spring, the Winter Aconite (*Eranthis hyemalis*), but I should plant it in the grass; it is infinitely more beautiful there than in its loneliness on an earthy border. Its small yellow face and green collar will appear on a fine February day in the springing herbage, when the blackbirds' first song is heard from the Apple trees' bare boughs. In the orchard, too, I should plant all the Crocuses, and as the yellow one comes first, put it in a good twenty days after the blue and white, and all three colours will flower together. For yellow annuals, with which addition your fourth section should be well filled, I have written down the *Tropæolum*, *Bartonia aurea*, *Chrysanthemum coronarium*, single and double, and *Coreopsis coronata*. By the by, do not forget to plant *Coreopsis grandiflora* as a biennial, *Linaria Golden Gem*, *Tagetes signata pumila*, and, if you do not object to their pushing ways and pungent scent, there are the French Marigolds. Most charming of all the annuals are the yellow *Nemesia strumosa* and Sweet Sultans. There is a nice bushy dwarf Lupin, too, and now I think I have exhausted my list of yellow flowers of any worth. Next we must find our purple contingent, not by any means as easy as the last, though it is astonishing how many purple flowers there are. Quite at the back you may plant *Honesty*; it is a true purple and a very early flowerer. When you have done with it you can pull it up at once, and plant out Sweet Peas, sown in January and grown in heat. Dorothy Tennant is the nearest approach to a good purple. Put plenty of stable manure into the ground, and turn them carefully out of the pot, train them on Pea sticks trimmed neatly and painted green, and they will flower all the summer. The Sweet Rocket, double and single, will bloom soon after the *Honesty*, and for the summer you can have purple Loosetrife—the "long purples" of Ophelia's fatal gatherings. From which legend you will see that it is a lover of moisture, and beware of its wandering tendency. Foxgloves will flower next, and Hollyhocks will complete the chain until you get to the season of the Phloxes and Michaelmas Daisies, among which plants there are several purple varieties. Of smaller flowers there are plenty. There is quite a good purple Wallflower, single and double; Iris, English and

Spanish; *Campanula glomerata* and Canterbury Bells, double and single; Brompton Stocks, and Sutton's Perfection, a splendid colour. There is, I believe, a purple *Pentstemon* called *Melodrama*, which is good, and so is *Verbena venosa*, and I have heard lately of a new hybrid *Lobelia syphilitica*, grown by Latham of Southampton; it belongs to a series of hardy *Lobelias* that ought to be invaluable for autumn bedding. Then, further forward, we have a host of pretty things—*Anemones*, *Auriculas*, *Primroses*, double and single, *Pansies*, and *Violas*. Then, for filling in, *Aubrietia Campbelli* and a *Centaurea* with silver foliage. For annuals we shall not do badly. There are Sutton's royal purple *Aster*, *Linaria*, *Sweet Sultans* again, *Whitlavia grandiflora*, *Venus's Looking-glass*, *Verbascum*, and *Candytuft*.

I have made a point of adhering as much as possible to a true purple, because its conjunction with a primary colour demands it, and you thereby save the paler lilac shades for your eighth section to follow orange. In full sunlight the purple shades are extremely harmonious, blended as they are with the different shades of green, but you would do well again to employ variegated Grasses and foliage plants to give a lighter effect on sombre days. The variegated Maize and Ribbon Grass might again be used with many others of like pictorial beauty and value. I find the sweet-scented *Geraniums* are useful and very decorative mixed with border plants, and several of these have a proportion of white in their foliage. AUGUSTA DE LACY LACY.

NOTES ON HARDY PLANTS.

ANEMONE JAPONICA WHIRLWIND.

AMONG the many varieties of the Japanese *Anemone Whirlwind* is well worth planting. Its pure white semi-double flowers make a good display, as may be seen by the illustration of a bed in the Royal Gardens, Kew. The flowers are not so double as to lose their beauty, as many double flowers do; there is simply an additional row of petals, and the flower apparently retains its singleness. This variety is very free flowering, and the blooms last in full beauty a long time.

CROCUS PULCHELLUS

A RATHER lengthy acquaintance with the exquisite little *Crocus pulchellus* enables one to say with considerable confidence that it is one of the best of the autumnal flowering sorts. Were they more frequently seen by the general number of flower-lovers they would increase in favour with still greater rapidity. It is true that they suffer in stormy weather, such as we frequently experience in an ordinary autumn, but there are few flowers which do not do this, and the beauty of the *Crocus* is so great that even a few days of its blooms in perfection will more than reward us for some disappointments. As a grower of a representative collection of both spring and autumn blooming species I can say that among them all none is more welcome than the little *C. pulchellus*, a dainty *Crocus* of an exquisite pearl-blue, or, as some call it, a blue-lilac.

It is of charming form, with deeper lines on the inside of the little cups. It is no slight merit of *Crocus pulchellus* that it increases freely by means of seeds, much more so, indeed, than any autumnal species with which I am acquainted. In consequence one soon becomes the happy possessor of a good stock of this *Crocus*, while if it is allowed to seed naturally quite a colony of young plants will soon spring up around the parent corms. When naturalised in the grass these soon make a pretty feature, being much more attractive than when in a formal group. As a *Crocus* for planting in grass this species is valuable. Its flowers are produced before the leaves, so that it requires some carpeting to show it to advantage. If it is grown in the border or on the rockery it should be carpeted with a dwarf plant, choosing for this purpose one which is not a favourite of the slugs. These are particularly fond of *Crocus pulchellus*, and seem to come from all parts of the garden to feast on it and *C. zonatus*, another autumn species indispensable in the garden in autumn. *C. pulchellus* is perfectly hardy, and comes from heathy places and woods on both sides of the Bosphorus, by the shores of the Black Sea and elsewhere in the East. No one who cares for the *Crocus* should be without this little flower. Carsethorn, by Dumfries, N.B. S. ARNOTT.

KNIPHOFIA NELSONI.

It is doubtful if any of the Torch Lilies are so generally admired as Nelson's species, thriving colonies of which are a source of real pleasure in late autumn. The plant has been known to cultivation for a long time, yet is still far from common, and thriving colonies with fifty or more spikes from each clump are still rare enough to occasion surprise that it is so little grown. It is a slender-growing species, whose *Eulalia*-like leaves rarely exceed 2 feet in length, and the dainty spikes of coral, tubular flowers, more refined even than the *Lachenalias*, are among the very best things to be found in the autumn garden. The plant is hardy enough anywhere in Britain, but it cannot withstand a wet winter in heavy soils. Planted high up on a rockery ledge where its roots can find what moisture they require in summer it will thrive apace, and one should always plant it whilst in flower or in late spring as it is starting into fresh growth. It will thrive anywhere in dry and warm gardens. G. B. M.

EOMECON CHIONANTHA.

THOSE who are in search of a free-flowering plant that will thrive with *Hepaticas* and *Cyclamen* in

cool, damp, and shady places cannot do much better than plant *Eomecon*, an extremely pretty plant from China, known as the Chinese or *Cyclamen Poppy*. It thrives in a deep soil of vegetable formation, producing glaucous, heart-shaped leaves that are miniatures of *Coltsfoot* in shape and manner of growth. The flowers are borne in graceful spikes 18 inches high, freely branching, and very prolific in their yield of flowers. These closely resemble *Argemone grandiflora* (the Prickly Poppy), being white, satiny in texture, with a large cluster of beautiful yellow anthers in the centre of each flower. It is an effective plant for the bog, marsh, and damp border, very beautiful in September when the flowers are in greatest yield, and increasing freely where given plenty of room. Its pink, fleshy rhizomes delight to ramble over half-buried stones, and the flowering growths form a charming picture in a setting of Ferns. Every piece of the rhizome is capable of forming a plant if carefully cultivated, but *Eomecon* is never likely to become so troublesome as *Mimulus* and kindred moisture-loving subjects. G. B. M.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOVELTIES AT THE HORTICULTURAL HALL.

THE meeting of the Royal Horticultural Society, held at the new hall on Tuesday, the 18th inst., was remarkable for the fine display of *Chrysanthemums* set up by most of the trade growers. There were large exhibition Japanese blooms in great variety, and many of them were displayed in large vases. In this way the uses to which the large blooms can be put were well illustrated. Among the Japanese blooms the following were specially noteworthy: *Renée*, lilac-mauve; *Henry Perkins*, an immense bloom, having very long and broad twisting and curling florets; colour, chestnut-crimson on a rich yellow ground; *Lady Curzon*, a pretty pure yellow bloom, with straw yellow reverse to florets; *Mrs. Bischoffsheim*, tinted crimson-scarlet on rich yellow ground; *Mrs. C. Beckett*, a lovely white bloom with greenish centre. Mr. George Mileham sent a very dainty Japanese seedling named *Miss Dorothy Olliver*, white, flushed and lightly tinted with rosy violet. Although not absolutely new, the blooms of *Lady Hopetoun* are sufficiently so to be mentioned

ANEMONE JAPONICA WHIRLWIND AT KEW.

here. They are very large, having broad reflexing and drooping heliotrope pink florets. Under the same heading come the blooms of Lady Mary Conyers. The colour of this useful Japanese flower is rose-pink, with a silvery reverse. A striking exhibition Japanese bloom is E. J. Brooks. The colour inside the florets reminds one somewhat of Pride of Madford, and the outer colouring is a silvery bronze. An enormous Japanese flower is Miss Edith Fuller. This is distributed as a sport from the popular General Hutton. The colour may be described as buff-yellow tinted and suffused reddish bronze. The rich yellow Beauty of Leigh asserted its value as a useful flower to exhibitors. A mass of the rich crimson blooms of George Penford, with bright golden reverse to the florets, was most attractive, and this contrasted with the lovely creamy white blooms of the new Miss Mona Davis. Henry II. is a novelty that may improve on acquaintance later. It is Japanese, reddish crimson inside, with a bronze reverse. Edith Smith has been in commerce two or three years, and at length has been recognised by the floral committee of the Royal Horticultural Society with an award of merit. The colour may be described as creamy white, the lower petals being faintly tinted pale rose.

Maud du Cros, so highly thought of as a novelty last season, promises well. In one exhibit there were several handsome blooms of this soft pale yellow Japanese kind. It should stand exhibitors in good stead later. Phillipe du Cros, by the same raiser as the last mentioned, is a useful variety. The florets in this instance are narrow, and the colour is bright red, tinted gold. A large drooping Japanese bloom is Mrs. M. J. d'Arcy, the colour being pale yellow. Specially effective were the intense crimson blooms of Mrs. D. Willis James. Of the older kinds seen in fine form and condition were Mrs. George Mileham, Miss Mildred Ware, and Miss Elsie Fulton. D. B. CRANE.

TREES & SHRUBS.

LIGUSTRUM QUIHOU.

MORE frequently ought this little-known Privet to be grown in gardens, as it flowers very late in the year, and is one of the most ornamental species when in bloom. It was introduced from China nearly forty years ago, but never appears to have been planted to any great extent. It forms a dense bush 6 feet to 8 feet high, made up of numerous wiry branchlets, which, when young, have a purplish tinge. The leaves are very ordinary looking, being small and ovate. The flowers are white, and are borne in long, loose, terminal panicles during September and October, a time when flowering shrubs are few in number. For grouping in shrubberies it is an excellent plant, but it is doubtful whether it would be worth growing as a hedge plant, for when young it grows very slowly, and cuttings cannot be obtained in such quantity as they can from *L. ovalifolium*. W. D.

FORSYTHIAS.

THE old Forsythia viridis is now in its second period of beauty, the leaves having taken on a rich

tint, which they will keep until they fall. Coloured foliage is so much in demand for autumn decoration that this should be made note of. Those who possess large gardens cannot afford to ignore Forsythias. They yield a rich harvest of bloom just when we want all the colour we can get in the outdoor garden. They are so easily grown that one might say they need no culture. It is true that as regards soil they appear to be equally at home in heavy loam and in soils verging on sand; in fact, they flourish in ground which is incapable of supporting most flowering shrubs; the situation is, however, important, for the Forsythias are sun-lovers, and if deprived of their rightful amount of sun and air their decorative worth is not shown. *F. suspensa* is admirable on fences, walls, or in any position where it can extend and grow away wildly. In such circumstances it has a delightful appearance, and when placed so that the wood can ripen

In the coldest parts of the country it would be incorrect to call any Fuchsia really hardy, while even about London they are usually killed to the ground line in winter. In the south-west counties Fuchsias are seen at their best, for they there make magnificent bushes 8 feet or 10 feet high and as much through, which in their season are smothered with flowers. These counties are not, however, the only places where Fuchsias thrive in the open, for in many places on the West Coast they do remarkably well. In North Wales fine plants may be found, and they may also be seen in the Isle of Man, about Morecambe, some parts of the west of Scotland, and other places. In many of these parts, however, they are only found as large bushes within a mile or two of the sea, further inland they behave as they do about London, unless they are in an exceptionally favoured district. Devonshire, Cornwall, South Wales, and parts of Ireland are the places where Fuchsias do best, and there they are largely grown, though strange to say one or two varieties only are to be found in quantity. About Penzance some fine bushes of the newer and double flowered varieties are to be seen in cottage gardens, and they have been out a number of years, so there seems to be no reason why the majority of Fuchsias should not thrive outside there. It is, however, with the few that are generally considered hardy that we have to deal.

F. arborescens is a strong growing species from Mexico, having large oval leaves and rather scarce red and purple flowers, which are borne from near the ends of the branches.

F. exoniensis is a very free hybrid, with red and purple flowers, and makes a very nice bed when cut back annually.

F. macrostemma.—This is the most important hardy species. It is a native of Chili, and is said to have been introduced about 1823. When at its best it is seen as a shapely bush 8 feet to 12 feet high, with ovate leaves and elegant, pendulous flowers, the calyx of which is bright red, the corolla purple. The flowering period extends over a considerable time, beginning in June and ceasing with the appearance of frost in winter. Of this there are numerous varieties, which differ in habit and size of flowers, the colour of all being the same as that of the type. Some of the best varieties are conica, corallina, discolor, globosa, and gracilis.

F. Riccartoni is the most largely grown of all the hardy Fuchsias, and is one of the best. It makes a shapely bush 10 feet high, of sturdy but graceful habit, and bears showy red and purple blossoms in great profusion. A very fine bush of this is growing on the lawn at Ludgoan Rectory, near Penzance. A double flowered variety quite as hardy as those mentioned above, called *Enfant Prodigue*, is in culti-

vation and is well worth growing. Given good soil all these Fuchsias thrive well, and even if killed to the ground in winter they come up again strong in spring, and make very effective beds during summer and autumn. There are few more beautiful flowering shrubs than Fuchsia Riccartoni. The slender shoots are crimson with the wealth of drooping flowers, and the whole aspect of the bush is so graceful that one cannot well have too much of it. It is frequently seen in cottage gardens, and is a great success by the sea coast, where it attains a considerable height; but it is at home everywhere, growing and flowering freely even in a suburban garden, though not in the same way as in the country. W. DALLIMORE.

A VALUABLE LATE-FLOWERING PRIVET. *LIGUSTRUM QUIHOU* AT KEW IN OCTOBER.

properly it is in its season one mass of golden yellow. *F. intermedia* is one of the most handsome flowering shrubs we have, and is worthy of a place in the garden. It demands considerable space for development and deserves good treatment. Many fail to realise that flowering shrubs need light, air, and sunshine, and that without these essentials they cannot show their true value.

Byfleet.

J. CORNHILL.

HARDY FUCHSIAS.

THE majority of Fuchsias which have claims to hardiness can be traced to one or two species. Most of them are varieties of *F. macrostemma*, or hybrids with that species as one of the parents.

NEW AND RARE PLANTS.

CYPRIPEDIUM F. K. SANDER.

IN the accompanying illustration this beautiful new hybrid *Cypripedium* is well shown. It was obtained by intercrossing *C. Annie Measures* (itself the product of *C. bellatulum* and *C. dayanum*) and *C. bellatulum*. Messrs. Sander and Sons, St. Albans, the raisers, exhibited it before the Royal Horticultural Society on the 18th inst., when the Orchid committee gave it a first-class certificate. The broad dorsal sepal and the large petals have a creamy white ground colour, which is heavily spotted with crimson. The spots are so numerous in places as to form irregular lines. The lip is long and pointed, white, with numerous small dots.

ROUND ABOUT A GARDEN.

THE MULTITUDE OF WORMS.

WHEN the Dahlias have been blackened by frost, the garden suggests a funeral of the dead summer; and there almost always follows a revulsion of the weather to damp, warm, clammy days, when all the herbage seems bathed in tears for the sad event. And, after that, it appears only natural that the garden should be overrun with worms, in the grim sequence of Nature. Then sometimes, if there has been heavy rain during the night, one wonders where all the dead worms on the hard paths can have come from; but no room is left for wonder if, with a lantern, you look at the sodden surface of a lawn on any of the muggy evenings which usually follow the frost that cuts down the Dahlias. Often on the whole surface of a lawn there will not be any spot where you could plant your foot without crushing several worms of various sizes, all lying with half their length exposed upon the short-cut grass. You realise, in fact, that the entire surface of the soil must resemble a rich Plum pudding with worms for the Plums, and you cease to be surprised that the thrushes can, in open weather, find breakfast, lunch, and dinner on the same corner of the same lawn every day.

ARE WORMS INJURIOUS?

But the very fact throws doubt upon the supposed "utility" of thrushes in this respect. For reasons which cannot be very clear in anybody's mind, we have all got into a way of regarding it as a certificate of good conduct for any bird when we can say that it "eats worms." For this the rook is often extolled as the

farmer's friend; and on this basis the value of the starling has been worked out in large sums of money to the agriculturist whose land it frequents. Yet, if the worm is so harmful that we may take the measure of its destruction as the standard of the utility of birds, how comes it that the lawn looks always so velvety green and healthy, despite the presence of a large lobworm under every few square inches of the soil? In a wide, evolutionary sense, Gilbert White suggested, and Darwin laboriously demonstrated that, but for earthworms, we should have none of our smiling landscapes of to-day. Not only would the surface of the inhabited earth be yards deep in accumulated rubbish, but we should have to excavate mines through

what mischief justifies us in praising every bird which eats worms. To plants that are weakly the worm may be a terror. A great lobworm will catch hold of the limp leaf of a seedling which flags after you have planted it out, and will drag the little plant by force into its burrow, so that next morning you may find a treasured *protégé* standing upon its head in a worm-hole, with its little roots in the air. Yet, taking the general effect of the work of worms over any half acre of ground, it is probably undeniable that they do good by eliminating the weaklings and the injured plants, and creating space for the vigorous to flourish in.

MORE USEFUL THAN HARMFUL.

Of course, in the confined space of a flower-pot an active, hungry worm cannot help doing harm to the roots of a plant, but out in the open among healthy and vigorous plants it probably does more good than harm. For we must remember that the worm, unlike the snail or slug, has no teeth of any kind. It obtains all its food by suction, and before it eats dead leaves it has smeared them with a fluid which hastens their decay. Then it is able to suck off fragments of the softened tissue. But all this cannot be done in a minute, so the worm has to drag the leaves which he intends to eat into his burrow—very cunningly catching hold of the small end of each leaf for the purpose—to deal with them at leisure. Living vegetable tissues would not easily be softened enough for the worm to dispose of them by suction, and it is therefore very doubtful whether the birds which eat worms do any good at all for the plants and us.

THE WORM'S WORST ENEMIES.

And it is pleasant to be able to say a good word for the worm, because, although we still have the savage instinct of repulsion from anything snakelike in shape, and our civilised instinct for clean hands makes the sliminess of the worm an added offence, yet there is something pathetic in the lot of a creature which is blind, deaf, and unarmed amid a host of enemies. For neither the birds nor the voracious mole or mouse, or shrew or hedgehog, frog or toad are the worm's worst

foes. It is often eaten horribly alive by slugs, both large and small; and there is a peculiarly active and common beetle whose grub spends its life playing ferret to the worm's rabbit, inasmuch that the gulls and plovers which haunt our fields in winter are said by some observers to obtain most of their worms by watching for those that are "bolted" by this beetle grub. At any rate, gulls have been shot with the savage grubs still clinging to the worms in their crops. Centipedes, too, and the "Devil's Coach-horse"—that fierce-looking black insect which cocks its tail and opens wide its jaws if you threaten to touch it—have hitherto been

CYPRIPEDIUM F. K. SANDER.

(Natural size.)

(Raised, and exhibited on the 18th inst., by Messrs.

Sander and Sons, St. Albans. It was given a first-

class certificate by the Royal Horticultural Society.)

A TERROR TO WEAK SEEDLINGS.

Of course, this is only a figure of speech, for Nature loses no opportunities. If worms did not eat the rubbish and renew the surface soil by turning it up in the search for food, some other creatures would have been evolved to batten upon the annual decomposition of the corpse of summer. It so happens, however, that this very useful function has devolved upon the worms; and in comparison with the good which they thus do it is not easy to specify

held to justify their horrid existence solely by their energy in killing worms. Inasmuch, moreover, as most of these creatures are considerably smaller in bulk than the worms upon which they prey, the slaughter is a prolonged and cruel business.

On the whole, therefore, the balance of sentiment, as of reason, seems to be on the side of the worms; yet it is very unlikely that any such considerations will prevent that additional stroke of the spade with which the gardener bisects such worms as are exposed on each upturned clod. Yet, even from the gardener's point of view, the blow might well be spared, seeing that nature has given to the helpless worm such recuperative powers that when cut in two each half is able to become a separate and complete worm. When, therefore, a gardener is "doing up" the garden in autumn, and divides the worms as well as the clumps of perennials amid which he finds them, he is often unwittingly multiplying both. E. K. R.

A GENERAL CALENDAR.

RENOVATING OLD LAWNS.

IT is of the utmost importance to remember that grasses and Clovers require for their well-doing a well-nourishing soil. It matters not how good the soil may be in the first instance, if we cut and carry we labour constantly to impoverish the top soil. In every barrowful of grass removed there will be a certain quantity of phosphates and other constituents of vegetation abstracted from the soil. To be always taking off and putting nothing on must result in the starvation of the grass; and we shall find that as the grasses and Clovers disappear through the exhaustion of the soil Daisies, Plantains, Knotgrass, and other weeds will take their place.

The remedy.—The simple remedy for this state of things is manuring, and the best way of manuring is to scatter over the turf a succession of thin dressings of guano and fine mould mixed together. This should be done now and again in the spring, at times when there is not much traffic on the grass, and there is likelihood of rain to follow. If appearances are of no consequence, in the autumn a good coat of half-rotted manure may be spread over the turf, but this proceeding cannot be recommended for general adoption.

Pot Roses.—Now that the cold and wet weather combined with rough winds is upon us it seems a pity to lose any of the numerous buds showing on the latest batch of pot Roses, more especially as we are getting short of this and other flowers. If we allow these plants to remain in the open with the object of ripening them more thoroughly, I do not think this would be accomplished in a more satisfactory manner than by giving protection during the roughest weather. Plants that are not needed for forcing until the spring should be placed in a deep pit, and the light only put over them upon clear nights when frost threatens and during heavy wind or rain.

Cleaning hot-water apparatus.—For the next few months the apparatus for heating fruit houses will be at rest, and an opportunity will thus be afforded for overhauling it. With the many duties connected with horticulture, this matter is apt to be overlooked, more often from want of time than inclination. It is time well spent, however, and in addition to examining the boilers themselves, the flues should have attention. These should be well cleaned and all defects made good. When the boilers and pipes are sound, draw off the water and wash out afterwards to remove all sediment. If this is done once a year it prevents a great deal of corrosion in both pipes and boilers.

Lifting unfruitful trees.—When trees make too much growth and bear very seldom or not at all, lifting is the best method of restoring them to a fruitful condition. This invariably brings about

the desired result, and is preferable to root pruning. The chief aim in lifting is to check an exuberant and unfruitful growth, to direct the energies of the trees into another channel as it were, and cause fruit-buds to form instead of a preponderance of wood-buds. Once the trees are brought into subjection and they start bearing, they seldom give further trouble. If lifting were only more practised so many complaints about unfruitful but otherwise healthy trees would not be heard of.

Cool orchard houses.—Most of the fruit in these structures will now have been gathered, and where the trees are grown in pots they should be lifted and plunged outside, the ground between them being mulched with litter. This will act as a preventive against split pots later on through the frosts. Where the trees are planted out the borders should receive attention, giving them a soaking of water at least once a week, so that every particle of soil may be thoroughly moistened. It is a great mistake to allow the roots to get dry and then to simply give the borders a soaking just as the trees are starting into growth. Much of the mischief in the way of the buds falling before they have expanded is owing to this treatment.

Winter Spinach.—This important vegetable I am afraid will not be over plentiful this year, as rain in many districts was too late to promote a strong growth. The greatest scarcity will be on shallow, hot soils. Those who are fortunate enough to possess a good healthy bed will find almost any amount of trouble repaid. A good sprinkling of soot should now be given between the rows, and the Dutch hoe used freely afterwards. Moderation in picking must be observed, as if too closely pinched the plants get a check, and growth proceeds but slowly during the winter. Norwich. T. B. FIELD.

BOOKS.

*The Book of the Iris.**—This little volume, which constitutes No. XXI. of a series of handbooks of practical gardening, is a useful addition to the literature dealing with this popular family of garden plants. Its moderate price should place it within reach of all, and it will, no doubt, stimulate the interest already bestowed on this valuable and ornamental genus. Most fittingly dedicated to Sir Michael Foster, whose work amongst the Irises is so well known, it is divided into two parts. The first part consists of twelve chapters, of which the first is devoted to the structure and natural history of the flower. In Chapter II. is given a selection of the most ornamental species for the formation of an Iris garden, with an indication of the needs of various species. The subjects of labels is also touched on in this chapter, accompanied by illustrations of those recommended. The culture of the *Oncocyclus* section is dealt with in Chapter III. by the late Rev. Henry Ewhank, M.A., who tried very hard to successfully grow this class of plants, with various results. In it he discusses the difficulties and disappointments attending their culture, with the means that he employed to overcome them. This is a most interesting chapter, containing much valuable information. Chapter IV. deals with the cultivation of the various groups, with hints from Mr. Carl Purdy on growing Californian Irises; from Messrs. Boehmer and Co. of Yokohama on *Iris lavigata*; and from Sir Michael Foster and several other well-known specialists on growing the plants of the *Oncocyclus* section. Chapter V. deals with the various hybrids, of which there are many, and which promise to become more numerous. The diseases to which Irises are subject are considered in Chapter VI., and remedies prescribed for dealing with them. Part II. is devoted to the classification of the numerous species belonging to the genus. A key is given, in which they are divided into twelve principal sections, grouped according to certain characteristics. Then follows a list of 140 species, with descriptions and references to figures,

* "The Book of the Iris." By R. I. Lynch. Published by John Lane, Bodley Head, Vigo Street, London. Price 3s. 6d.

accompanied by notes on the special culture of individual species. Numerous full-page illustrations add greatly to the value of the book, which consists of 200 pages, and will be found very useful for reference by those who want to cultivate these beautiful flowers.—W. I.

THE KITCHEN GARDEN.

VEGETABLES AT ALDENHAM.

WHEREVER vegetables are staged for competition or exhibition only, the name of Beckett is invariably associated. At the leading shows in various counties the Aldenham vegetables have been so successful and so much admired that visitors marvel at the results and wonder how they are produced. Having quite recently spent some time in inspecting the various items of interest, it occurred to me that those readers of *THE GARDEN* who have not the opportunity of seeing for themselves how these wonderful vegetables are produced might be interested to hear about them.

Nothing is left to chance; whatever is attempted is done well. Mr. Beckett believes in a thorough preparation of the soil, and deep trenching is practised. If the soil will admit, 3 feet deep is none too much. Abundance of manure, too, it is needless to say, is used, and so is water when required. Mr. Beckett believes in testing sorts that appear to possess merit. At the expense, perhaps, of being a little tedious, I purpose taking each vegetable separately, making a few remarks on each, as by this plan a few hints may be conveyed to those who are anxious to learn.

ONIONS.—In a collection of vegetables Onions are an important unit. The practice which is now universally adopted by up-to-date exhibitors is that of growing Onions from January-sown seed as compared with the autumn sowing of Tripoli varieties for the shows in August and onwards. An Onion that does not weigh 2lb. in August nowadays is not thought much of; it is not uncommon to see them weighing 3lb. Some 1,200 bulbs were grown at Aldenham this year. As to variety, Ailsa Craig, Cranston's Excelsior, Carter's Record, and Ne Plus Ultra are grown. The same plot of ground has been chosen for this crop for the last ten years, which entirely refutes the idea that a yearly change is necessary. A thorough preparation, such as deep trenching and manuring, is annually given. The seed is sown in boxes in gentle heat early in January; the plants are pricked off into other boxes, kept growing steadily and sturdily until the middle of April, when they are planted out in rows 15 inches apart and 14 inches from each other. The surface of the soil is kept stirred and watered every ten days during dry weather. An occasional sprinkling with Clay's Fertilizer is given; mulching the surface is not practised on the heavy soil.

PEAS are important in a keen competition. The new Pea, Edwin Beckett, has done much to raise the quality of this vegetable, and is one of Mr. Beckett's own raising. The pods are large, quite shapely, and well filled with large Peas of excellent flavour. Good as this Pea is Mr. Beckett has succeeded in raising another superior to it. In the new sort it is not an uncommon occurrence to find eleven and twelve Peas in a pod. It grows 6 feet high, and crops freely. As early sorts Early Morn and Daisy are highly thought of, followed by Duke of Albany and Alderman, with Autocrat, Michaelmas, Masterpiece, and The Gladstone for later supplies. The first sowing is made at the end of January in boxes, and outside early in April, with regular successions. Deep digging, plenty of manure, and abundance of space are the salient points to observe, with attention to providing support for the haulm.

POTATOES are considered, and properly so, as quite one of the leading dishes in a collection. Mr. Beckett does not grow a Potato simply on account of its appearance. Duke of York, Snowdrop, and Sir John Llewellyn are the leading early varieties, with Windsor Castle, The Guardian, Yeoman, King

Edward VII., Eightyfold, Reading Russett, Up-to-Date, Satisfaction, Lord Rosebery, Edgemoor Purple, and Purple Perfection to follow. Leaf-mould is a fine addition to the natural soil here for producing clear skinned tubers. The seed is most carefully selected, a 2oz. set is chosen and abundant space provided. The rows are 3 feet apart and the sets half that distance.

RUNNER BEANS have made tremendous strides in popularity as exhibition vegetables during the last ten years. With the advent of the introduction of Sutton's Al variety much was done to popularise this vegetable in the exhibition tent. At Aldenham Lye's Favourite is thought most highly of; shapely succulent Beans 13 inches long are obtained from this variety. In addition Hackwood Success, Ne Plus Ultra, Prizewinner, and Best of All are grown. They reach 13 feet high, which is an indication of the kind of crop produced. The seed is sown in boxes early in May, and the plants are put out in rows 15 inches apart, with the plants 6 inches. An ample supply of manure is added to a deeply-dug trench for the plants in good time to allow it to settle down fully.

CARROTS are exceptionally good at Aldenham this season. It would be difficult to imagine a finer dish than that of Summer Favourite staged at the recent display in the Royal Horticultural Society's new hall. This and Intermediate are mainly grown. A deeply trenched western border is the site chosen. The rows are 18 inches apart, and the plants are thinned to 15 inches. The first week in April the seed is sown for the general crop, and in frames in February for an early supply. In the open a light mulching of old Mushroom bed materials is employed.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

ERADICATING WEEDS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I noted an answer to a correspondent in your paper about a fortnight ago in reference to the eradicating of weeds on lawns. Your reply was to the effect that you had heard of no better way than to cut out the weed or to drop a little poison in the centre of the plant from a brush. We have used with such excellent results on our lawns "the Wikeham Weed Eradicator" that I think it might interest some of your readers to know about it. It is a tubular staff, 36 inches long, fitted with a self-acting valve so arranged that when filled with a reliable weed killer by simply pressing the point into the plant enough liquid is injected to destroy it. We employ women to use it. The weeds turn brown about the second day, and by the fourth or fifth day shrivel up and die. It is so much more effectual and so much quicker than cutting them out that I advise my friends to use it. We get them from the Killet Chemical Company, Liverpool.

G. FAUDEL PHILLIPS.

POTATO AND WHEAT CROPS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I do not at all like to criticise so eminent an authority as Mr. A. D. Hall on matters agricultural, but I cannot allow the suggestion to pass without comment that an acre of wheat is valued at £12. In this county, where wheat growing is considered to be pretty well done, Mr. Hall's estimate is much too high. If the land produces the average crop of one load, ten sacks or forty bushels per acre is considered good. Assuming the

wheat to weigh 63lb. per bushel, it will fetch in the open market £8 per 5qr., or at the most £9 for seed. I frequently hear of 60 bushels per acre crop, but never but once have I grown that quantity, and certainly have not seen it more often. The average yield then is £8 per acre for many hundreds of acres, and is a price which satisfies farmers in this county at the present time. When I tell them of Mr. Hall's estimate they smile. When he quotes the price for an acre of Potatoes at £35 he is certainly nearer the mark; in fact, I should be inclined to put the return a trifle higher.

South Hants.

E. MOLYNEUX.

VICTORIA REGIA IN ROTTERDAM GARDENS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—A week or two ago when in Holland I took the accompanying photograph in the Zoological Gardens at Rotterdam. I think perhaps you may like to publish it in THE GARDEN. I say the

all its privileges. I venture to submit that these outside attractions, as one may well term them, bring into the gardens a great many people who would not otherwise be inclined to go, and, unconsciously perhaps, they receive influences from, and an education in, horticulture and natural history that otherwise they would not get. I have wondered whether it would be possible to introduce into England something of the kind. I know that a great many people are attracted to Kew by the Gardens, which in themselves are beautiful and interesting, no matter how little the visitor may care about horticulture. But, at the same time, it seems to me there are ways in which the gardens might be made even more attractive.

SURREYITE.

[We print this letter, as the illustration is interesting, but we hope the restfulness of the Royal Gardens, Kew, will never be disturbed by a band. It is the one place near London to which those who wish to enjoy the flowers and trees of this great botanic garden can go without disturbance from the blare of trumpets. We recommend our correspondent to take a season ticket for the

VICTORIA REGIA IN THE WATER LILY HOUSE, BOTANIC GARDENS, ROTTERDAM.

Zoological Gardens, but this is hardly correct, for the gardens there are a sort of combination of our Zoological Gardens and our Kew Gardens. From a horticultural standpoint, although there are some interesting plants and houses, I think the Rotterdam Gardens cannot be compared to Kew, and the collection is nothing like as extensive and comprehensive as is the collection of animals and birds, which, in many respects, is superior to our Regent's Park collection. I think, though, there is one feature about the Dutch gardens that is particularly commendable. There is a magnificent concert hall, seating something like 2,000 people I should imagine, in which very high-class concerts are given from time to time, and a full band performs every day. One can sit under the shade of the trees, sipping one's drink, listening to the music, and looking across the beautiful gardens or watching the numberless visitors. The Rotterdam Gardens are not public property, but belong to a society that boasts of a membership of something over 5,000. For something under a sovereign yearly a season ticket can be obtained, which admits its holder at any time to the gardens and

Crystal Palace, or pay a penny for a chair in one of the London parks during band time and take his ginger beer with him.—ED.]

POTATO NORTHERN STAR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Referring to your correspondent's letter in your issue of the 22nd inst., as to the overrated qualities of the above-named Potato, I write to tell you that from 1lb. of Northern Star (three Potatoes), purchased this year, 190lb. were dug up on the 18th inst., and not one diseased. It is quite true this variety continues to grow very late. The Potatoes were grown in a kitchen garden.

LAWRENCE L. SAVILL.

The Woodlands, Chigwell Row, Essex.

RAMBLER ROSES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In the interesting "Notes from Swanswick" in THE GARDEN of the 1st inst. (page 223) there appear some remarks about the poor flowering

FUCHSIA RICCARTONI IN SARK. (Figure to show height of bush.)

of such Roses as Dorothy Perkins and Crimson Rambler. This year in Scotland I do not think the same experience has been general. Dorothy Perkins is not yet so widely grown as to be everyone's plant, as it ought to be, but it has flowered well with me, and in other gardens where I have seen it this year. Crimson Rambler has generally done very well. Aglaia has also done well this year.

Carsethorth, by Dumfries. S. ARNOTT.

FUCHSIA RICCARTONI.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—During a recent visit to the Channel Islands I was struck by the pleasing effect produced by large specimens of this free-growing and beautiful hardy Fuchsia, which in that genial climate attains a great size. The fronts or side walls of many cottages are draped with its graceful sprays of compact foliage and abundant flowers. A photograph of one such cottage, which I enclose, might perhaps be worthy of reproduction in your pages. It is situated in Sark, and is called La Rosée.

H. M. W.

FLOWERS FOR A CHALK PIT.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Few have the good fortune to possess chalk pits or disused quarries for gardening purposes. Suitably furnished, such places become very interesting. The following may be suggestive to "H." (see THE GARDEN for the 15th inst., page x.), who does not state if the pit has only recently been disused or if considerable weathering has taken place. In the latter case, however, weeds will have become established, and, if poor stuff grows, there

pits had shelves here and there, these alternating with almost perpendicular faces, and to clothe these the native Traveller's Joy (*Clematis Vitalba*) was the principal plant used. Several strong roots were lifted from hedgerows in autumn and planted in holes 3 feet deep made with picks. After insertion these holes were filled in with ordinary garden soil. Most of the *Clematis*, however, were raised from seed, sown as soon as ripe in autumn an inch deep in holes in the chalk that had previously been filled with 12 inches or so of good soil. From these seeds plants were produced the next year and trailing shoots the second.

The principal attraction of this plant lies in the feathery awned fruit, this remaining in perfection many months, especially on a vertical face. The plants named previously were also used on the inner sides, together with *Hypericum calycinum*, *H. androsaemum*, and the white Lavender Cotton (*Santolina Chamæcyparissus*). On the floor the Scots' or Burnet Rose (*Rosa spinosissima*) and several garden varieties of it did very well. Where chalk is mixed with earth, or earthy strata runs through it, the filling in of holes with a few spadefuls of soil may be unnecessary. But a little help at the start is a great after-gain in many instances, especially in chalk pits only recently disused. Of course, no special loam, &c., is required, ordinary soil serving the purpose well, and in this instance it was always given. After the roots run through their planting soil they penetrate and appropriate the chalk. Two pretty plants used were *Veronica spicata* and *Aster linosyris*, both uncommon British plants, flowering from September onwards, and delighting in a sunny position. This latter plant is sometimes classed in nurserymen's catalogues with the Michaelmas Daisies, but it is very different

with its unrayed flowers and narrow leaves from the American Asters, and never looks so well in the border as in the rock garden, &c. Its flowers, on wiry stems 12 inches or so long, springing from the chalky crevices, remained bright for nearly two months. As free-growing summer-flowering plants the various species of *Linaria* did well. *L. purpurea*, which I have since seen in thousands on an old and dry castle wall, was very showy with its late spikes of bright purple flowers. *L. repens* is sweet-scented, and reaches only 1 foot in height under arid conditions. A white variety is more recent. *L. vulgaris* (the common yellow Toadflax) and its peloric variety did well. *L. cymbalaria* and *L. C. alba* became too frequent, and are best planted in one spot only.

From out of the chalk Wallflowers sprung with stems an inch in diameter, a thickness needful to support plants 5 feet through. *Antirrhinum majus* was not so satisfactory, but there is little doubt that this position would suit the small creeping *A. Asarina* and *A. glutinosum*. The Sun Roses and Rock Roses are amongst the most satisfactory of plants for any sunny, chalky spots. *Helianthemum canum*, with hoary foliage and bright small flowers, forms very dwarf creeping carpets. It is a native, and should not be forgotten. Many of the smaller *Cisti* are scarcer, but are even more beautiful. *C. formosum* is especially good, with its blotched yellow flowers. *Dryas octopetala*, with spreading carpets of good green, flowered profusely. *Lotus corniculatus* and *Hippocrepis comosa* formed sheets of yellow flowers. But of these Vetches the best for covering surfaces quickly are the various species of *Coronilla*, especially *Coronilla varia*, with rosy flowers, which will even surpass in this respect the *Clematis*, so vigorous are its running shoots. *C. montana* and *C. iberica*, yellow flowered, are always good. *Ethionemas*, *Gypsophila prostrata*, and a form sold in nurseries as *monstrosa* are excellent chalk plants, but should be planted near the eye, as the pink flowers when afar off are not visible against the chalky background.

Plants of *Edelweiss* collected in the Maritime Alps perished, but seed sown in spring on the level portion germinated freely and flowered the succeeding year, the down, as usual on a dry chalky soil, being much whiter than on those in richer soil. The closely related *Antennaria tomentosa* should be planted for its white foliage, *Anaphalis margaritacea* for its late "everlasting" flowers, while several shrubby *Helichrysums* and *Senecio Cineraria* and allied forms will survive the winter in most parts if established in such sites as these. The Alpine *Rhododendron hirsutum* does not dislike chalk, if moisture and a suitable rooty medium can be had. To supply such the holes in planting should be filled in with peat. Chalk often crumbles away, thus if shallow rooting Saxifrages or House-leeks are planted they should be placed on the firmer portions. Another objection to chalk is its whiteness, dryness, and want of form. These one can hardly alter, and to introduce stones, rocks, &c., may make things worse unless very carefully distributed. Another disadvantage arises from the chemical composition which restricts the choice of plants. In an old sandstone quarry, on the other hand, one might, with little or no preparation, grow anything, granitic or calcareous. Among other plants noticed on limestone soils, and which would probably thrive well in a chalk pit, are *Euphorbia Myrsinites*, with prostrate branches and fleshy leaves; *Cotoneaster horizontalis*, red berried, flat spreading branches, and the purple-leaved variety of *Prunus spinosa*. The Italian Bellflower, *Campanula isophylla*, *C. i. alba*, *C. fragilis*, and *C. garganica* all love, in this country, sunshine and warmth, and this applies equally to the shrubby *Globularia nana*, seldom well flowered in our climate.

Royal Botanic Garden, Edinburgh.

CORDYLINE INDIVISA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This handsome Cordyline, of which an excellent illustration appeared on page 261, is not quite so rare in cultivation as Mr. J. Ryan, who supplied

the accompanying note, appears to think. It is represented in several gardens in the south-west, notably at Enys (where there are two fine specimens), Trewidden, Menabilly, and Trellisick. I believe this Cordyline has only once flowered in the British Isles, this having occurred in Mr. Dorrien-Smith's gardens at Tresco Abbey, Isles of Scilly, in April, 1896. An illustration of the plant in flower appeared on page 86, Vol. XLIX. of THE GARDEN. There was formerly a good example in the gardens at Lakelande, County Cork, but since the late Mr. Crawford's death the estate has been sold, and I am unaware if the plant is still in existence.

S. W. FITZHERBERT.

POLYGONUM BALDSCHUANICUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—My experience of the hardness of Polygonum baldschuanicum in accepting any conditions of soil or position may prove useful. I have a plant which grows in a dry and very warm border, and though dormant for about two years after establishing itself, it has made very great growth, bloomed twice this year, and thrown out strong branches in all directions. The blooms have been so abundant that the plant looked like a mass of snow, and made a very pretty effect in my border. The Polygonum planted in a moister situation made an earlier start, but has not grown up so strong and beautiful, nor flowered so abundantly.

Brasted Rectory, Kent.

M. R. RYND.

BELLADONNA LILIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I enclose a photograph of a row of Belladonna Lilies. The Belladonna Lilies are, as you see, under the wall of the hot house, and this year threw up 330 separate stems. Most of them I brought from Madeira in 1864; they have been removed twice. The Farleyense Fern, of which I also send a photograph, has been in our possession since 1869. I was interested in an account you gave of Belladonna Lilies, and this induced me to send an account of ours.

Sandhill Park, near Taunton.

M. PROCTER BAKER.

GARDENING OF THE WEEK.

FLOWER GARDEN.

LAWNS AND LAWN-MOWERS.

WHERE they are bordered by deciduous trees the lawns will now require daily sweeping. In other places worm casts and the various *débris* blown about at this time of year will necessitate the frequent use of the broom. As a rule, horse machines are too heavy for late autumn use, and the final mowings are better done with the lighter hand lawn-mowers. Before the machines are put away for the winter they should be thoroughly cleaned, and such parts as the bearings, chain, knives, &c., well oiled. The machines should then be stored in a dry place, and covered with a tarpaulin or piece of hessian. The lawns should be frequently rolled and the verges cut. The falling leaves demand a deal of sweeping; the main drives, all frequented gravel walks, &c., must be swept almost daily. Further away from the mansion the same prim neatness should not prevail. These leaf-strewn paths have a charm of their own, and during the time of falling leaf are quite in keeping with the season and their surroundings. When all the leaves have fallen these outlying paths should be raked and swept. If not required for making leaf-mould, or to be carted to the brick pits, the leaves should be made into big heaps close by—a few branches of Silver Fir laid on the top will prevent their being blown about—to form a valuable store in case of future need. On no account should leaves be burnt; the amount of ash they yield is comparatively infinitesimal, but decayed, or partially so, they are most valuable either as top-dressing or to incorporate with the soil.

WALKS.

Catch-pits should be frequently cleaned, or a sudden storm may do considerable damage. If there are any weeds to be seen give the paths an application of weed-killer, choosing a fine day after rain.

ARUNDO CONSPICUA.

The plumes are now shabby and should be removed. From June until quite recently this New Zealand Reed has been, except, perhaps, in point of mere size, superior to its relative, the Pampas Grass, which has only now come into flower. The arched plumes of the Arundo are more graceful than the stiffer Pampas Grass, and its looser racemes do not hold so much moisture and get so easily broken. In the colder parts of the country where its hardness is doubtful some protection is advisable, and the Giant Reed (Aruodo doax and its varieties) will also require some protection.

MONTBRETIAS.

These graceful bulbous plants grow so freely that in three or four years they become a tangled mass. It is advisable to lift them every third year, and, selecting the strongest corms, replant.

BELLADONNA LILIES AT SANDHILL PARK.

The old foliage should be left, as it forms a good protection to the tender young growths in the early spring.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

HELLEBORUS NIGER (CHRISTMAS ROSE).

THE flowers of this during the winter are valuable for various purposes. The plants will flower freely in pots, but no attempt at forcing them must be made or probably they will fail to flower at all. Lift the roots from the open ground and place them in suitable sized pots or in deep boxes, in soil of a peaty nature, and afterwards put them in a frame that can be kept close for a time. As they are required for flowering remove them in batches to the greenhouse, where they can have air when necessary, and water in abundance, as well as a little shade. Providing the flowers are fully developed and just beginning to expand they can be assisted to open more rapidly by placing them in warm water in a moderately warm close temperature.

EAST LOTHIAN STOCKS

are now being potted singly into 3-inch pots. They will be grown well on during the winter, and be in flower by April and May next year. After potting place them for a short time in a cold frame and keep close for a few days. They like plenty of light, and should be placed near the glass. When well established they can be removed to the greenhouse shelf. As the plants grow put them into

4-inch and 6-inch pots, and during the winter keep the soil about their roots rather dry, but do not allow them to suffer from lack of moisture. Green fly is sometimes troublesome, but immediately they appear fumigate very lightly with XL All.

GARDENIAS.

Though these plants at any season will bear heat and moisture in abundance, they will develop a firmer and better flowering growth if, during November and December, they are given a temperature of 55° to 60°. On growth of this kind flower-buds will readily form, and there is less likelihood of either thrips or green fly attacking it. The increase of mealy bug may be checked by syringing the plants frequently with petroleum and water, at the rate of a wineglassful of the former to four gallons of the latter. To plants that are well rooted give an occasional dose of liquid made from sheep manure and soot, or sprinkle a little of Clay's Fertilizer on the surface of the pots.

J. P. LEADBETTER.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

PEACHES.

If the roof lights were removed from the early Peach houses the sooner they are restored the better. The trees are now leafless, the wood thoroughly ripe, and the buds forward. The final pruning should be attended to if it is intended to start the trees early. Remove all the old bearing wood that can be spared, and also any very gross shoots. I do not favour shortening back the bearing wood of Peaches and Nectarines unless one side of the tree is outgrowing the other; then pinch out the points of the shoots during the growing season. To destroy red spider or scale the trees should be carefully untied and washed with Gishurst Compound, 4oz. or 5oz. to the gallon. Cleanse the house thoroughly, lime-wash the walls, and top-dress the borders. Tie in the main branches of the tree first, and afterwards the smaller shoots, allowing about 6 inches between each. Young trees should be top-dressed with fairly strong loam, lime rubble, and wood ashes; older trees should have some bone-meal added. Later trees should be lifted and root-pruned before the leaves fall.

THE ORCHARD HOUSE.

The latest trees are cleared of fruit, and should be either top-dressed or repotted. Reduce the soil of those too large to move into larger pots, and return to the same pots, using good fibrous loam, lime rubble, wood ashes, with some bone-meal and soot. See that the pots are clean and the drainage sufficient, make the whole firm by well ramming, and give one good watering before putting the trees outside. The season has been most favourable for the ripening of the wood. They should be plunged at once outside in a sheltered position. See that the pots stand on a firm ash bottom to keep out worms. Before severe frosts occur the spaces between the pots should be well packed with Bracken or litter; then they may be allowed to remain out until required for starting. Give what pruning is necessary then. If very early forcing is contemplated the house should be prepared, so that the trees may soon be placed in position. Select those with plump buds and ripened wood, those in medium-sized pots being preferable. Good varieties of Peaches for pots are Alexandra, Hale's Early, Waterloo, and Condor; Nectarines, Cardinal, Early Rivers, Lord Napier, and Stanwick Elruge. Wash the pots and arrange the trees, keeping the shoots near the glass, so that each tree has plenty of light. Very little pruning will be required, and, unless this is properly understood, it should be deferred until the fruits are set and the young growths are pushing freely.

Impney Gardens, Droitwich.

F. JORDAN.

ORCHIDS.

CLEANING HOUSES.

THIS important work should be proceeded with as soon as possible to allow of all light possible reaching the plants. When washing the outside see that the spouting is blocked, to prevent dirt from entering and contaminating the soft-water tanks.

When starting to wash an interior remove a certain number of the plants to allow the workmen plenty of room. All woodwork, glass, and stages should be well scrubbed, using warm water in which a little soft soap has been dissolved; then see that all walls, ledges, and spaces under pipes are cleared of rubbish and made thoroughly clean before commencing to rearrange. This occasion is favourable for introducing a good system of staging where plants are on inverted pots. On referring to my notes in *THE GARDEN*, February 20, readers will find the system we use described. When rearranging the lightest positions should be given to those Orchids most in need of strong light during the winter months. Plants with growths that require tying should be seen to, and all plants found infested with insects should be cleaned.

SPONGING.

After all the houses have been washed inside and out, every opportunity should be taken to sponge the plants; this is needful at least once a year. Few of our Orchids are sponged more than once a year, but if one becomes dirty it must, of course, be cleaned at once.

LÆLIAS IN FLOWER.

L. anceps, *L. autumnalis*, *L. albidia*, and *L. gouldiana* are now developing their flower-spikes, and every care should be taken to prevent the spikes coming in contact with the glass. Give them the lightest position in the intermediate house where air is freely admitted through ventilators under the stage. It is impossible to grow these Mexican *Lælias* in a stuffy atmosphere. While developing their new bulbs and flower-spikes water will be required when the plants become fairly dry, yet only enough to moisten the compost should be given.

LÆLIA GRANDIFLORA (SYN. *L. MAJALIS*).

This beautiful species has now matured its new bulbs, so no more water will be required till early March. All available light should reach it in the position afforded in the intermediate house, taking the greatest precautions against drip.

Gatton Park Gardens, Reigate. W. P. BOUND.

KITCHEN GARDEN.

SELDOM in Scotland have we enjoyed such a dry and warm autumn. At this date (the 19th inst.) 2° of frost only have been registered in this garden, although a few miles inland it has been much colder. A splendid opportunity has been afforded of giving gardens a thorough cleaning, as the rainfall has been very light. Every advantage should be taken to go over all the ground with the hoe. Improvements and alterations of all kinds should now be carried out, as spring brings so many duties that cannot be put off. The repair or relaying of Box and other edgings should be pushed forward. Manure should be got ready and placed on plots that are to be dug before winter. Lift crops that are now ripe, as this work is much better done in dry weather. Take off yellow leaves from Sprouts, Cabbage, &c. Remove from the garden all stumps, Potato haulms, and other rubbish.

TOMATOES.

To provide supplies during winter and early spring these will require careful treatment. The size of pot should be smaller at the final potting than that used during the summer months. Remove all lateral growths as they appear, and at midday pollinate the flowers. Afford plenty of ventilation when the weather is good. Little damping of the houses will be needed, and the plants should not be moistened overhead. A dressing of a good fertiliser should be given about once a fortnight. If protection has been given to outdoor plants their fruits will continue to develop. They should be gathered as soon as they are of useful size and placed in a warm house to ripen.

CUCUMBERS.

Those intended to supply fruits during winter are now well established. They should not be too heavily cropped in the earlier stages of growth. Allow them to grow strong and sturdy, a night

temperature of 60° being most suitable. Carefully train the plants on the trellis so as to admit as much light as possible. Remove all the male flowers and stunted or deformed fruits. The evaporating pans may be kept filled with liquid manure. This will cause a healthy and clean growth. Slight top-dressing may be given frequently, as the plants increase in growth and vigour. The roof of the house should be washed both inside and out, so that the plants may have full sunshine.

THOMAS HAY.

Hopetoun House Gardens, South Queensferry.

THE INDOOR GARDEN.

DIPLADENIAS AND THEIR CULTURE.

DIPLODENIAS are not so often seen as they deserve to be. They ought to be grown for the sake of their lovely flowers, and they are not so difficult to cultivate as is generally believed. Brazil and Bolivia are the native countries of many species. *D. atropurpurea*, *D. splendens*, *D. Rosa campestris*, and *D. illustris* have handsome foliage as well as most richly-coloured flowers. *D. vincaeflora*, on the contrary, has small and narrow leaves, with flowers somewhat similar to those of the little Periwinkle of our woods. This is rare. I wonder if it is still to be found in botanical gardens. In *D. urophylla* the leaves are large and ornamental; the flowers are as large as those of *D. atropurpurea*. One of the most remarkable species is *D. nobilis*; it was introduced by François de Vos, collector for M. Alexandre Verschaffelt, Gand, in 1847. He found it in the province of Sainte Catherine in Brazil, whence he also brought *Lælia purpurata*. *D. nobilis* well deserves its name for its superb bunches of salmon-pink and white blossoms. One variety, *rosea*, which was introduced at the same time, has its colours more strongly marked.

Dipladenia Harrisii is a species of great vigour, with large golden-yellow flowers. These produce an extraordinary effect when the plant is at the height of its beauty. Benthham called this plant *Odontadenia speciosa*. In *D. crassinoda*, whose blossoms are rose-coloured similar to those of *D. splendens*, the *Echites* genus (from which the *Dipladenias* were separated by De Candolle) reasserts itself. *D. crassinoda* has thicker leaves and its flowers are smaller; they resemble those of the single-flowered *Nerium*. In the older collections there could also be found *D. acuminata*, *D. boliviensis* (introduced by Auguste van Geert in 1869), *D. brearleyana* (1874), *D. flava* (1845), *D. insignis*, *D. amabilis*, *D. eximia*, *D. hybrida*, *D. illustris glabra*, *D. martiana*, *D. Sanderi*, &c. Other species also probably exist. Some *Dipladenias* have a large, woody tuber. *D. acuminata*, *D. amabilis*, *D. atropurpurea*, *D. crassinoda*, *D. Harrisii*, *D. houtteana*, *D. magnifica*, *D. splendens*, and *D. urophylla* do not possess this tuberous stock.

There are two methods of culture, depending on the kind of *Dipladenia*. The tuberous kinds ought to rest completely during the winter; the others, *D. nobilis*, *D. illustris*, *D. Rosa campestris*, *D. vincaeflora*, &c., need much less rest. The stove, or at least the temperate house, is necessary for these plants. When it can be done they should be planted out and the twining stems trained round pillars and on trellises. All hot-house climbing plants are seen at their best under these conditions. The *Dipladenias* do not present the inconveniences of some climbing plants; few insects attack them. A moist, fairly light soil suits them. When planted in pots care must be taken with the drainage, and make the soil firm. Repotting should be done in the spring, and in comparatively large pots in order to avoid yearly repotting. Plenty of light is necessary; they ought not to be shaded except on the warmest days.

In the warm season watering and syringing should be frequent. In winter the species with tubercles should be kept in complete repose; the others should be only moderately watered; in fact, just enough to keep them from withering. When

cultivated in pots they should be trained on light frames, constructed according to the fancy of the grower. One of the prettiest shapes is that of the pyramid; the sphere shape is also very suitable. The propagation of the *Dipladenia* is effected by means of cuttings of half-ripe wood; tender shoots easily perish. Place them in a sandy soil over a moderate bottom-heat in a hot-house. This operation should be effected in the spring, for the tuberous varieties as well as for the others. To prevent insect attacks the cuttings should be steeped in water impregnated with a tenth part of tobacco juice. Seeds can only be obtained by artificial fertilisation. Sow them in March in the hot-house near the glass. Seedling plants will not bloom till the following year.

AD. VAN DEN HEEDÉ in *La Revue Horticole*.

LEONOTIS LEONURUS (THE LION'S TAIL LEONURUS).

THIS plant was grown nearly two centuries ago (1712 to be exact) in the Chelsea Garden, and one wonders why such a showy plant is so seldom met with. From records in old works there is evidence that at one time it was fairly common, more especially on the Continent. A spray of it is figured in *THE GARDEN* of January 24, 1874. Of a semi-shrubby habit, it is a native of South Africa. To a certain extent the cultivator can determine the height of the plants to suit the purpose for which they are required. By rooting cuttings at different times and stopping plants can be had in flower from 1 foot to 6 feet in height. Cuttings root readily in a propagating frame with a gentle bottom-heat. When potted on a very rich soil should be avoided, as a too robust growth is the chief cause of failure in flowering it. After the flower-buds are set stimulants may be given with advantage. To obtain well-ripened growth plants should be placed in the open air during summer. It has, I believe, been tried as a bedding plant. Used for this purpose, the chief point will be to get the plants into flower soon enough, as in the event of early autumn frosts the flowers would soon be spoilt. Under the name of *Phlomis Leonurus* it is figured in the *Botanical Magazine*, tab. 478. The genus *Leonotis* contains about a dozen species, and belongs to the natural order Labiate.

A. O.

MISCELLANEOUS.

TOBACCO GROWING IN IRELAND.

IN an interesting article in the *Irish Times* on this subject a writer states: "The Department of Agriculture had agreed to assist anyone who would experiment with Tobacco culture to the extent of ten acres. Owing to circumstances, for which, perhaps, neither the Department nor any individual agriculturists are responsible, the whole brunt of the experiment fell upon Colonel Everard. He agreed to lay down twenty acres in Tobacco. The Department, for their part, agreed to bear the cost of whatever barn and plant was necessary for the curing and drying of the Tobacco. Thus it came to pass that four suitable areas in the charming lands round about Randalstown, County Meath, were set apart for the experiment. The seedlings were secured in Virginia and Kentucky, U.S.A., and the very best kinds procurable were brought over. They were planted early in the spring, and, suitably treated, they soon sprang into vigorous life and flowering beauty. But when they were within two months of the harvest time no barn had as yet been added to the architectural features of Randalstown. It looked badly for the success of the experiment then. By vigorous strides the work was pushed on, and the barn was completed just in time to receive the ripe harvest of the twenty acres.

"The barn once up and perfectly equipped, the fields were without delay stripped of their Tobacco crop. This had, of course, to be done by stages, as the whole crop could not be treated at once in the barn, ample and excellent though it is.

It was ready for use on September 4, and since then the process of curing, sorting, and drying has been going on continually. It is going on still, and is giving employment to a not inconsiderable number of local hands. With moderate planting the twenty acres have yielded an aggregate of about 14,000lb. weight of leaf. This is a remarkable result for what was practically an initial experiment. It is estimated, however—and indeed proved—that the average yield per acre will be about 1,200lb. of leaf. Good average prices will be forthcoming for this. Dublin manufacturers and experts have priced the samples already grown, and have returned their estimate at as high as 7d. and 8d. per pound. At these figures it is easy to work out a very decided margin of profit, even allowing for the heavy duty to be paid in full.

THE FRUIT GARDEN.

PLUM BELLE DE LOUVAIN.

THIS is one of the most consistent fruiting Plums. It should be grown in every garden. Its fruitfulness is largely due to its early blooming. Plums, like all stone fruits, must open their flowers in advance of the foliage if a good crop of fruit is to follow. When the flowering period is late, thus causing bloom and foliage to unfold

NEW PEAR S. T. WRIGHT.

Natural size. Given an award of merit at the Royal Horticultural Society's Fruit Show on the 14th inst.

together, even though the weather is more genial, most of the blooms ultimately turn yellow and fall off. The above variety is in season here at the end of August, hanging well into September. The fruit is large, of oval shape, and dark purple. It is a first-rate culinary Plum. It does well as a pyramid, but upon a wall with an eastern aspect it does better.

Bishop's Waltham.

G. E.

APPLE BRAMLEY'S SEEDLING.

Soon this late-keeping Apple will get its due share of recognition at the hands of planters where heavy crops are required at a minimum of outlay and little attention afterwards. No variety that I know is more accommodating in the manner of training than this. As a tall orchard standard, a half-standard over a bush, as a hush itself, or as an espalier it is equally good. Its constitution is so vigorous that it will flourish in the strongest clay, and is not liable to canker like many of the large-

fruited varieties. To espalier form it is peculiarly adapted, as the spurs are thickly placed. Its foliage is a dense green colour, giving it a robust and handsome appearance alongside a garden path.

E. M.

PEAR S. T. WRIGHT.

THIS new Pear is the product of Beurré Bachelier and Williams' Bon Chrétien. It is an early variety of good flavour, as may be expected from the intercrossing of two such good sorts. It was exhibited by Messrs. James Veitch and Sons, Limited, Chelsea, at the great fruit show of the Royal Horticultural Society on October 4. It then received an award of merit from the fruit committee.

RED CURRANTS AS CORDONS.

KNOWING how extremely valuable the above fruit is at any time during its usual season, one often wonders why it is not more grown for late autumn supplies. No perishable fruit hangs longer than this after it becomes ripe, if it is kept dry during very wet weather. Old garden lights or shutters answer this purpose well, besides keeping off frost. Nets which must be put on early also help considerably to prevent frost. The site for them should be a wall facing north, or as near this aspect as possible. The border should be well prepared previously by trenching, adding well-decayed manure, with plenty of burnt refuse if the soil is heavy. When the soil is settled prick the surface over and plant in early autumn for preference. In spring they should be cut down to within 6 inches of the current year's growth.

Single cordons, planted at 15 inches apart, will be found far superior to the ordinary bush shapes that are sometimes trained on walls. The fruit is finer and more freely produced, it keeps better, while pruning and summer pinching are carried out far more easily. The aim is to prune hard enough to produce fruiting spurs from bottom to top. Cuttings should be inserted in sandy soil in the open ground. Ruby Castle and Comet are excellent for this purpose.

Hants. G. ELLWOOD.

APPLE RIBSTON PIPPIN.

IN spite of the new varieties of Apples that are added continuously to the list there is still a general appreciation of this old favourite. No doubt the position in which it is growing, and the soil in which its roots are planted, have much to do with its size, colour, and flavour. At Sandringham, where this Apple is much appreciated, huge crops are invariably gathered from horizontally-trained trees planted against a west wall. There it ripens earlier than in the open, has a rich colour, and the warmth from the wall gives additional flavour.

E. M.

RASPBERRY RED MERVEILLE.

THIS is a valuable autumn-fruiting variety. It produces bunches of fruit 9 inches long, six and eight large fruits being ripe at one time. Where Raspberries are required for dessert this is really a first-rate one to grow. For kitchen purposes it is doubly welcome. To ensure success the plants must be pruned hard back the first or second week in March. A better plan is to prune half each

week, thereby prolonging the season of fruiting. The last pruned ones fruit on the current year's growth. Here this plant grows from 3 feet to 4 feet high, with fine strong growth.

Bishop's Waltham.

G. ELLWOOD.

INSECT PESTS.

APHIDES OR PLANT-LICE.

A LEAFLET has been issued by the Board of Agriculture and Fisheries as follows: Nearly all plants, in garden and field, and under glass, suffer from the ravages of aphides. These universal pests are most common in temperate climates, but even in the tropics whole crops are ruined by them. The aphid enemies of many crop and ornamental plants are very numerous in species. The aphides themselves are known by a great variety of names, such as green and black fly, smotherers, and dolphins, while the disease they produce is sometimes termed "blight."

They belong to an order of insects called hemiptera, which are provided with a mouth used for sucking and capable of piercing the structures of plants, upon the sap of which they feed. They undergo what is termed an incomplete metamorphosis, that is, there is no quiescent chrysalis (pupal) stage, and they feed throughout their whole existence.

They damage plants in a twofold manner, first by sucking out the sap and so weakening the vitality of the plant; and, secondly, by interfering with the functions of the foliage leaves by blocking up the stomata (or breathing pores) of the leaves with their excreta. This excreta is not only of the ordinary kind, but also consists of a sweet gummy substance called "honey-dew." This substance is passed out through two tubes, called "cornicles," situated on the back of the aphides. A few aphides such as the woolly aphis have no cornicles and produce no honey-dew. The skin of the plant-lice is provided with numerous glands which secrete either a waxy substance that covers the skin (Rose aphis, Bean aphis, &c.) or dense woolly masses (Woolly aphis, &c.). In both cases the excreted substances have the power of throwing off water and so keeping the insects dry.

Life History.—Aphides may be winged or they may be wingless; as a rule winged and wingless generations occur in each species.

The multiplication of aphides is very rapid, owing to the shortness of the time necessary for the young to attain the power of reproduction. Aphides not only breed in the ordinary way, but females may also, without any males being present, produce eggs which can develop, or they may produce live young. Some aphides live only on one kind of plant, the Rose aphis (*Siphonophora rose*) for instance; others live on two plants, which may be of different natural orders, migrating from one to the other, as the Hop aphis (*Phorodon humuli*) which migrates between the Hops and the Prunes; others live on several plants, as the Bean aphis (*Aphis rumicis*), which may be found on Beans, Peas, Docks, and Furze.

Some kinds, as the Rose aphis, attack leafage and shoots alike; others, as the Bean aphis, may even attack the fruit (pods); others the stem and twigs (woolly aphis). Not only may plant-lice migrate from plant to plant, but some can live both above and below ground, and may migrate from root to trunk or root to foliage (as the *Phylloxera* of the Vine and the woolly aphis of the Apple).

A typical life-history of an aphis may be as follows: The adult female or "Mother Queen" is wingless, and produces without the agency of a male, not eggs, but living young; these young in a short time resemble the wingless parent, and can themselves produce living young. This viviparous reproduction, where only females are present, can go on for many generations. Should a plant be covered with these aphides, and their food become scarce, winged females may be produced, which fly off to other plants and there deposit living young. Towards the end of the year, as cold comes on or food becomes scarce, males as well as females are

produced; these may be either winged or wingless. These females, after being fertilised, deposit eggs at the base of buds and on the stems, leaves, &c., of plants. These eggs remain over winter and hatch into the larvæ that become the "Mother Queens," with which this account of the life-history started. Some plant-lice live entirely during the winter in the egg state (Bean, Pea, Plum aphid, &c.), others mostly as insects, a few eggs only occurring (woolly aphid).

The effect of weather on aphides is very great. Dry, hot and sultry weather is favourable to them; the same conditions check the growth of the plant, and so the plant-lice soon overcome it. An excessive quantity of manure, especially nitrogenous manure, also predisposes the plant to aphid attack.

Remedies.—Aphides can easily be destroyed by spraying the affected plants with a soft soap wash. This is made by dissolving from 6lb. to 10lb. of soft soap in 100 gallons of soft water. The soft soap blocks up the breathing pores of the plant-lice and so kills them. Quassia is sometimes added;

used in the bee-keepers' "smoker," is said to be a very good remedy for green fly, and does not injure the most delicate flowers.

In all cases the aphides must be attacked as soon as an invasion shows itself, especially when the species of aphid has the habit, like the Plum aphid, of curling up the leaves and so of protecting itself.

Natural Checks.—Several insects prey upon aphides, and should be encouraged. The chief of these are ladybirds and their larvæ (Coccinellidæ); hover fly maggots, which are the larvæ of the Syrphidæ; the larvæ of the lace-wing or golden-eye flies; and various minute Hymenopterous parasites (Chalcididæ), which lay their eggs in the bodies of the aphides, and whose maggots destroy them.

Man cannot, however, rely solely on the services of these beneficial creatures, but must check the increase of the aphides by washes as soon as they appear upon his plants.

Fighting the Hollyhock disease.

Messrs. Webb and Brand, Saffron Walden, the well-known Hollyhock growers, write: "For the past thirty years the Hollyhock has been the victim of a virulent form of disease (*Puccinea malvacearum*), which has wrought great havoc amongst them by destroying their foliage and rendering them very unsightly just when they are coming into flower. This has baffled many in their attempt to grow them. In order to check the spread of this fungus we recommend the following remedy, which we have used in our nursery with satisfactory results. To 1lb. of Tobacco powder add a quarter of an ounce of finely powdered sulphate of copper, well mixed, dust the under surface of the foliage (or wherever attacked) with the powder every two or three weeks during the growing season. Choose a dull, still day for the operation; this will be found effectual." Should there be any difficulty in procuring the mixture, we can supply it direct in 1lb. packets, price 1s. 6d. each.

The late Mrs. Whytock.—Much sympathy is felt for Mr. James

Whytock, gardener to the Duke of Buccleuch, at Dalkeith Palace, on account of the deep bereavement he has sustained by the death last week of Mrs. Whytock. Many who have enjoyed the hospitality of Mr. and Mrs. Whytock will hear the news with regret.

Chrysanthemums at Dumfries.

There is at present on view in the Corberry Nursery of Messrs. James Service and Sons, Maxwelltown, Dumfries, a fine collection of Chrysanthemums grown for large blooms, and mainly intended for exhibition. They comprise a number of the new French varieties, as well as the best of the older Chrysanthemums which have proved satisfactory in the south-west of Scotland. They are placed in two large houses, and, although the

collection as a whole is not fully in flower, a number not being required until November, there are many flowers of great size and quality, while those not in bloom or not fully open are giving great promise of splendid flowers. Amongst those observed and noted as giving excellent blooms fit for competition are *Souvenir de Calvat père*, *Erienne Bonneford*, *President Vigers*, *Godfrey Masterpiece*, very fine, *Miss Mildred Ware*, *Miss Elsie Fulton*, *Sensation*, *Loveliness*, and *Mrs. J. J. Lewis*.—S. A.

Consumption of wine in Britain.

—In their report to *The Times* upon the 1904 vintage, Messrs. W. and A. Gilbey state: "Notwithstanding that the interest of our nation in the subject of wine generally is probably greater to-day than at any previous period, and that any information on vintages or wine-growing is eagerly sought, it remains a fact, in contrast, that, be the cause what it may, the consumption of wine in the United Kingdom continues steadily to dwindle, regardless of our great increase of wealth, and we are consuming actually less wine than we did thirty years ago when the population was some 35 per cent. less. Not only France, but almost every wine-producing and non-wine-producing country of Europe have increased their consumption of wine from year to year in proportion to their population and increasing wealth, with the almost sole exception of the United Kingdom." Messrs. Gilbey attribute this fact chiefly to the heavy wine duties.

Tea Rose Corallina.—This is one of the brightest, freest, and best formed of the Tea Roses which bloom in autumn. It was raised by Messrs. W. Paul and Son, of Waltham Cross, and distributed by them two years ago; the buds are long-pointed and finely formed, and the flowers are produced in the greatest profusion, especially in autumn, as the fine bunches of this variety exhibited at the recent meetings of the Royal Horticultural Society's show. It is particularly striking in the collection of dwarf Roses growing in the Norfolk Nurseries, Dereham, by Mr. John Green, and the eye could rest upon many plants of it laden with blossom. It is appropriately named, for there is a peculiar shade of coral rose deepening to crimson in the flowers, which makes it so attractive. The Waltham Cross firm have distributed many valuable Roses, but as an autumn bloomer it would be difficult to name one which surpasses *Corallina*.—R. D.

Turriff Horticultural Society.

—At an adjourned general meeting of this society, held recently in the Town Hall Buildings, Turriff, Mr. Stewart, chairman, presiding, a report of the state of the funds was submitted by the treasurer, Mr. A. Burns, sen. This showed receipts amounting to £77 12s. 5d., with an expenditure of £45 16s. 10d. This gave a balance of £31 15s. 7d. with which to pay the prize money; but as this sum was only about the half of what was anticipated, the members agreed to take only half of their prize money. A proposal was made by the Rev. E. S. Gunson to alter the date of the show; but, after considerable discussion, this was remitted to a committee to consider it further and to report to a general meeting to be held in the spring. The financial results of the year are disappointing; but it is hoped that the falling off in the income is only a temporary one.

Lagerstrœmia indica at Abbotsbury.

—It may interest you to know that we have at Abbotsbury a specimen of the above about to flower outdoors. It is unusual for it to flower outdoors, but I believe it flowered here about four or five years ago. The specimen we have here is 16 feet to 18 feet high, and on a south wall. When it was originally planted it was evidently intended as a climber, but it has grown above the wall several feet, and is now flowering almost at the extreme end of the growths. It is partly sheltered from the southerly gales by *Eucalyptus globulus*, which is 40 feet to 50 feet high, and *Evergreen Oaks*, which may account for it. I might say it is also partly sheltered by the rather rare conifer *Fitzroya patagonica*. When the spikes are developed I hope to send one to you for your table, and if particularly good I intend having it photographed.—H. KEMFSTALL, *Dorchester*.

CHINA ROSES AND IVY IN NOVEMBER.

this acts as an astringent to the leafage and cleans it of the honey-dew and excreta formed by the aphides. For black fly on Cherry, and for all those that produce a copious flow of honey-dew, it is a most useful ingredient. The Quassia chips are boiled and the extract added to the soft soap wash; 6lb. to 8lb. of chips are required to every 100 gallons of wash. Paraffin emulsion, an excellent spray against aphides, is necessary for some kinds, as woolly aphid, which may also be attacked in winter by caustic alkali wash. For those which attack the root it is best to use bisulphide of carbon injected into the soil, a quarter of an ounce to every 4 square yards. Care must be taken with this substance, which is both poisonous and inflammable. The vapour of bisulphide of carbon liquid,

[NOVEMBER 5, 1904.]

HOME-GROWN FRUIT.

IT is safe to predict, that notwithstanding the unusually good crop of fruit announced from all parts of the country this year, fruit from the colonies and abroad will be just as much in demand as ever after Christmas. And this is chiefly due to a lack of proper means and a want of knowledge among home growers as to the best methods of storing. The Board of Agriculture and Fisheries has published much useful information upon these subjects by means of pamphlets, but they do not seem to have achieved the results they deserve. If all the good fruit that is produced in British orchards, gardens, and fruit farms were sent to market in a suitable condition for eating, and attractively exhibited, the home grower would find that his land would yield a much better profit than now is the case. There is no question as to the superior flavour of our own produce over that received from abroad. An instance of this was furnished by the exhibit of Apples from the Agent-General for British Columbia at a recent meeting of the Royal Horticultural Society. Although the society awarded its gold medal to the collection, this could not have been for good flavour, for they were not to be compared in this respect with hundreds of home-grown fruits in the hall. Considering the distance they had travelled, 3,000 miles by rail and 3,000 miles by sea, their appearance bore testimony to the skilful gathering and packing they had received, and probably they would have fetched fairly good prices in the market.

The fact that home-grown Apples hold the market until Christmas speaks well for their quality, and there is no doubt that if we were able to offer as good Apples after Christmas as we do before, we should have less reason to complain of the large supplies imported. We have an enormous advantage over the foreign grower in that we can market our Apples and Pears before their flavour is impaired, and if the public cannot yet distinguish between a good home-grown Apple and one that has lost all its flavour and nearly all its value as a fruit, they would soon do so if opportunities were offered. But at present home-grown fruit is comparatively rarely seen on the market early in the year. We are learning, if slowly, how to produce the best fruit, and the value of planting the best varieties. But until we have also learnt how to store fruit until a favourable opportunity offers for its disposal, so long

shall we have an abundance, sometimes a glut, of home-grown produce before Christmas and practically none afterwards, thus creating a demand for supplies from abroad.

In the Agricultural Returns for last year more than 7,000,000 cwt. of fruit were imported, and of these 4,500,000 cwt. were Apples. The total cost of imported fruits was £6,468,800, that of Apples alone being £2,781,643. These figures serve to show what a field is open to the British fruit-grower. With the great advantage he has in being on the spot, he ought, if skilled and up-to-date methods were employed, to be able easily to prove superior to competitors on the other side of the world. The close of an exceptionally good fruit season is a fitting time to remind growers of the need for adopting the best methods of culture and storage, and of putting to practical use the results of scientific experiments, so as to be able to take full advantage of the opportunities at their fingers' ends.

IMPORTED v. ENGLISH-GROWN APPLES AND PEARS.

ENGLISH APPLES ARE THE BEST.

THE interesting exhibit of Apples and Pears grown in British Columbia and exhibited at the Royal Horticultural Society's hall on the 18th inst. by the Agent-General for that colony, attracted much attention from growers and visitors by their large size and brilliant colour. The collection served to show conclusively the great possibilities of the soil and climate of that part of the world for producing large and well-coloured fruits. It speaks well also not only for the skill with which they were packed, enabling them to be delivered in London in apparently such excellent condition after travelling about 6,000 miles by sea and rail, but also for the courage and public spirit exhibited by the growers and agents of the colony in venturing so far to place them in competition on the market of a country which boasts of being the best Apple-producing country in the world. Comparisons, I know, are often odious, but when a fine exhibit of imported hardy fruit such as this was shown in England, and at a time so little removed (only a fortnight) from the great show of British-grown fruit held in the same hall, the occasion presents an opportunity for comparison as regards the quality of the home and imported article, which it would, I think, be regrettable to let pass by without comment.

The chief varieties comprising the imported collection were standard sorts well known in England, such as Ribston Pippin, Wealthy, Golden Reinette, Warner's King, Gravenstein,

King of Tompkin's County, Northern Spy, Blenheim Orange, and Emperor. An Apple, little, if at all, known in England was a variety named Wolfe River, a fruit of immense size, and of a deep vermilion colour. A large dish received a cultural commendation (in addition to the society's gold medal awarded to the whole collection).

Judged from a popular point of view as to colour and size, the public verdict, no doubt, would be in favour of these fruits as against any out of door English fruit exhibited at the show mentioned; but no judgment as regards fruit can be less reliable than that of the ordinary public, carried away as it always is by that which is imposing in size and brilliant to look upon and pleasing to the eye. It is a truism amongst growers that size and colour are no indication of quality or richness of flavour; indeed, it is often a proof of the reverse, even in imported Apples, as the best flavoured varieties imported are undoubtedly Newtown Pippin and New York Pippin, both distinctly pale varieties, with little or no colour. It seems a fortunate coincidence that this national show of hardy fruits was held by the Royal Horticultural Society a fortnight before these fruits were seen, so that comparison as regards their value and quality with English-grown fruit was made possible for members of the fruit committee, who had the privilege of adjudicating on both occasions. A magnificent collection of Kentish-grown Apples and Pears was exhibited by Mr. G. Woodward at the same show, making the possibility of comparison more satisfactory and conclusive still. In rich colouring there is no doubt that British-grown fruit is wanting as compared with imported fruit, and possibly a little in size; but as regards the more solid and valuable qualities of weight, texture of flesh, and flavour, the British-grown fruit has proved decidedly and far away the best, and this is especially the case with those varieties of Apples and Pears which are in season from August to the end of January. I am speaking of dessert varieties. The quality of the imported fruit was thoroughly tested by the fruit committee by tasting. As regards the texture of its flesh and the quality of its flavour it proved most disappointing. The flesh of the Apples was sleepy and without a vestige of juice. As regards flavour (which probably at home would be all that could be desired) it had completely vanished, without exception. There was not one tasted at the table that one would care to have a second bite at. The few Pears tasted were rather better than the Apples. The best samples were Beurré Diel and Beurré d'Anjou, but the collection no doubt was a failure, judged by the standard of a good fruit, namely, quality, texture of flesh, and rich flavour.

The conclusion drawn regarding the relative merits of home-grown and imported fruit in the case under notice is that home-grown Apples and Pears grown by experts in their

cultivation on suitable land in England can hold their own against such fruit from any other country. This should go far to inspire our landowners and cultivators with confidence to embark still further in this important industry.

OWEN THOMAS.

PLANTING FOR WINTER EFFECT.

AN instructive paper was read by the Hon. Vicary Gibbs on this important subject before the Royal Horticultural Society on Tuesday last. We can do no more now than refer to a few of the leading features.

One point was strongly insisted upon, and that the close pruning of certain trees and shrubs to get the full colouring of leaf and stem, and Mr. Gibbs pleaded for a fuller recognition of the autumn beauty of many species. The common Snowberry (*Symphoricarpos*) was mentioned as a shrub improved by hard pruning in spring, the result of this being a greater profusion of flowers and fruit, and other shrubs named as benefiting by this treatment were *Spiræa Douglasi* and *Cornus sanguinea*. Among the shrubs named for planting for autumn effect were *Pyrus arbutifolia*, the Spindle tree (*Euonymus europæus*), *Rhus Typhina*, *Rosa rubifolia*, *R. rugosa*, *Leycesteria formosa*, *Kerria japonica variegata*, and *Fuchsia Riccartoni*, which is a shrub generally considered tender, but though the stems suffered, Mr. Gibbs had never known the roots killed, even in the clay soil at Elstree. *Bambusa Metake* produces suckers very freely at Aldenham, and a large group died last year through flowering. Every tiny shoot flowered, and no growths came from the roots. The Sea Buckthorn (*Hippophaë rhamnoides*) was mentioned as a shrub for the inland garden, although it is a native of the sea coast; the fruit is not touched by birds. Of late-flowering shrubs mention was made of *Olearia Haastii*, *Spartium junceum*, *Desmodium penduliflorum*, *Colletia spinosa*, *Ceanothus americana*, and *Caryopteris Mastacanthus*. Very beautiful as single specimens for their autumn leaf or stem colouring are *Taxodium distichum*, *Liquidambar styraciflua*, the Maples, especially the Sugar Maple (*Acer saccharinum*), *Disanthus cercidifolium*, *Enkianthus japonicus*, the variegated Blackberry, *Amelanchiers*, and Anthony Waterer's variety of the American Oak (*Quercus coccinea*). Mr. Gibbs also referred to the beauty of certain trees for their autumn tint. At the moment of going to press we cannot refer further to the interesting paper, but we hope to reproduce it when it appears in the Society's Journal. A remarkable collection of shoots from Aldenham was displayed in the hall.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

November 5.—Batley and District Chrysanthemum Show; Loughborough Chrysanthemum Show; Penarth Chrysanthemum Show; North Lonsdale Chrysanthemum Show.

November 8.—Ipswich and East of England Horticultural Society's Show at Ipswich (two days); Dulwich Chrysanthemum Show (two days); Sevenoaks Chrysanthemum Show (two days); Dulwich Chrysanthemum Show (two days).

November 9.—Buxton Chrysanthemum Show; Southend Chrysanthemum Show (two days); Stoke Newington Chrysanthemum Show (two days).

November 16.—Liverpool Horticultural Association Chrysanthemum and Fruit Show (two days).

"In Cyderland."—Those who were present at the private performance of this pretty musical play at the Cripplegate Theatre, Golden Lane, London, some months ago, will welcome a repetition of it in aid of the Gardeners' Royal Benevolent Institution. The play is called "In Cyderland," and has been thoroughly revised. The performance will take place in the same theatre on Thursday, November 24, beginning at 8.15, and tickets may be obtained from the hon. secretary (Mr. F. A. Washington) of the "Hurst and Son" Musical Society, members of which form the orchestra, or from the secretary of the institution, Mr. G. J. Ingram. An early application for seats is necessary. The libretto is written by Mr. R. Carey Tucker, and the music composed by Mr. Edward Sherwood, son of Mr. N. N. Sherwood, the head of the famous firm of "Hurst and Son." It is pleasant to see that the great example of the father is followed by the son. It will be remembered that only recently Mr. N. N. Sherwood gave £1,000 to gardening charities, to be divided between the Gardeners' Royal Benevolent Institution and the Gardeners' Orphan Fund. Mr. E. Sherwood is showing the same sympathy and interest in distressed gardeners and their widows. The performance could not be given in a better cause.

Vitis Thunbergii.—This vine is undoubtedly the most ornamental and brilliant of its race. Here it is far superior in every way to the *Coignetia*, so much admired of late years. It is even more vigorous, and has larger leaves, which attain a length of 1 foot and of proportionate breadth. I put in a small plant in the spring of 1903, pruned it hard back last spring, and it has made growths 14 feet long. This is a great advantage where walls, poles, or pergolas are required to be covered quickly; then to be rewarded in autumn with foliage of brilliant scarlet and crimson hues. It is a most desirable plant for autumn tints. It will, I feel sure, find favour with all lovers of climbing plants when better known.—G. ELLWOOD, *Swanmore Park, Bishops Waltham.*

The Langley Bullace.—Both Mr. G. Wythes and I have strongly advised Messrs. J. Veitch and Sons to give this really fine late autumn cooking Plum a much better name. To describe it as a Bullace is absurd. The fruits are as large as those of Rivers' Prolific Plum, are of rounded form, deep purple in colour, very fleshy, and of pleasant flavour. It is really a Plum, as its parentage, Farleigh Damson and Black Orleans Plum, indicates. When shown before the fruit committee two years ago the fruits were not fully developed. This year the seedling tree is more matured, and the fruits have been very much larger. It was unfortunate the Press representatives did not see the remarkable clusters, fifteen to twenty fruits on a bunch, shown on the 18th ult., before they had come before the committee. Because of its remarkably fine appearance a first-class certificate was unanimously awarded to the Plum.—A. D.

The Grappenhall Lavender.—Lavender is deservedly a favourite plant, and those who are unable to grow it in their gardens are frequently heard to lament its absence. I should like to mention the fine variety sent out a year or two ago by Messrs. Clibran, of Altrincham, under the name of Grappenhall Lavender. It was claimed for it that it was superior to the common Lavender, and this year's experience of it confirms the claim made for it by the vendors. My plants did not bloom last year, probably on account of their removal, but this season they have flowered for a long time, and their large spikes of flowers are superior to those of the common form. Nor is this gained at the expense of fragrance. It has broad foliage also, and is altogether a plant worthy of being cultivated by all who care for these fragrant herbs. Like the other Lavenders, it prefers a dryish soil.—S. ARNOTT, *Carsethorn, by Dumfries, Scotland.*

Irish railways and farm produce.—Many of your readers are doubtless interested in the announcement made by the Great Northern Railway, England, offering special facilities for introducing sellers of farm produce to consumers. In this matter one Irish railway (Great Northern) have been the pioneers in Great Britain. As far back as 1896 this company

inaugurated a system of special rates for conveying farm and gardening produce, and have even gone to the trouble of providing special packing hampers at a nominal cost. Names and addresses of sellers and buyers are kept on record and periodically revised. This information is supplied free to bona fide enquirers. The following figures will give an idea of advantageous rates of conveyance. By passenger train small consignments of eggs, butter, cheese, flowers, fruit, vegetables, meat, &c., from any station on the Great Northern Railway to Belfast, Dublin, Derry, Lisburn, Bundoran, and Warrenpoint, 26lb. to 30lb. up to 100 miles 6d., 56lb. to 60lb. up to 100 miles 1s., and so on embracing weights from 11lb. upwards. This rate includes free delivery inside company's free delivery boundary. Last year the company carried 23,448 boxes under this regulation. Special provision has also been made for carrying milk. Sixteen gallons for 100 miles at 1s. 4d. or 1d. a gallon, the carriage of returned empty can included. Last year they carried 43,390 cans. This company have also specially constructed fruit vans. Apples and Pears from Annaghmore, County Armagh, to Dublin are conveyed at 15s. a ton, to Belfast at 8s. 6d. a ton.

A note from Ockley.—An old Bay tree, growing in a sunny corner of my garden, is now wreathed with the white blossoms of *Solanum jasminoides*. Long sprays of this lovely climber hang from the top branches of the old tree some 20 feet high, and are especially beautiful at sunset, the dark Bay leaves forming such a good background to the *Solanum*. A satisfactory feature in the garden this summer has been a border of mixed *Scabious*, which has been in blossom since the beginning of July, and is still full of flowers and buds. My *Roses* are doing well this autumn, the two which continue to flower best being *Mme. Alfred Carrière* and *Corallina*. The *Aponogeton*, after flowering well in a pond during July and August, has had a month's rest, and is now in flower again. A Cape Silver bush (*Leucodendron argenteum*), which I planted from a seed five years ago, is now nearly 7 feet high, and has many side branches covered with silvery downy leaves. I should be glad if someone would kindly tell me whether I may expect it to flower in my cool greenhouse and what sort of flower the Silver bush bears.—R. LYELL, *Ruckmans, Ockley.*

Eupatorium weinmannianum.—This *Eupatorium* is generally treated as a greenhouse plant over the greater part of the United Kingdom, but in the south-west is thoroughly at home in the open air, in that district forming huge bushes 10 feet in height and as much through, and flowering profusely from October onwards, blooming freely until Christmas unless a severe frost, which is rare in that district before the new year, should injure its blossoms. Its bloom-corymbs, composed of numberless small white flowers, are flat about 4 inches in diameter, and are borne in such profusion that the bush appears entirely covered with flower. The blossoms have a pleasing fragrance, and are followed by fluffy seed-vessels which are not unattractive. After the flowers of *Escallonia montevidensis* or *floribunda* are withered such butterflies as are about resort to the blossoms of this *Eupatorium*. If allowed to grow naturally it forms a dense bush, every shoot of which is terminated by a flower-cluster. It has often been confounded with *E. odoratum* or *odoratissimum*.—S. W. F.

An experiment in Apple growing.—An interesting experiment in grafting has been the source of much interest in the neighbourhood of Beaulieu, N.B. About three years ago Mr. James MacIntosh, carpenter, Beaulieu, who had an arch composed of two Mountain Ashes over one of his garden paths, grafted a scion from an Apple upon one of these. Last year the appearance of the graft showed that it had been successful, and this season Mr. MacIntosh was rewarded by seeing a crop of nine Apples of large size and of unusually fine colour. A curious feature is that the Apples have a flavour slightly resembling that of the berry of the Mountain Ash. A number of people visited Mr. MacIntosh's garden to see his Apples grown in this way, and depending from an arch composed of Mountain Ashes.

Cupressus lawsoniana erecta Allumil.—Among glaucous-tinted conifers few are more beautiful than this variety of Lawson's Cypress. Its habit of growth is close and columnar, and is vigorous and free. A selection of this distinct variety of Lawson's Cypress, planted wide enough apart for free development, would be an exceedingly effective feature on the lawn.—E. HOBDAY.

Primula stellata.—This will be useful to the floral decorator, as there is a demand for light flowers of loose habit for vases, especially for dinner-table decoration. Though just as easily grown as the other forms of the Chinese Primula, this plant has a taller growth, and the flowering stems are longer. For cutting purposes this adds to their value. It is not likely to make a market plant, for the man in the market does not deviate much from old standards; but there is a time coming, I think, when a demand will arise for something fresh, and the stellate Primulas, Cinerarias, and other plants of similar habit will be wanted.—E. HOBDAY.

Cineraria stellata.—Though its habit of growth does not exactly meet the views of the man in the market just yet, it is a valuable plant for the conservatory, and the flowers, by reason of their lightness and length and stiffness of the stalks have some value for cutting, and one plant, when well grown, produces sprays for cutting for a long time in winter and early spring. Seeds are abundantly produced and grow freely, and the seedlings, in all stages of growth, possess more vigour than the old-fashioned Cinerarias. Last spring some of our surplus plants were turned out on the north side of a wall, where they continued to flower and scattered their seeds, and every seed grew. I have had the same thing carried out years ago with Cinerarias, and have come to the conclusion that sowing such things in heat, except for very early flowering, only weakens the progeny. When shifting on into 8-inch or 9-inch pots very large plants are produced that will be covered with flowers; there is now much variety in colour, and, by selecting the best plants for seed purposes, we may reasonably expect improvement.—E. HOBDAY.

Discovery of fruit-fly parasite.—Mr. A. Sanderson, Chislehurst, sent an interesting account to a recent meeting of the Scientific Committee of the Royal Horticultural Society of Mr. G. Cowpere's discovery in Brazil of the parasite of the fruit-fly, well known as a devastator of orchards in South Africa, Jamaica, Bermudas, Italy, Spain, and Southern France, as well as Malta. After two years travel and search with no success, he finally discovered it in Sao Paulo, and succeeded in conveying it alive, by rendering it torpid by the refrigerator, to Australia. A difficulty arose in the seasons of Brazil and Australia not coinciding, so that Mr. Cowpere is feeding them artificially till the fruit season comes round. He found several other parasites, as of the black scale, which has revolutionised the treatment of the pest in California, where its success has convinced even the most sceptical. Mr. Cowpere secured a second parasite of the black scale in Brazil. He discovered also the codlin moth parasite in Europe.

Leonotis Leonurus.—Judging by the remarks overheard at the last meeting of the Royal Horticultural Society, when some fine specimens of this bright coloured Labiate were shown by Messrs. Veitch, it would appear to be little known. It is a native of Cape Colony, and though the actual date of its introduction seems doubtful, this Leonotis was cultivated by Philip Miller in the Chelsea Botanic Garden as long ago as 1712. After a time, however, it would appear to have been lost, and for its reintroduction into this country we are, I believe, indebted to Mr. Lynch, who found it in the Ghent Botanic Garden about the year 1880, and secured it for the garden at Cambridge. Not long after the date just mentioned I saw it in good condition with Mr. Cannell at Swanley; in fact, it was my first introduction to the plant in question. Though I have often seen it since then at Kew it has never been much grown, and for its present revival we must thank Messrs. Veitch, who have of late years done so much towards lifting many good plants out of obscurity—Jacobinia

chrysostephana as an example. This Leonotis is of rather tall growth, the upright, growing shoots being clothed with narrowish leaves of a soft, hairy texture, and about 3 inches long. The flowers, which are borne in whorls on the upper parts of the shoots, but not quite to the top, resemble both in shape and arrangement the Dead Nettle of our waysides, but their colour is a bright orange-scarlet, and a considerable number of flowers are borne in each whorl. They are clothed on the outside with short hairs. It is readily propagated from cuttings of the young growing shoots put in during the spring months. The plants should be placed out of doors in a sunny spot throughout the summer, and taken into the greenhouse when the early autumn nights get cool. If the atmosphere is too dry red spider is sometimes apt to attack the foliage, but its worst enemy within the London district is a dense, sulphur-laden fog, which plays havoc with the tender leaves. In brighter and warmer climes than ours it is a gorgeous and popular plant.—T.

Institution of Heating and Ventilating Engineers.—At the meeting of the Institution of Heating and Ventilating Engineers

CHINA ROSES IN NOVEMBER.

(From a photograph taken in Messrs. Marshall's Barnham Nurseries, Sussex. See page 316.)

(Incorporated), held at the Holborn Restaurant, London, on the 18th ult., Mr. George Crispin (of the firm of James Crispin and Sons, F.R.H.S., heating engineers, &c., Nelson Street, Bristol) was unanimously elected as president for the forthcoming year. The summer meeting of the institution will therefore be held at Bristol in July, at the invitation of the president; and it is expected that the major portion of the members, numbering over 220, will then be present. The Institution of Heating and Ventilating Engineers is composed of the leading engineers in the trade throughout the United Kingdom, and Mr. George Crispin is to be congratulated on being selected to fulfil such an honourable position. The last summer meeting was held in Liverpool, and other summer meetings have been held in Nottingham, Birmingham, Dublin, Stourbridge, and London, at the invitation of the previous presidents who have been residents in these cities.

Dye from Echium.—Dr. Plowright sent specimens and the following communication to a recent meeting of the Scientific Committee of the Royal Horticultural Society: "For some years past I have been endeavouring to obtain specimens of *Lithospermum arvense*, in order to test its colouring properties; but I have neither been able myself to meet with specimens, nor have I been able to obtain any from my friends. At the suggestion of Mr. G. M. Holmes, I examined the roots of *Cynoglossum officinale* and *Echium vulgare*. In the first named I failed to detect any colour, but in the last named certain specimens contain alkanin in appreciable quantities. As is well known, *Echium vulgare* favours sandy soils, and it is often a brilliant ornament to our sandy lanes and barren places on heaths, &c. At times it strays into cultivated light land. I have examined specimens from five localities near King's Lynn, in three of which the *Echium* roots were devoid of red colour, excepting, perhaps, the barest trace. In the other two the colour was developed in more or less extended patches on the main and secondary roots. The age of the plant does not seem to have much effect upon its production; but, if anything, it is more abundant in the biennial plant. The two localities which produced it in greatest quantity had this in common. They were both almost pure sand, but received the washings from the main road made of imported granite. In fields, whether manured or not, and in ordinary sandy habitats, the roots were devoid of colour. So were specimens growing on roadsides where any flint was employed as road metal. The probable explanation is that the disintegration of the granite yields an appreciable amount of potash. The alkanin is confined to the cortex, as the accompanying figures show. It is deposited in the cell walls in a more or less patchy manner. By treatment with caustic potash the red cells are changed to bright blue. The coloured parts of the roots were treated with spirit of wine and oil of turpentine, both of which dissolved out the alkanin. Fragments of root were treated with white wax, with white hard paraffin, and with lard, to all of which the red colour was yielded. My friend, Rev. H. E. Bishop, of Middleton Vicarage, near King's Lynn, has been successful in growing the true *Anchusa* (*Alkanna*) tinctoria in his rockwork garden. He has kindly supplied a specimen, from the root of which the accompanying specimen of lard has been coloured pink, as well as a disc of white wax. The living plant and its flower are also sent. The red colour of the root is very marked. It contains much larger quantities of the colouring matter, of course, than does the *Echium*."

Petunia Lord Courtenay.—This charming rosy pink coloured variety, which is in danger of being grown under diverse names this season, is of a very attractive appearance indeed, whether grown in the open border or in pots. Pink and rose-coloured Petunias are not unknown to gardeners. There was the Shrubland Rose of many years ago, deep pink, and Marquise de la Ferte, soft rose with pure white throat; followed later by Countess of Ellesmere. And now comes Lord Courtenay. The small-flowered rose-coloured pink Petunias are usually of dwarf and compact growth, at the same time very free blooming, and thus well adapted for cultivation in pots, and in this form they make excellent subjects for conservatory decoration. I find them freer of bloom when grown in pots than in the open border; but unsuitability of position may have had something to do with their comparative failure in the latter. *Petunia Lord Courtenay* promises to be one of the most interesting novelties of the year, and I have no hesitation in prophesying that it will prove a very useful plant.—R. D.

Trachelium coeruleum (Blue Throatwort).—It is gratifying to find this fine old greenhouse perennial being announced as a good plant for table and house decoration. Forty or so years ago it was a popular plant in gardens, valued on account of its easy growth and its characteristic of blooming freely; and it was thought to be worthy of cultivation as a specimen for exhibition. During the summer it bears a profusion of broad clusters of pale lavender-blue

blossoms; there are also a white variety, and one or two others. In the warmer parts of the country it may be grown as a hardy plant on rockwork in sheltered spots, but it is for general purposes a greenhouse perennial subshrub. One excellent use to which it can be put is as a vase plant. In some parts of the country working men send to local flower shows well-grown and bloomed plants of the *Trachelium*. A sandy loam of good heart suits it for pot culture. It can be propagated by means of cuttings taken in spring and struck in a gentle heat, and it can also be raised from seeds.—R. D.

Biarum or Ischarum eximium.

There are many singular plants among the Aroids, but there are also many among them of great beauty. Unfortunately, a number are possessed of odours far from agreeable, and some may well be said to have these so pronounced as to make them undesirable occupants of a garden. Some of them, however, are practically odourless, and it is only when they are in a room or glass house that they are unpleasant. Among the latter one would place the striking *Biarum* or *Ischarum eximium*, a species introduced from Western Cilicia in 1898, but only brought before the notice of growers within the last three or four years, since it was imported in some quantity through the medium of Mr. Siehe of Mersina, Turkey-in-Asia. It is a hardy plant, which is fortunate, as a specimen in a pot taken into the house soon found itself expelled in a somewhat unceremonious fashion. Yet it is of considerable beauty, and as a plant for the open garden it attracts much attention from those who appreciate singularity and beauty combined. It is at present in flower, and is very striking with its dark purple-brown spathe in the interior, quite velvet-like, and the conspicuous spadix of rather deeper hue. The outside of the spathe is pale green, spotted with brown, and the plant when in flower is about 6 inches high. The leaves, which are produced after the flowers, are of the familiar shape of many of the Aroids, and are of a pleasing green. But for its odour, *Biarum eximium* would be a peculiarly interesting, though not showy, house plant, but this defect is a sufficient bar to its use as such, and it ought to be relegated to the border or the rockery. It is being offered as *Ischarum eximium*, but I am following the authority of the "Index Kewensis" in calling it *Biarum eximium*, that great work referring the whole of the *Ischarum*s to the genus *Biarum*.—S. ARNOTT, *Carsehorn*.

Nerines in flower at Kew.—By the fourth Monday in October the flowers of some of the *Nerines* were past their best, but at Kew there was at that date a very interesting series still in bloom. The following sorts were particularly noticeable: *N. excellens*, carmine-pink, with a deeper coloured stripe down the centre of the crisped petals; *N. lucida*, large, light pink flowers, arranged in a very spreading umbel; *N. humilis coerulesa*, a dwarf free-flowering sort, whose pink blossoms become suffused with a bluish or leaden hue; *N. humilissplendens*, like the last, the narrow petals are very much crisped, but in this variety they are of a rich carmine-red, a very effective

PEAR LE LECTIER. (Slightly reduced.)

tint; *N. sarniensis major*, far and away the most brilliant of all at that time represented, the flowers being of an intense scarlet-vermilion tint, and when lit up by a ray of sunshine they glitter as if bedewed with jewels; *N. sarniensis*, rosy scarlet; *N. curvifolia major*, syn. *N. Fothergilli major*, bright scarlet; *N. amabilis*, bright pink, the petals most crisped of any; and *N. Novelty*, a very distinct form, whose colour may perhaps best be defined as salmon pink, with a deeper stripe down the centre of each petal. While some of the many *Nerines* now met with are original species, there are numerous garden forms in cultivation, for in days long gone by Messrs. Henderson of Maida Vale and St. John's Wood raised and distributed several, and we now annually look for an exhibit from Mr. Elwes of his delightful seedlings at one of the Royal Horticultural meetings about the middle of October.—T.

THE NEWER APPLES AND PEARS.

APPLES.

RIVAL.

AT the recent Royal Horticultural Society's show of hardy fruits at Westminster this new Apple was much admired. The raiser, Mr. Charles Ross, must have felt proud to see his new seedling in such a prominent position; and not only the raiser but Messrs. Cheal also, who sent out this new fruit, had splendid examples. Just at the moment I am unable to note the parentage, but it is one of the seedlings Mr. Ross thought most highly of, as he considered it would take a foremost position for its good flavour. The fruits are very pretty, rather conical, and bright in colour, and the tree is a great cropper even when small. It will be valuable for gardens of limited size, as when grown on the Paradise stock it soon fruits.

CHARLES ROSS.

This fruit was also staged in excellent condition. It was so fine this year, as represented at the show, that at first anyone might well be pardoned if they mistook it for Peasegood's Nonsuch, and I think in time the society would do well to make the same rules here as regards size, as in the case of the Blenheim Orange fruits that must pass

through a 3 inch ring. No fault whatever could be found with the large fruits, but I feel sure that the smaller ones are more valuable for dessert. I am sure both the raiser and distributor will not think I am complaining of the quality of this fine fruit. Certainly not, but of its value for dessert when of the size named. As this variety will doubtless be much grown in a few seasons, it may be advisable to make two classes.

ALLINGTON PIPPIN.

Messrs. Bunyard have reason to be proud of such a splendid fruit as this. It appears to do well in all parts of the kingdom, though the fruits from the northern counties at the recent fruit show lacked the size and colour of the southern ones. Everyone had a good word to give this variety as regards its cropping. It is now ten years old, and has had sufficient time to become known. It certainly does not fail to keep the position it obtained when it received a first-class certificate in 1894. The first and second prize dishes at the above exhibition came from Kent and Sussex respectively, and they were remarkable for their finish and colour, though it is only fair to add many others in the single dish class for this variety were well deserving an award. Few new Apples have proved more valuable in such a short time as Allington Pippin. In heavy soil the colour is splendid, and the trees grown on the Paradise stock are most prolific.

WERDER'S GOLDEN REINETTE.

This Apple was staged before the fruit committee of the Royal Horticultural Society on the 4th ult., and received an award of merit. At first one would think an Apple given an award on this occasion to be a new variety, but this is by no means the case. It is not, however, largely grown. This variety was well staged years ago at the great Apple conference held in the old gardens belonging to the society at Chiswick, and the late Mr. Barron was very fond of it. Strange to relate, it was just twenty-one years since this variety was noticed at the conference, and I do not remember seeing it since that date, but it should not be lost sight of. It is a fruit of excellent flavour, small, and has rather a large eye, the colour being pale yellow, with russet markings. At Chiswick this variety cropped well. The fruits were staged by Messrs. Veitch, and were grown in their Langley nursery. The flavour was first-rate. It is well that these small but highly-flavoured fruits should be thought of, and, though of more value in private gardens, I fear of late years small fruits have less chance than the large, showy ones, but for dessert mere size should not count.

KING'S ACRE BOUNTIFUL.

A beautiful cooking Apple from the King's Acre Nurseries, Hereford, a county next to Kent in the production of good hardy fruit. The new Bountiful will certainly become a favourite for its size, shape, and colour. The quality is first-rate; it is an early fruit. The skin is yellow and the fruit large, and not unlike Pott's Seedling, but more conical, with a brisk, pleasant flavour; it is a heavy cropper, and excellent for cooking. It will be interesting to test its keeping qualities, as though given an award early in October I should think

the fruits will be even better as regards quality some weeks later. Owing to its firm flesh and brisk flavour, it should be a good late autumn fruit.

HECTOR MACDONALD.

This Apple is the result of that excellent fruit grower's labours—Mr. Charles Ross of Newbury. I am not aware of the parentage of this new fruit; it is a cooking variety, large, and remarkably handsome, somewhat resembling Peasgood's Nonsuch in shape, but with a firmer flesh. The flavour is brisk; the fruits are covered with red on the sunny side, and Mr. Ross says it is a splendid cropper, so that it will be a valuable introduction.

PEARS.

MARGUERITE MARILLAT.

This recently-introduced Pear made a splendid display at the great fruit show held recently in the new hall. The fruits from Sir Marcus Samuels' gardens, Maidstone, were very beautiful, also those from Woburn Park (gardener, Mr. Basile). I noticed the same good quality was conspicuous in several of the other collections. At first sight any one would think this variety a very fine *Souvenir du Congrès*, but of a brighter golden hue. There can be no question, however, as to its value, as for the past two seasons our cordon trees have borne large crops. This Pear has now been grown long enough to test its value, and of course the chief point would be its flavour. It does not keep long, but it is very sweet, juicy, and a most valuable early autumn Pear. The tree is of upright growth, compact, and will succeed well on a west wall. Some may object to its size; but grown as a bush or pyramid it will be a valuable addition to the early autumn fruits.

CONFERENCE.

Those who saw the splendid fruit trees in pots which formed the centre of Messrs. Rivers' group at the recent great hardy fruit show of the Royal Horticultural Society will have noticed trees of the above Pear, the plants being grand specimens and laden with fruit. Conference is not of such good quality as *Doyenné du Comice*, but this Pear is unequalled in this respect. Such sorts that fruit like the new Conference are worth noting, as there are so many of the older ones that do not equal the

last named, either in crop or quality. The fruits are very distinct, and when the trees are on the Quince stock the flavour is very good, the fruits being melting and juicy, with a rich flavour if they are not gathered too early from the trees. They are large, pyriform in shape, and few Pears have such a distinct character; the skin is a very dark green, but the greater portion is covered with russet. The tree is remarkably hardy and prolific; indeed, in the latter respect it has few equals, as it so rarely fails to crop, even in bad years. It is one of the best Pears for pot culture, or what may be termed orchard house treatment, its season being early November. This fruit was a few seasons ago given a first-class certificate by the Royal Horticultural Society.

ST. LUKE.

For this valuable introduction we are indebted to Messrs. Rivers of Sawbridgeworth, and it is worth a note for its quality. St. Luke is an October Pear, and though as regards its season we then have some of the best Pears to select from, I may safely say that we have none too many of first-rate quality, and there is ample room for the newcomer, owing to its rich mellow flavour and melting flesh. This variety fruits well under pot culture, but as this mode of culture is not general it should be quite as good in other forms, and it will certainly make a good wall or cordon Pear. The raisers staged splendid baskets, and these, even when so many other good fruits were staged, could not fail to be noticed owing to their perfect shape and finish. This year's were very beautiful, and should make St. Luke a favourite variety for future planting.

S. T. WRIGHT.

This new fruit was named after the superintendent of the Royal Horticultural Society's gardens, and though the fruits staged were first-rate, I am not fond of one of the parents, *Beurré Bachelier*, as though the last named rarely fails to crop and the fruits are large and handsome, the quality is decidedly second-rate. I admit the tree is vigorous, and does well where others fail, and the new seedling may only inherit the good qualities of the parent. It certainly showed little of the flavour or appearance of the latter, having a russet skin, the fruits being medium sized and a

rich golden colour, in this respect more like the other parent, Williams' *Bon Chrétien*, so that doubtless, though later than the last named, it will be a valuable October fruit, and it is stated to be a splendid cropper; in this respect both the parents are excellent. This new Pear was raised by Messrs. Veitch, who of late years have certainly given fruit-lovers some excellent new fruits.

LE LECTIER.

A very fine large Pear that is ripe in December and January. The tree is of good habit. Either on the Quince or the Pear stock this variety does well. It is an abundant cropper, and the flavour of the fruit is excellent. Raised by Messrs. Veitch. It has received the Royal Horticultural Society's first-class certificate.

HACON'S INCOMPARABLE.

This Pear is of very distinct appearance, being, as the illustration shows, covered with russet. It is a large, handsome, and agreeably flavoured fruit, ripe in November and December. It grows best on the Quince stock, either as a cordon or a trained tree. When grafted on the Pear stock it will not thrive in all districts.

CHARLES ERNEST.

This is a large and handsome fruit of a yellowish colour, crimsoned on the sunny side, and marked with russet dots. It is of excellent flavour, and may be regarded as a valuable late variety. It is in season from October to December. Either as a pyramid, espalier, or cordon on the Quince stock it bears well. Messrs. James Veitch and Sons, Limited, Chelsea, raised this Pear, which received an award of merit from the Royal Horticultural Society in December, 1900. G. WYTHES.

PROPAGATION OF BUSH FRUITS.

CONSIDERING what an easy matter it is to propagate bush fruits, such as Gooseberries and Currants, from cuttings, one is surprised to see the specimens which encumber the ground in many gardens. Some of these have grown out of all bounds for the want of timely use of the knife, and others have old age and debility plainly written on every branch and twig. Exactly how long a Gooseberry or Currant bush will remain fruitful and profitable is largely a matter of treatment; but market men who grow them on commercial lines know that the heaviest crops and the finest fruits are obtained from young and vigorous specimens, and consequently a certain amount of propagation is continually going on in market establishments in order to raise stock to take the place of old specimens when they show signs of debility. Old and partially worn-out Gooseberry bushes are subject to various evils. Branches are apt to die off when laden with fruit, and the bushes are apt to be rendered leafless by attacks from that little pest the Gooseberry mite, which always plays more havoc with an old specimen than it does with one possessed of the vigour and vitality of youth.

For these and other reasons it is obvious that old worn-out bushes are not profitable, and in every garden a little space may be set aside as a nursery bed for the raising of young stock. The formation of cuttings is a simple matter, and as soon as the leaves have fallen in the autumn strong shoots of the current season's growth may be taken from Gooseberries, Red, White, and Black Currants for the above purpose. In the case of the three former fruits it is a distinct advantage to raise bushes having a clear stem above the ground, in the first place because the ground can be worked and kept clean up to the stem; secondly, because a bush of this type is easier to manage in the way of pruning; and, thirdly, because it produces the finest fruit. In order to secure the desired clean-stemmed bushes of Gooseberries and Red and White Currants, the cuttings should be made from 12 inches to 15 inches long, and after cutting just

PEAR HACON'S INCOMPARABLE. (Slightly reduced.)

below a joint all the buds should be removed with the exception of about four at the top. The non-removal of the lower buds is responsible for the springing up of sucker growths from the base, which are always a nuisance, because unless they are removed entirely they continue to grow as fast as they are cut back. The cuttings may be inserted in rows about 6 inches apart and to a depth of about 4 inches, treading the soil firmly to keep them in the ground.

In the case of Black Currant cuttings there is no need to remove the lower buds, because here a bush with a clean stem above the ground is not desired. On the other hand, the strongest young shoots on Black Currants, which produce the finest fruit, are sent up from the base of the bush in the same way as the best growths are obtained from a hybrid perpetual Rose. Indeed, the whole principle of pruning a Black Currant consists in thinning out old and useless wood with the object of encouraging strong shoots from the base. Care should be taken to protect the buds on the inserted cuttings from birds in the spring, and if no harm comes to them, the breaking into growth signifies that rooting has taken place. The young growths formed from the buds left on the cutting should be allowed to grow unchecked the first season, and in the autumn, or twelve months from the time of insertion, the little bushes may be lifted and transplanted. The following spring the four young shoots on each should be shortened to about half their original length, which will cause them to break strongly lower down, and thus the foundation of a good specimen is laid.

With reference to Black Currants, the now well-known bud mite is causing such havoc among this fruit that the greatest care should be exercised to propagate from none but clean stocks, as it is doubtless through the neglect of this precaution that the evil has spread to the present alarming degree. Whether anything will be done in the future to check the spread of this evil is an open question, but propagation from nothing but perfectly clean stocks is certainly the best preventive at present. In the way of varieties we have no more useful sorts amongst Gooseberries than Keep-sake, Whinham's Industry, and Crown Bob, though for fine flavour Early Sulphur and Greengage might be added. Raby Castle is a fine Red Currant, though Comet is larger, and White Grape is among the best of the whites. The old Baldwin and Lee's Prolific are two good Black Currants, and I would also recommend Boskoop Giant, which certainly has some mite-resisting capacities.

G. H. H.

OUTDOOR PEACH CULTURE

PROTECTION WHILE IN BLOOM.

THE subject of the extension of fruit growing as an industry in England has been much advocated during late years, both in the Press and on public platforms, and undoubtedly from statistics furnished and other evidence this advocacy is having its reward, if slowly, in the increased acreage devoted throughout the country to fruit culture and in the quality of the fruit seen at exhibitions and in the market, the latter the produce of younger trees. But this increased activity in the culture of fruit is confined chiefly to Apples and Plums, and in a less degree to Pears. With regard to the Peach out of doors the case, I am sorry to say, is the reverse, as there are fewer grown now than used to be the case twenty or thirty years ago. Why is this? It is not too much to say that in its season no fruit is more enjoyed than a luscious Peach or Nectarine, especially when grown out of doors on a sunny wall.

It is difficult to give a reason for this decadence in Peach culture, as this tree succeeds so well on south walls in all the warmer

parts of Britain. In the public mind I think Peach culture is more or less looked upon as a luxury, a luxury only to be indulged in by the well-to-do. This is a great fallacy. It is as easy to grow as the Plum, provided the soil and climate are suitable and a south wall available. It is very seldom indeed that the Peach fails to produce a good crop, and it is therefore remunerative to grow. Recently I had the pleasure of visiting the gardens at Hatfield House.

Mr. Norman drew attention to a Peach wall that claimed my genuine admiration. The trees were perfect specimens of good culture. I have never seen better; every inch of the wall appeared to be covered with healthy bearing wood and clean foliage. Mr. Norman assured me that for the past ten years the trees had only once failed to produce good crops. This can be said of very few other fruits. Moreover, during the whole of that time the trees have received no protection while in bloom, not even the conventional herring-net. This is a point, in my opinion, that requires strongly emphasising.

It is a belief, almost a strong conviction, with many gardeners that to grow the Peach successfully it is essential that an expensive coping of wood, or glass with blinds and rollers, be fixed to the wall, entailing much cost and endless labour in rolling up and down night and morning afterwards. That this is unnecessary has been proved at Hatfield, as stated above, and I may say that my own experience, especially at Frogmore, goes entirely to support Mr. Norman's practice. There we had great length of wall devoted to Peach culture out of doors.

Three parts of the walls were furnished with portable glass copings, which, with the blinds suspended from them, were fixed in position every spring before the trees were in bloom. The other portions of the walls were left quite unprotected for the ten years they were under my charge, and during that time I could never detect that fuller or better crops resulted from the protected trees than from the unprotected. This fact, I think, cannot be too widely known, as it is generally believed among growers that these expensive adjuncts are necessary to the successful growth of the Peach out of doors. This belief in a great measure, in my opinion, is responsible for the decadence and want of interest taken in the Peach as a hardy fruit tree.

OWEN THOMAS.

METFORD'S LEMON.

(CITRUS MEDICA VAR. LEMONUM.)

IN the Mexican wing of the Temperate house at Kew this very remarkable variety of Lemon has fruited. The tree is about 12 feet high, and the fruits were 8 inches long and 6 inches wide, the leaves being 8 inches by 4 inches. I recorded the history of this Lemon in your contemporary, the *Gardeners' Chronicle*, as follows:—"In January, 1896, Miss Laura Metford Badcock of Fons George, Taunton, forwarded to Kew a large Lemon fruit which had been grown in the garden of Mrs. Tucker at Leigh Court, Angers Leigh, Wellington, Somerset. Miss Badcock wrote:—"The history

METFORD'S LEMON IN THE MEXICAN HOUSE AT KEW.

of the big Lemon is this: The original plant was grown from seed by my great aunt, Miss Metford, at Hook House, Taunton, in the very early years of this century, and was kept there till 1868, when the place was sold at my grandfather's death, and the plant given to a friend, who let it die. The present and only plant was grown from a cutting of that tree given by my grandfather, Dr. Metford, to Mrs. Tucker, and now owned by Miss Tucker, who sometimes gives us a Lemon from it. I will ask her to forward a few cuttings from the tree to you. My people were so proud of this tree that I should be glad

if you could name it Metford's Lemon. Shortly afterwards, Miss Tucker, when forwarding two cuttings from her tree, wrote:—"It had so many fruits in the past two years that it has not thrown much young wood. For want of space it had to be pruned."

This is undoubtedly a form of the true Lemon, *Citrus medica* var. *limonum*, but I have not been able to find any form exactly answering to it among the many described and figured in botanical works. The nearest is one figured in Dr. Bonavia's illustrated work on the Citrus family in India, under the name of "Kumaon" or "Gulgul" Lemon, which he calls the "Elephant" variety of the Lemon group. That, however, differs from Metford's Lemon in its smaller fruits ($1\frac{1}{2}$ inches in girth), the roughness and wartiness of the rind, the "bronzy reddish-brown" colour of the flowers, and the wingless leaf-stalks.

When recommending the better sorts of Oranges and Lemons for cultivation in India, Dr. Bonavia says:—"Lahore should give attention to the large sour and juicy Lemon known in the Punjab as 'Gulgul.'" In this connexion we may mention that Mr. George Monro of Covent Garden, to whom the fruit sent to Kew by Miss Badcock was forwarded for his opinion as to its usefulness commercially, considered it much too large to find a ready market. W. W.

THE ROSE GARDEN.

SEASONABLE NOTES.

BY the time these lines are in print the Rose nurserymen will be busy despatching their orders. And the question arises whether our beds and borders are ready for the reception of the plants. Every good grower is fully alive to the necessity of the most careful

PREPARATION OF THE BEDS AND BORDERS.

Few of us can alter our soil. The best must be made of what we have. True, it is possible with many individuals to set apart a portion of a meadow for a Rose garden. And how successful this plan has been many growers have now cause to rejoice. We hear a great deal about the rich loam, but how frequently we find the best Roses come from soils anything but good. Deep tillage is of the utmost importance to successful Rose culture. Let the soil be well trenched to a depth of 3 feet if possible. One of our most successful amateur exhibitors assures me he always trenches 3 feet deep. Do not stint the farmyard manure. How baneful is the practice of applying fresh manure to the soil. We impose a task upon the soil which should have been accomplished in the manure heap, so that I would urge the use of manure that has been well turned during the summer. In addition to this add bone-meal or $\frac{1}{2}$ -inch bones to the soil as trenching proceeds.

New beds or borders should be raised fully 9 inches above the surrounding surface. If the soil is heavy an application of lime rubbish will be very helpful, and also if drainage is bad 5 inches or 6 inches of broken bricks placed in the bottom of beds, with turf, grassy side down, on top of them will be very useful, especially in the case of beds intended for the true Tea Roses.

WHEN TO PLANT.

Undoubtedly October and November are the best months for this operation, but rather than plant when land is wet the Roses had better be heeled in until the land is in a fit state. The soil should be neither too dry nor too wet. When the soil is very wet and it is trodden firmly about the roots it simply settles into a hard brick-like substance in which nothing can thrive. But if in a nice friable state, something like soil used for potting plants, then we may look for good results from our planting. I would strongly urge buyers to procure their plants

early, and if they cannot plant when the package arrives the plants may be securely heeled in under a north wall or hedge, and they can so remain until spring if necessary. In very cold and wet districts spring planting is by far the best, but as it is necessary to secure strong plants they should be obtained in autumn. The question arises what to plant. Without a doubt Hybrid Teas will be in the majority, but a careful selection of the best Hybrid Perpetuals should also be planted, as they supply the brilliant colours, the delicious fragrance, and the glorious form we admire so much. Are standards as good as bushes? I am often asked, and I reply that some sorts do equally as well either way. It is the free, bold type of Caroline Testout, Frau Karl Druschki, &c., that makes the best heads on standards, not forgetting, of course, several of the Teas. Many individuals think it is difficult to grow those lovely Roses Cleopatra and Comtesse de Nadaillac, but try them on vigorous standards or half standards and see. This latter Rose, instead of being the most difficult, is one of the easiest, providing a well-drained soil and warm aspect be provided for it. The

DECORATIVE ROSES

are fast usurping the position of the bedding plants formerly so popular, and how can we miss the opportunity to extend their culture? Just now (October 20) beds of Grüss an Teplitz, Corallina, G. Nabonnand, Enchantress, Caroline Testout, &c., are more beautiful than anything else in the garden, and have been for some time. But perhaps the Rose that pleases most is the one that gives abundantly a flower of beautiful colouring and form, such as is exemplified in Mme. Abel Chatenay and Antoine Rivoire. It will be a long time before such Roses as these are superseded. I would make a small plea for old-fashioned Roses, for after all it is in the sweet June time that Roses seem so dear to us, and these old Roses blossom then in profusion. Pillar Roses should abound in every suitable position. I have seen them used with good effect, interspersed over large beds of bushes. Such sorts as Frau Karl Druschki, Gloire des Rosomanes, Anna Alexeiff, Gloire Lyonnaise, &c., are grand for this purpose.

Rambler Roses, creeping Roses, fountain Roses, and weeping Roses must all be found in the large rosery. How far they should appear in the small Rose garden must be a matter of individual taste. Roses of short season, however splendid their display, can never maintain their popularity against those of more perpetual flowering qualities. There are many who would rather plant Grüss an Teplitz or climbing Cramoisi Supérieur than the showy Crimson Rambler, because in the former instances there is a brilliant effect when most needed in autumn.

TRIAL BORDERS

of untried varieties I would strongly advise, especially to those who plant to a colour scheme. So many Roses are disappointing when regarded from their decorative effect in the garden. By planting one or more of quite a number of sorts far better results would be obtainable from the experience such borders would provide.

RENOVATING OLD ROSE GARDENS.

Making beds and borders can be safely taken in hand now. I am convinced we do not transplant our Roses frequently enough. Simply lifting them, turning over their roots, and returning the plants to new beds, or the same renovated, would put new life into many, and the summer display would be far more satisfactory. A shovelful or two of good compost placed about the roots will work wonders in creating a vigorous growth.

OLD STANDARDS, PILLAR, AND RAMBLER ROSES that are too large to move can be very much improved by removing the worn-out soil around and partly beneath the roots, taking care to disturb the latter as little as possible. Replace with new soil, or part new and part of the old with well-decomposed manure incorporated. The result may not be apparent until the latter part of next year, but from this time onwards the plants will take on a new lease of life, that is, of course, if they are not too far gone before the work is taken in hand.

FORCING ROSES

should now be overhauled and placed under cover in pits or a cold house. Some of the plants may be pruned and started at once, but the main supply will be pruned about Christmas. The time to allow from the pruning to the blossoming would be about twelve weeks. There is scarcely a Rose in cultivation but that has a charm about it when seen growing under glass in the dull months of the year, but as a rule the varieties that possess quality of blossom are preferred for forcing, and also those that bear their blossoms erect. Drainage is so important an item in the cultivation of pot Roses that no excuse must be found to prevent a thorough overhauling of the plants. Some plants may also require top-dressing. P.

CHRYSANTHEMUMS.

THE COMING SEASON.

JUDGING from what I have seen, and the reports that reach me from many sources, the Chrysanthemum season of 1904 should prove to be one of the best on record. The growing season was all one could wish for, and where the plants have been properly treated there is every indication of high class flowers, the wood and foliage being well matured, and, fortunately, the dreaded rust is much less in evidence than it has been for some years. The Japanese section has been very largely added to and much improved from many sources. Since the English raisers have taken the matter in hand they have done much to uphold the high standard of this beautiful and varied class. The great variety of colours and the many diverse forms will, I am convinced, tend to make these popular and interesting for many years to come. Whites, yellows, and lilacs undoubtedly prevail, and, strange to relate, up to the present time no one has been able to succeed in giving us a good crimson to take the place of that once famous variety named after that noted grower E. Molyneux, a variety which has probably held its own longer than any other.

IMPROVED WAYS OF EXHIBITING.

It is gratifying to note that the old and foolish method of exhibiting these in cups and tubes on boards is fast dying out, and the system of staging the flowers on long stems in vases is now becoming popular at most exhibitions. Credit must be given to our Scotch friends for taking this forward step, and even at the present day nowhere that I know is the same encouragement given as at the great Edinburgh show, and I venture to predict that before long this system will become quite universal in setting up blooms of all sections. Well grown incurved flowers look equally well, and, indeed, the same may be said of the charming Pompons, singles, and, in fact, the whole of the decorative varieties.

By the time these lines are in print the friendly rivalry will have commenced, and those who have spent many months in paying close attention, and watching almost every petal as it unfolds, will not be sorry that the anxious moments are passed, and I trust those who have not met with that share of success which they had hoped for will not be disappointed or disheartened, but will return to the field of labour with an incentive to do better in the future, especially those who are young in the profession and have made up their minds to make a name for themselves. Success can only be achieved by determination, and learning to take defeat in a manly way. The chief points in relation to

EXHIBITION CHRYSANTHEMUM FLOWERS,

which comprise Japanese, incurved, large Anemones, and reflexed, are size, colour, and freshness; of course, evenness throughout, either on boards or in vases, is also most essential, and when three or five blooms, as the case may be, are required, these should be as much alike as it is possible to get them. Extreme dressing should not be indulged in, as, in my opinion, the flowers

should be shown as naturally as possible, thus revealing their general character. At the same time, any decayed or bad petals should be carefully removed, and hard centres, which may interfere with the proper development of the flowers, should be taken out when the bloom is about half expanded. Any which are not likely to keep fresh on the plant for any given date may safely be cut, placed in water, and kept in a dry, dark room, where they will remain in good condition, if the water is changed frequently, for a week or ten days. Shade the general batch of plants during bright sunshine, and especially after dark, dull, foggy weather. Ventilate freely when the weather is clear, but great care should be exercised when wet and dull. Extreme fire-heat should certainly be avoided, but the pipes should be warmed just sufficient to maintain a dry, buoyant atmosphere. Do not hesitate to fumigate the plants with X.L. All when any sign of green fly is in evidence, as good flowers can never be expected when they become infested with this.

SPECIMEN PLANTS

should now be finally tied, and so arrange the plants that the whole of the flowers may draw to the front. Liberal supplies of manure water should be given these, as it is at this period that the greatest strain is felt. Late plants, which are still outside, may remain there for another fortnight, providing they are well protected during frosty weather. Thoroughly stake and tie the plants, and give manure every other watering; dust with flowers of sulphur, and moderately thin out the buds sufficiently to allow each one to develop properly. These will be found to be extremely useful during midwinter when other flowers are none too plentiful.

E. BECKETT.

Aldenham House Gardens, Elstree.

GATHERING AND RIPENING LATE PEARS.

GOOD Pears are often spoiled by being gathered too soon and neglecting to help them with a little heat to bring up their flavour later on when their season for use draws near. This more especially refers to late Pears, which are supposed to be in season from Christmas onwards. During October and November there are generally in most gardens where Pears are grown more than can be consumed, but when the Christmas festivities are over there is not infrequently a scarcity of really good fruit. Late Pears should be left on the trees as late as they are capable of holding. Early gathering means early ripening, if the fruit do not shrivel; in the latter case of course they are useless. *Easter Beurré* especially must be left on the tree as long as possible, as it has a habit of ripening before its proper season, though soil and situation have something to do with this. All late Pears should be kept in a dry, cool, dark room till about a fortnight before they are required for use, and should then be placed in a temperature of 60° to ripen as required. If not the best Christmas Pear *Glou Morceau* is certainly one of the best, and it rarely fails to bear on a wall. This should make a profitable sort to plant against the gable end of a lofty building in a good aspect, with the roots kept out of the cold subsoil, especially where this is clay, though I have found a subsoil of sand

as injurious to Pear trees, when the roots penetrate it, as clay. An excellent old winter Pear will be found in *Winter Nelis*, valuable not only for its excellent flavour, but also for its long season. If kept in the dark and taken into a temperature of 60° a few at a time as required its season will last for pretty well three months. *Knight's Monarch* is another old Pear that is excellent in point of flavour, and will keep in condition for several months. This is not much grown now, at least I have not often met with it of late years, though I have pleasant reminiscences of an old tree I knew many years ago in *Worcestershire*. It never carries a very heavy crop, *i.e.*, it never injures itself by overbearing, as when heavily laden it will generally cast some of its fruit. I have often seen the ground beneath the old tree above referred to strewn with immature fruit.

ORIGINAL TREE OF APPLE MRS. PHILLIMORE.

(Raised by Mr. Rows.)

Doubtless a mulch of manure would check this habit of parting with its crop. *Olivier des Serres* is an excellent late Pear, and deserves a place in every garden, its season being from February to March. *Ne Plus Meuris* generally bears freely, both on espaliers and also on walls. The finest and best samples come from a good aspect on the wall, preferably south or south-east. Perhaps one of the most uncertain late Pears is *Beurré Rance*. I have had it delicious, and I have had it hardly so good as a Turnip. It requires a sunny and airy position. I have had this Pear good from espaliers occasionally, but the best samples I ever saw were grown on the gable end of a large thatched barn, the thatch projecting sufficiently to protect the blossoms in spring. *Bergamotte*

Esperen sometimes bears freely, especially on the Quince, but though an excellent flavoured Pear it has not yet established its reputation as a free-bearing kind. *Doyenné du Comice* with me comes in before Christmas, and can therefore hardly be called a late Pear, but it is, without exception, one of the best mid-season sorts, and will probably be more planted than it has hitherto been, as it grows freely in all aspects and situations, and succeeds well on the Quince. *Josephine de Malines* has received a high character in the past, but it does not do well everywhere. Some years ago I tried it on the Quince, but it was not a complete success. The tree did not grow well and the Pears were gritty. This might have been due to the soil of the locality, as certain Pears are gritty on particular soils. My impression is, now that building materials are reasonable in price, it

would pay to put up roomy houses for the best late Pears, such as some of those I have named above, and others not so well known. I have never tasted an early Pear grown under glass worth eating, but most of the late Pears are improved in every respect by being grown under a glass roof. There would be no occasion to use artificial heat in a large house, as if well ventilated during winter the trees would not be much earlier in blossom under glass than against a wall. Strawberries in pots might be worked in the intervals between the Pear trees. I have grown Pears in pots, but in a good-sized house (and I should not care for a house for this work less than 30 feet wide) I would rather plant the trees out in the border and train them to trellises running along the houses. This arrangement would, I think, provide the largest amount of training space. Some day I have no doubt the cultivation of late Pears under glass will receive attention. E.

NOTABLE GARDENS.

WELFORD PARK, NEWBURY.

WHEN you get away from the beaten track in any county it is easy to find many beautiful spots, and in Berkshire it is, perhaps, easier than usual. At least, one is apt to think so when passing through the beautiful Lambourne Valley that stretches from Newbury towards Lambourne and the Vale of the White Horse. Leaving the quiet town of Newbury, the road passes along one side of the valley, giving one a glorious view over rolling downs, dotted here and there with hamlets, each with its church tower or steeple nestling now in a lovely leaf-setting of green and gold and red. One gets glimpses here and there of the rippling stream in the hollow, known only as Lambourne trout stream if the knowledge of a local guide is to be trusted. And thus for some seven miles the road lies through undulating downland, up hill and down hill, with something of interest on every side.

Welford Park lies hidden amid giant trees, and you are close to the house before even a glimpse is obtained of it. Most remarkable among these giant trees perhaps are those

planted by Mr. Ross, who has been head gardener here for forty-four years. With pardonable pride he points out huge specimens of Douglas Fir 60 feet high that he planted some forty years ago. More remarkable still, perhaps, are two trees of *Abies grandis*, which Mr. Ross planted in 1878; now they are 70 feet high. Few men live long enough to see such results from their labours. Mr. Ross, who is eighty years old, has lived to see his tiny seedlings develop into giant trees; the woods contain many 60-feet-high Douglas Firs that he planted about 1870.

There is a curious history attached to the tree of *Abies homolepis* shown in one of the illustrations. The date of the introduction of this tree from Japan is given as 1870, but when Mr. Ross came to Welford Park in 1860 he found a tiny plant of it growing in a pot. He planted this out in the grounds, and now it is about 48 feet high. Last year its measurements were: Height, 46 feet; diameter of spread of branches, 26 feet; circumference of trunk 1 foot above ground, 5 feet 2 inches. In striking contrast to the rapid growth made by *Abies grandis*, there is a specimen of the Himalayan Weeping Spruce (*Picea Morinda*), which, although planted some years before them, is now only 15 feet high. Thus, so far as their behaviour at Welford Park is concerned, *Abies grandis* and *Picea Morinda* may be said to be the quickest and the slowest growing among the Firs. Other notable trees are *Picea Pin-sapo*, 60 feet high, planted in 1840, and *P. Laricio*, planted in 1834, now over 60 feet high.

Mr. Ross has a record as a fruit grower and a raiser of new varieties such as few gardeners can show. He has obtained no less than three first-class certificates and eight awards of merit for new Apples, all raised at Welford by cross-fertilisation or by the selection of seedlings. Welford Park Nonsuch was the first to obtain a certificate; it is a seedling from Golden Harvey (The Brandy Apple). Armored, a small late dessert Apple, also obtained a similar award some years ago. Charles Ross,

of which we give an illustration, received an award of merit and a first-class certificate in the same year. This Apple is the result of a cross between Peasgood's Nonsuch and Cox's Orange Pippin. Other varieties for which Mr. Ross has obtained an award of merit are Bella, Paroquet, Opal, and Atalanta (all fairly old sorts), while among those of recent introduction are Mrs. Phillimore (Lord Burleigh x Mr. Gladstone), The Honblon, and The Rival (both obtained by crossing Peasgood's Nonsuch with Cox's Orange Pippin). The variety Hector Mac-

ABIES HOMOLEPIS AT WELFORD PARK.

(This is the oldest tree in the country, and is about 48 feet high.)

APPLE RIVAL. (Natural size. Raised by Mr. Charles Ross.)

donald (Mr. Ross does not know the parentage) received an award of merit at the Royal Horticultural Society's fruit show on the 4th ult. Another new one, called Redwing, a large, richly-coloured fruit, will be exhibited shortly. It may not be generally known that Mr. Ross raised Pear General Wauchope. For some time past he has been trying to cross-fertilise Cornish Gilliflower with Cox's Orange Pippin, but so far his efforts to obtain seeds have been fruitless. With such a record as a raiser of new Apples Mr. Ross, we feel sure, will finally succeed in uniting the good qualities of these two famous sorts.

T.

THE FLOWER GARDEN.

PROPAGATING TROPEOLUMS BY CUTTINGS.

VARIETIES of *Nasturtium* which are derived from *Tropeolum majus*, *lobbianum*, and their hybrids are usually propagated by seeds, which reproduce almost exactly the characteristics of the variety. But there are exceptions, especially among the double-flowered and variegated leaved sorts, which are both sterile; and likewise for some others, such as *C. chameleon*, *Mme. Günter*, and its varieties, whose characteristics are so distinct that they must be preserved by taking cuttings. This process of increase can be applied to any interesting form it is desired to perpetuate, when by seeds its characteristics would not be reproduced. Striking the cuttings—a very easy matter—is done from July to September either in the open air or under glass. The cuttings may be placed at once in the garden or in small pots; in each pot four or five cuttings may be placed. They should be chosen from the lateral shoots, and cut to a length of 7 centimetres or 8 centimetres from a node. After the cuttings have struck—which they will do quickly and easily—they should be potted in small pots either singly or two or three together, and then left in the open air until October. Towards the end of this month they should be placed in an

unheated greenhouse, receive very little water, and be placed as near the glass as possible. The double-flowered and variegated leaved varieties trained over a framework when kept in the greenhouse form plants of much beauty. The varieties destined for the open garden are potted, placed on a hot-bed, and finally put in their places in the open air in May.—JULES RUDOLPH, in *Le Journal de la Société Nationale d'Horticulture*.

NEW CALO-CHORTI.

THIS genus of exquisite Californian bulbous plants has been enriched by the addition of two new species of real garden worth.

C. Goldyi (Watkins) is considered by some to be a

PEAR CHARLES ERNEST. (Slightly reduced.)

hybrid between *C. Benthani* and *C. amabilis*. It is a very interesting little plant, as pretty in its way as any of its brethren. The flowers are straw yellow, 1 inch across, erect, and covered on the inner surfaces with long, silky, sulphur-tinted hairs. A few crimson-tinted shorter ones occur low down in the cup. The petals are rounded and very hooded. Its bulbs are large, and they throw up several stems, freely branched, and bearing from fifteen to twenty flowers on each plant. The leaves are narrowly lanceolate, varying in length, and they do not differ materially from the majority of their tribe.

C. pulchellus vera (Douglas) is a fine strong-growing plant, better in the garden than the remainder of the *Cyclobothra* group of *Calochortus*. It received an award of merit from the Royal Horticultural Society when shown by Messrs. Wallace and Co. of Colchester some months ago. It has very erect branching stems, above 1 foot high, bearing upwards of a dozen yellow flowers, the petals of which are markedly hooded and fringed with short, stiff hairs on the margins. They average $1\frac{1}{2}$ inches in diameter, and are always pendent. This plant is the original *C. pulchellus*. It was not introduced to general cultivation from the first, and the discovery of a plant similarly shaped but much smaller, now known as

C. amabilis (Purdy), led collectors to suppose it was Douglas's plant, and it has been widely distributed as *C. pulchellus*. It rarely exceeds 6 inches in height, and produces branched nodding stems bearing globular yellow flowers half the size of those of the true *C. pulchellus*, but its yellow

colouring is brighter and richer. *C. pulchellus* is strong enough for border cultivation, whereas the spurious *C. pulchellus* is better adapted for a rock garden slope. Both plants require a slightly shaded position during summer and a light soil, whilst their winter resting season should be rather dry.

A complete and exhaustive monograph of the *Calochortus* was published in THE GARDEN, December 21, 1901, and subsequent numbers, and may be referred to for further information respecting these charming little bulbous plants.

GEO. B. MALLETT.

WILD GARDENING IN SPRING.

(Continued from page 289.)

ANOTHER experiment I made was to take the turf up and trench a space some 18 inches deep. This I planted with bulbs in the loose soil. They certainly started well, but just before blooming appeared to be drawn down into the ground and developed ill-formed blooms and yellow foliage. I supposed it was the roots growing down and seeking for moisture that brought them into this undesirable condition.

Alfred Austin tells us in his pretty book on his wild garden at Swinford Old Manor, that "Nature is continually sending even its oldest scholars to the bottom of the class for some stupid blunder, just in order that they may by patience and perseverance work their way to the top again."

Being at the bottom of the class, I tried again, and on the second occasion dug the hole 6 inches deep only, and planted the bulbs on the firm bottom. This, I am pleased to say, answered much better, but nothing, I find, is saved by this system in regard to time and trouble, as you have first to take off the turf and then replace it.

Here I should like to give a word of advice about the advisability of selecting

GOOD SOUND BULBS.

If it is important to have good strong bulbs for the borders, how necessary it must be that the best should be chosen to force their way through the carpet of turf.

I find that when planting Primroses and Polyanthus Primroses, &c., in grass, it is very important first to cultivate them in a border, and only the strongest roots should be used for this purpose. Move them into the grass in early spring when they begin to show bloom. With a little care in planting they will soon look natural and at home. When they have done blooming I dig up and divide the best strains, and bring them on for the next year in a cool shady border. If you leave them in the grass they get mown down, smothered, and become poor and weak the next season.

Do not plant the ordinary small flowering Polyanthus. The colours are too undecided, and in the grass have a washed-out and rusty appearance. Yellow, orange, and pink are best. The brighter and larger the flowers the better.

You need not be too particular about a few strong weeds growing among the flowers. I consider that a piece of sheep's Parsley, a Dock, or a

APPLE CHARLES ROSS. (Slightly reduced.)

Thistle here and there, gives the show a more natural appearance, and is rather an agreeable addition than otherwise; and here I would just like to say a good word for your old enemy the Dandelion. It has not many friends among gardeners, I know. Now I have a portion of my orchard that is simply full of them, and there I plant a good few late scarlet and white Tulips. You would be surprised to see what a pretty show they make on a sunny May morning growing in company. One of the brightest things I have all the year round is this display, but I must confess that I cannot inspire my gardener with much

should, of course, not forget the blue and white Bluebells" which I previously referred to.

The greater portion of the meadow I would plant thickly with tall-growing early and late Daffodils and Tulips, with some Hyacinths, also large roots of the Polyanthus Primrose. I should not consider how many colours were mixed together, for it is a curious fact that however colours may clash in the borders in grass gardening Nature seems to have a way of agreeably adjusting them. Nothing seems to jar or be out of place.

In the moist bottoms I should introduce such things as the marsh Marigold and many other

seem to like, and the combination has in a very short time a charming effect. I had some Roses planted in this way some years ago which have mounted to a height of 15 feet to 20 feet.

My experience is that if you wish to be successful with climbing Roses you must let them grow freely and pretty much as they like, using the pruning knife but very little. Train them carefully, and be sure and give them a plentiful supply of farmyard manure water during the spring and summer months. In

ROSE THALIA ON OLD APPLE TREE.

enthusiasm for this class of gardening, especially when the seeds, later on, are being blown about by the wind.

My ideal spring garden is an undulating meadow running towards the house, fringed with copses of thin undergrowth. In the meadow I should like to have some old spring-flowering trees, such as Crabs, Apples, and Cherry trees. Through the meadow I would have narrow grass walks, leading, as it were, everywhere and yet nowhere definitely. In the short turf near the edges of the grass paths I would cultivate little colonies of Grape Hyacinth, Chionodoxa, Scilla sibirica, dwarf Daffodils, Hyacinths, and Tulips. In suitable spots, where the grass does not grow so rank, I would have the blue Apennine Anemone, also our native white one, Snowdrops, Winter Aconites, Crocuses, Cowslips, all sorts of Primroses and Violets, Forget-me-not, and red and white Daisies. I

plants of a moist-loving nature.—Paper read by Mr. A. TROWER at a meeting of the Redhill, Reigate, and District Gardeners' Association, September 27.

ROSES OVER FRUIT TREES.

SHOULD there be an old orchard with ancient non-bearing trees, it is a good plan, instead of doing away with them altogether, to use the old trunks as supports for climbing Roses. The boughs should be shortened and the Roses allowed to climb up and fall over the sprays in as natural a way as possible. There is something about old Apple trees that Roses

giving them manure water take pains and make certain that it reaches the roots. I find a good plan is first to carefully remove the surface soil round all the trees, making a hollow holding about 2 gallons. If the ground is very dry I go all round and give them clear water first, then go back to the first tree and give them the manure, and when I have finished with that some more clear water. The same treatment applies to many of the H.P. Roses if you want a really charming and showy Rose garden, and an abundance of bloom all the summer and autumn. It is a great mistake to prune closely. I have dwarf bush H.P. Roses that are quite twelve years old; they are a mass of blossom every year. I prune them to bushes 3 feet to 4 feet high. New growth every year

is only a matter of feeding during the spring and summer. The free growth system, too, has another great advantage—you not only get many more Roses, but they are seen in the distance, and are not hidden by shrubs and other plants. E. T.

THE ROCK GARDEN.

SAXIFRAGA FORTUNEL.

THERE are not many flowers in bloom in the rock garden during October. Here and there patches of *Colehiscums* make bright splashes of colour, pushing up suddenly through tufts of mossy Saxifrage or other carpeting

plants, but save for some clumps of *Lobelia cardinalis* Queen Victoria, numerous late Phloxes, amongst which Marquis de St. Paul, a lovely white variety with brilliant salmon-rose eye, is a great favourite, *Heleniums*, and a few Michaelmas Daisies, planted amongst the neighbouring and sheltering shrubs, this part of the garden would be rather unattractive. On the north side of the rock garden, in a shady and sheltered nook, a little group of Fortune's Saxifrage is in bloom. What a dainty and lovely flower this is! The exquisite panicles of pure white blossom seem so delicate, and the half-transparent light green stems so fragile, that you would think they must break off with every gust of wind. It is essentially a connoisseur's flower. By this I mean that it is one of those good things which a true flower lover would never pass by without wishing to examine closely, but which an ordinary person might call "pretty," and not give it another thought afterwards. It is certainly true that this plant is very much neglected in many gardens, chiefly because it is supposed to be tender. In Vol. LVI. of *THE GARDEN*, page 383, under the heading of "Stove Plants," appears the following note in reference to this plant:—

"In the outdoor garden this autumn-flowering species is of but little value by reason of its tender nature. In the greenhouse, however, the plant is worth growing in pots, and with liberal treatment flowers with considerable freedom. It is only rarely, however, that sufficient interest is taken in these out-of-the-way kinds to do them justice. All the same, a well-grown plant is very pretty at the present time."

There is, however, no doubt as to its perfect hardiness, but owing to its late period of flowering, usually October, a sharp frost may cut it down before the blossoms have had time to expand. Yet how easy it is to give it protection—a light hand-frame placed over the plants will allow them to expand their flowers without hindrance. To those amateurs, and I know that there are many, who object to having hand-frames, bell-glasses, and other such things in their rock gardens, I would say grow this plant in a cold frame. I have never attempted to grow it in heat, so will not venture to

express an opinion as to whether it is to be recommended. But as it can be grown to perfection both out in the open and also in a cold frame, I cannot see the necessity for doing so. The panicles of flowers are usually 8 inches to 12 inches in height, and the petals are notched in a most peculiar manner, and are of uneven length. The bottom petal is very long, the two adjoining it are about half the size, while the two upper petals are still smaller. The anthers are of a bright golden colour. It is an exquisite flower for cutting, lasting well in water for many days. To enjoy it thoroughly place a few stems by themselves in a plain glass, then their true beauty will be more appreciated than if they were mixed up with other flowers. I never like to see Maidenhair Fern used with hardy flowers, but in this case a few fronds arranged

introduced as far back as 1863, and takes its name from the celebrated collector, Fortune, who discovered it in China. To those who do not mind the slight trouble of affording it a little protection just before and during its period of blooming it is a plant to be recommended. We have none too many good outdoor flowers in the late autumn days, and this plant possesses a quiet beauty and distinctiveness which alone make it well worth growing. Even in these days, when gardening has become more popular and the use of hardy plants is more fully understood than ever before, the complaint is still made that there is too much sameness in gardens. To herbaceous borders, this complaint is especially applicable, because, although originally planted with the best plants, the

coarser and more aggressive members of the border have been allowed to grow at will, the result being that the smaller and choicer plants have disappeared. Fortune's Saxifrage will not submit to being overshadowed and starved by coarse herbaceous plants. It is best grown as I remember to have seen it in Bath Botanic Garden, where Mr. Milburn had grouped it in a shady part of the upper bog garden.

ARTHUR R. GOODWIN.

The Elms, Kidderminster.

ROSE PAUL'S SINGLE WHITE ON OLD PEAR TREE.

with it will help to show it to advantage. It is a most floriferous plant, and even the smallest example will generally bloom. The whole plant is of rather a succulent nature, and the deep green kidney-shaped leaves, as also the leaf stalks, are covered with whitish hairs. The leaves, which are very handsome, are lobed and toothed, and the beauty of the plant is enhanced by the bases of the leaf stalks, which are bright red in colour, and this extends part of the way up the stalks. As for culture it wants none. I grow it in a mixture of peat and loam, but it does well in either, and only demands a moist and shady position and protection from drought. It is easily increased by division in spring, and a stock of plants may be soon worked up. According to "Nicholson's Dictionary" it was

NOTES ON HARDY PLANTS.

CYCLAMEN CILICICUM.

HARDY Cyclamens are so beautiful, small though they are compared with the magnificent varieties of *C. persicum*, that they hardly ever fail to attract those who visit gardens where they are cultivated. There is a peculiar charm about those which come in autumn, especially when it is drawing to a close and winter is near, as even when the flowers are over we generally have their prettily marked leaves all through the winter. The little *C. cilicicum*, now more plentiful than it was a short time ago, deserves a few lines at the present time, for a little flower which comes in bloom about mid-October or so and continues for a little while is welcome. This species has of late, through the medium of Mr. Siehe of Mersina and a few others, been imported in considerable numbers, and I have at present in bloom in my garden a little clump of *C.*

cilicicum which is very delightful, with its little flowers, varying in colour from white to pale rose, each with a purple spot at the base. The leaves are small, nearly round, and with untoothed edges. They are produced with the flowers, and are faintly zoned with grey-green. In the excellent monograph of the hardy Cyclamen by the Rev. W. Wilks, M.A., which was read at the meeting of the Royal Horticultural Society on January 13, 1891, and was published in the *Journal of the Society*, Vol. III., Part 2, Mr. Wilks says, "scent unrecorded." It has, however, a slight, but perceptible, odour, though not nearly so fragrant as some of its congeners. Mr. Wilks also informs us that it is a near relative of *C. europæum*, from which it is, according to the late Mr. Atkins, distinct because of its sharply pointed petals or calyx segments, and by the roots proceeding from the centre of the

corm. This little Cyclamen is probably perfectly hardy. It succeeds here under the shade of small deciduous trees. My tubers were planted in September, 1902, on their arrival from Mersina, and they are in light sandy loam with the addition of a little lime rubbish. S. ARNOTT.

Carsethorn, by Dumfries, N.B.

SAXIFRAGA FORTUNEI.

THIS attractive Saxifrage, referred to in THE GARDEN of the 22nd ult., as in flower at Kew, is so nearly hardy that there must be many in the south who could hope to grow it with perfect success in the open with a little care in the most severe winters. I cultivated it on a rockery facing south-south-east for several years, and during that time it survived several winters which were fatal to plants of greater reputed hardiness. It seemed, like many other plants, to suffer more from wet, succeeded by sharp frost, than from a dry cold, and it was simply owing to having omitted to follow my usual practice of covering the plant with a sheet of glass and putting a small mound of fibrous material about the crown that I eventually lost it. I hope to replace it before long. Its late flowering is one of its greatest claims upon us, but it pleases everyone with its panicles of white flowers, of a form far from universal in the genus. Its leaves, as Mr. Osborn remarks, are rich dark green, and set off the white flowers well. Those who know *S. cortusefolia* will have an idea of the appearance of its congener *S. Fortunei*.

Carsethorn, by Dumfries, N.B. S. ARNOTT.

VERNONIA ARKANSANA.

THE Iron Weeds, a group of tall-growing Aster-like composites from America, introduced to our gardens long ago, do not seem to have become very popular, although they are effective enough flowering with colonies of Asters at this season. The best of those in cultivation is *V. arkansana*, a sturdy, bold-habited plant, 5 feet high, whose giant heads of the richest rosy purple colouring have been much admired by many of late. The flowers are three-quarters of an inch across, and are produced in flattened cymes containing many hundreds, the individual flowers being composed of a disc of short-petalled florets and an outside "ray" series of long-tubed fringed ones, reminding one of the common Cornflower in the petal arrangement. It is an effective border plant, particularly when associated with *Pyrethrum uliginosum* and Asters of the *Novii Belgii* and paniculate section, keeping all *Kniphofias* of the *aloides* section well away from it, or the purple will appear "hard." I do not know what feature gave the plants their popular name; their roots justify it in their toughness, and there is a ruddy bronze tone about the leaves and stems. It lasts a long time in flowering condition—about six weeks of the Aster season—and one may expect it to outlive 99 per cent. of all garden plants. G. B. M.

USEFUL DWARF POLYGONUMS.

THE name Polygonum is usually associated with tall and coarse-growing weedy plants, of which few are worth a place in any garden. Of a different type, however, are the three dwarf creeping species from the Himalayas, two of which are perennials, while the other one is annual. Although they have all been in cultivation for a long time they are not seen so often as their merit deserves. The best known, perhaps, is *P. affine*, a plant peculiarly adapted for covering tree roots and rocks with its trailing shoots, where it will flourish and flower continually for several months. It is under these conditions that it is found growing in its native habitat, where it grows luxuriantly on moist rocks. Moisture, however, is not essential, as with partial shade it will do in rather dry places where little else will grow. With a close mat of evergreen foliage the rosy red flowers are borne on stems about 9 inches in height. Similar to the last in some respects, but a more refined-looking plant, *P. vacciniifolium* does not grow so tall. It will spread rapidly in congenial moist conditions amongst stones, soon occupying a

considerable space and producing its rosy-coloured flowers in profusion on stalks a few inches high. As it does not begin to bloom till September it helps to brighten the rock garden when flowers are very scarce in the late autumn months. The other species, *P. capitatum*, is an annual, very useful for carpeting the bare ground either on the lower parts of the rock garden or beneath taller growing plants in beds. Although cut down by the first frosts it sows itself, seedlings appearing thickly in the late spring. These grow rapidly and soon cover the ground, while the globose heads of pink flowers commence to show soon after midsummer. W. I.

STOKESIA CYANEA.

THERE are two distinct forms of this exceedingly popular plant, one form that flowers in the beginning of winter and another that flowers in August and throughout autumn, the latter being obviously the better garden plant. It makes a close tuft of Plantain-like leafage, producing many rich Cornflower blue heads of showy flowers that resemble *Victoria Asters* in size and in the deeply cut petals, while the shape of the flower is that of *Centaurea*. A colony of strong plants give a wonderful display in the autumn flower border, and one can use the plant to good effect on large rockeries. This early-flowering form never seeds under cultivation so far as my experience shows, and imported seeds of *Stokesia* have always given me the tardy and useless variety, which seems a hopeless plant for English gardens. It is a very hardy species, thriving well with quite ordinary treatment, and propagation is only possible by division of the clumps. G. B. M.

GARDENING OF THE WEEK.

FLOWER GARDEN.

WINTER PROTECTION.

WHEN November sets in it is time to prepare for the winter. All tender plants which are to remain out of doors must receive some protection. In many places it is necessary to draw up the leaves of *Kniphofias* (*Tritomas*), tie them together, and cover the crowns with a layer of leaves or ashes. After the first frost the leaves of *Gunneras* should be cut off, and these, minus the stalks, inverted over the crowns will be found sufficient protection in the southern counties. Where the cold is more severe the crowns may be covered with dry Bracken, which can be kept in place by lacing long sticks, with their ends in the ground, over the Fern.

Plants which suffer more from excessive moisture than a low temperature will be the better if a small heap of broken coke is placed around their stems. But in most cases there is nothing better than Nature's covering—a good layer of leaves. A fairly close layer of leaves 3 inches or 4 inches thick will keep out a very hard frost and much of the rain. A sprinkling of soil will keep them from being blown about.

I have found the following plan most successful for protecting young trees and shrubs. Enclose the plant with wire netting, small meshed if there are rabbits about, leaving about 9 inches clear around the plant. Put in about 4 inches of leaves, and on the top of this loosely place some Bracken; the amount will depend on the nature of the plant. If it is deciduous and considered very tender, I should place the Bracken around the whole of it. With evergreen shrubs less Bracken should be used, and finally stick into the soil around the plant a few large branches of some hardy evergreen, *Rhododendron ponticum* for choice. This will in most cases give ample protection, and also admit a fair amount of air and light.

GLADIOLUS.

The corns of these should now be lifted, leaving about 6 inches of the stem. They should be hung up to dry before being finally stored. The bulbs

of *Galtonia* (*Hyacinthus*) *candicans* and the roots of *Tropæolum tuberosum* and kindred species may also be taken up and kept in a frost-proof shed.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

WINTER-FLOWERING PLANTS.

OF these there is a great variety used for both conservatory and room decoration. The object, after getting them into flower, should be to prolong the period during which they will continue in full beauty, and to do this the requirements of each should be considered. None, perhaps, more than the *Chrysanthemum*, at the present time, will demand such attention, and while on the one hand, especially during fine weather, these plants require a fair amount of water at the root, care in its application must be exercised to avoid any undue spilling of water about the floors and stages of the house in which they are in flower. Clear water should be applied regularly, as the foliage must not be allowed to flag or the soil in the pots gets too dry. Give air, but in suitable weather. Avoid draughts and maintain a buoyant atmosphere by the judicious use of fire-heat.

PRIMULAS, PELARGONIUMS, BOUVARDIAS,

and *Cyclamens*, which continue to make growth and are throwing up fresh flowers, require a fair amount of water at the root, with occasionally a little stimulant, either solid or liquid. Maintain a buoyant atmosphere by the careful use of fire-heat, and admit air on all occasions that are favourable. *Daphne indica*, the flowers of which will last a fair time in perfection with proper care, should be kept in a perfectly cool and airy temperature, and be given water sparingly at the root.

BEGONIA GLOIRE DE LORRAINE.

The flowers of this are now opening freely; it should not be given a too moist atmosphere or a very high temperature, 50° to 55° being quite high enough, with a little air on bright sunny days. This plant being grown, as it generally is, in small-sized pots, requires plenty of feeding, and for this purpose use the following: Clay's Fertilizer, liquid made from cow and sheep manure, as well as soot-water.

RHODODENDRON PRÆCOX.

This can with great ease be had in flower by Christmas, or even earlier. For this purpose a few plants, the growth of which has been thoroughly matured, should be placed in ainery that is just being started, or in a house the temperature of which is not allowed to rise above 45° to 50°. A gentle syringing of the plants in a low temperature, with the admission of air to check the damp, will make the flower-buds swell without inducing the young growth to start. Immediately the buds are half open afford more heat and air to bring them quickly into flower. The flowers will come a brighter colour, and last much longer in good condition, providing that abundance of air is admitted directly the flowers are open.

J. P. LEADBETTER.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

POT VINES.

IF ripe Grapes are required by the middle or end of April the house and Vines must be prepared for starting. Select well-ripened canes with plump-buds of the varieties Black Hamburgh, Foster's Seedling, and Madresfield Court; all these answer well for early forcing. Remove a little of the surface soil from the pots and replace with good fibrous loam, wood ashes, and a sprinkling of some approved Vine manure. The house should be light and airy, adequately heated, and facing south. Make up a bed of fresh leaves, and place the Vines on inverted flower-pots or pedestals of bricks, and fill to the rims with leaves. Make firm, taking care that the bottom-heat does not exceed 65°. Tie the canes down horizontally near the surface of the bed until the buds break, and keep the house closed for the first fortnight without any fire-heat unless the nights are very cold. After

then give a temperature of 50° at night until the buds break, increasing the temperature to 55° as the buds increase in size, with the usual rise from sun-heat during the day. Keep the atmosphere of the house moist by occasionally syringing the canes with tepid water, according to the weather, and afford enough water only to keep the soil moderately moist until the buds break, as too much water at first causes many of the roots to rot.

EARLY PERMANENT VINES.

These having been pruned and cleaned need not be started until the end of the month or beginning of December. In the case, however, of young Vines which have not been forced previously, a longer time should be allowed for them to break. Tie the canes down, keeping the points low, syringing the Vines two or three times daily according to the weather to keep the atmosphere moist. Examine the borders, and if rather dry water with tepid water. Protect outside borders from frost by covering them with leaves, afterwards placing spare lights over them to keep off heavy rains. Prune later Vines, and clean the houses as soon as they are cleared of Grapes, as advised in the calendar of September 17, so as to give them as long a rest as possible. Top-dress the borders with good turf loam, wood ashes, lime rubble, and bone-meal, with a sprinkling of Vine manure to old Vines.

LATE GRAPES.

Water if necessary, as dryness at the roots is often the cause of the berries shrivelling. Choose a fine bright morning for doing this work, when the ventilators can be freely used. Remove the mulch and thoroughly water, afterwards replacing the manure. Look over the bunches once or twice a week for decaying berries, as during this month Grapes often keep badly owing to falling leaves and climatic changes. Keep the pipes moderately warm, and a night temperature of 50° to 55°. Pay careful attention to the ventilation when the weather is wet or foggy, and keep the house clear of plants that require watering. If only a few bunches are hanging in midseason houses, these should be cut and bottled at once to allow the house to be thrown open, so as to give the Vines as much rest as possible.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

THE spell of dry and mild weather still continues. There has been no frost to do any damage at the time of writing. Those alive to the benefit of pushing forward the work at this period will have got the garden into a trim and tidy condition before winter, and have cleared the ground of the various root crops—Beet, Carrots, &c. Push forward the work of preparing manure for the kitchen garden and many other operations that can be best carried out at this date.

CELERY.

The final earthing up should now be given, and should be done in the most careful manner. The soil must be broken finely with the spade, and carefully packed round the plants to within 6 inches of the top of the leaf-stalk, beating the surface smooth with the spade. Should rain water be inclined to lie at the bottom of the trenches between the ridges the soil should be loosened. A quantity of dry covering material—Bracken, straw, or such like—should be in readiness for placing on the top of the ridges in the event of severe frost.

CAULIFLOWER.

Those from the very latest sowing will, in this exceptionally mild autumn, be found to be the most suitable for transferring into frames. Those who have delayed the work till now will be most likely to bring the plants through the winter in the right condition. Those recommended to be sown in August are now by far too large, and September-sown plants are most suitable. After they have been placed in their winter quarters give a good watering. The sashes may be left off until frost appears. Beautiful heads of Autumn

Giant are still plentiful. The leaves should be broken over the heads as protection against frost.

HORSE RADISH.

Where this has become weakly a new bed may now be formed. Beds in most cases should be renewed every three or four years, or a portion of the plot replanted every season. Make sure that every piece of the old roots is forked out. Give the land a thorough trenching with plenty of good farmyard manure worked in. A sufficient quantity of the thick roots should be kept to make the new plantation. The remainder may be stored in sand for use throughout the winter. See that all the small and useless roots are removed from the ground, as it is a plant difficult to eradicate. The ground must be very carefully forked over, and the manure should be placed at the bottom of the trenches only.

Hoptoun House Gardens,

THOMAS HAY.

South Queensferry, N.B.

ORCHIDS.

CIRROPETALUM PICTURATUM.

THIS interesting Orchid is now growing apace, and the requisite repotting or resurfacing may be safely carried out, its habit of growth being such that it soon overgrows its receptacle, yet in this case I do not advise potting on that account if the compost is sweet. Although it is somewhat difficult to place this plant nicely in a small pot, yet I prefer a pot to a shallow pan. Nearly half fill it with chopped rhizomes; the roots are best placed where they have a deep rooting space. The compost should consist of equal parts of fibrous peat and chopped sphagnum; pot rather lightly, keeping the material low enough to allow of a sphagnum surfacing. When finished the surface should be on a level with the rim of the pot, and the rhizome growth of the plant being on the top, the growths can be drawn considerably to the centre of receptacles with the aid of wire pegs. Suspend them in the most humid part of the intermediate house; heavy waterings are not desirable. Damping of the surface moss after one good watering to settle the compost will keep sufficient moisture in the compost during the winter months.

CIRROPETALUM THOUARSII AND C. MEDUSA.

The growth on these beautiful and quaint forms is now completed. Water should only be given when the plants become fairly dry, but do not allow them to become so dry as to cause shrivelling. Place them in the warmest part of the Cattleya house, so that all available light reaches them.

RESTREPIA ANTENNIFERA.

Well-grown plants of this pretty botanical Orchid are in flower during most of the year, and it is well worthy of a place in every collection. The Odontoglossum house suits it, but during the winter months water should be given very sparingly. Ours are grown with the Masdevallias, and the treatment afforded is very suitable, viz., only water from now till the end of February, when they have become very dry. Potting may be done now if the young growths are started. If not, it is best deferred till new basal growths are visible, using a mixture of two parts peat, two parts sphagnum, and one part leaf-soil mixed with some small crocks and coarse sand. The pots should be nearly half filled with rhizomes. This species does not require potting often. Surfacing suffices unless the compost has become soured.

LÆLIA MONOPHYLLA.

This beautiful orange scarlet-flowered Orchid, although miniature in growth, is very attractive, and it lasts in flower for a considerable season. If it could be imported in quantity it would soon become very popular, and prove of considerable value to those interested in hybridising. The flowering season is now over, so they will require very little water till the early spring months. Any moss that may have overgrown the small, slender bulbs should be removed to allow the light to reach the basal dormant eye. A temperature a

little higher than that which the cool house affords is most suitable both now and during the growing season.

LÆLIA HARPOPHYLLA

is now growing freely. The compost for well-rooted plants should be kept fairly humid by lightly damping over the surface moss; heavy waterings are very injurious. To obtain the best flowers place the plants well up to the light in the intermediate house. Whenever possible damp freely between the pots. This Lælia is a most useful buttonhole Orchid, and one that if given fair treatment will flower freely and prove very desirable during the early spring months.

FRAGRANT CARNATIONS.

REPLYING to T. W. Harris (THE GARDEN, page 281), I think there are many scented Carnations still in cultivation. It is, no doubt, a fact that many of the newer varieties have little or no scent. This especially applies to scarlets and yellows of the smooth-edged type. In fact, there are very few yellows with a powerful perfume. The old Andalsia, pale yellow, with fringed petals, was scented, but this variety seems to have gone out of culture. Miss Audrey Campbell is slightly scented. We get the most powerful scent in the crimson. The old crimson Clove is perhaps still the most powerfully scented. Uriah Pike has a very pleasant perfume, and Countess of Warwick is also a good free-flowering variety with a pleasant Clove scent. H. J. Jones, a fine crimson, which appears to be a hybrid between the old Clove and the Malmaison type, has a strong scent. All the true Malmaisons are fragrant, and this is perhaps their greatest charm; but there are now many put with this section which I should hardly consider belong to them, and which, if not entirely devoid of scent, have very little. Those which I should recommend are Princess May, deep pink, and a better grower than most; Trumpeter, deep scarlet; Lady Grimston, bluish white; and Lord Rosebery; and to these might be added several others. There is no white Carnation to beat Gloire de Nancy for scent; it also has large full flowers and vigorous growth. Mrs. S. Brooks is the best white for pots or winter flowering, and has a pleasant perfume. There are several other good whites. In the scarlets it is more difficult to find scented varieties. Cantab, an old variety of the border section, has survived many others on account of its scent. Many of the pink varieties may be selected for their scent. Mary Morris, an old variety, is still worth growing. Duchess of Fife is perhaps better known now, and is in every way a good Carnation. Of those for pots Mme. Therese Franco (or Mrs. Leopold de Rothschild) is good.

The American varieties are now extensively grown for market, and, in addition to making good stems, all are sweet scented. When these were first introduced there was some prejudice against them on account of the fringed petals; but this has been overcome, and they are now much appreciated, the large flowers, good stems, and pleasant perfume being qualities we all admire. We are continually getting new varieties, but of those which have been well tried Mrs. T. W. Lawson, rose-pink, is one of the best; G. H. Crane is a good scarlet; Harry Fenn, deep crimson; Sybil, pale flesh; Queen Louisa, pure white; Governor Roosevelt, crimson; Norway, another good white, particularly powerful scented; Floriana, pink; Alpine Glow, salmon-pink; Fair Maid, pink, somewhat the same shade as the old favourite Miss Joliffe.

Within the last few years several good varieties of similar habit to the American sorts have been raised by English growers. Names are so numerous and varied that it would be difficult to give a full list, but I think Mr. Harris will be able to find a good many among our newest varieties which are as fragrant as any of the older sorts, but he must not look for these among the large smooth-petalled varieties. Almost all those with the fringed petals are scented. In Messrs. Veitch's collection shown at the Royal Horticultural Hall some weeks ago I noted Prosperity, large fringed flowers, white, a rosy pink shading in centre, as one of the most powerfully scented in the collection. In most of the deep crimsons the scent is good. Many whites will be found to possess the quality, but in scarlets and yellows there are many which have no scent. Some of the dull reds or salmon shades which I noted in Messrs. Cutbush and Sons' collection have the desired quality, and I believe most raisers now aim at securing scent as one of the most necessary qualities. The old crimson Clove is one of the best to work from, and Gloire de Nancy, the pure white Clove, is equally good and powerfully scented.

A. HEMSLEY.

IF your correspondent T. W. Harris will procure a copy of "Sweet-scented Flowers and Fragrant Leaves," price 3s. 6d., from Messrs. Sampson Low, Marston and Co., Fetter Lane, E.C., he will find all he wants to know about sweet-smelling Carnations.

DONALD McDONALD.

Bealey Heath, Kent.

FRUIT TREES ON LAWN.

FEW trees are more ornamental or give greater beauty in pleasure grounds in both spring and autumn than fruit-bearing trees, yet how few of them are planted for this purpose. Crabs and various Apples give beautiful flowers in spring and richly coloured fruit in autumn, and some Apples give good eating fruits also, as do some of the more recently-raised Crabs. Two varieties that recently received awards of merit, Veitch's Scarlet and Frettingham's Victoria, while very free fruiters and giving fruits of good size and colour, are very pleasant eating sorts. For colour alone the Siberian, John Downie, and especially the Dartmouth Crabs are very effective. I saw recently in front of the manager's house at Veitch's Langley nursery a tree of medium size laden with bright-coloured fruit, Crataegus orientalis, that formed a singularly beautiful object. But of larger fruits there are among Apples some that give brilliant colour. Those who have been privileged, as I have been recently, to look through some of our great fruit nurseries, and note the rich colouring found here and there, must have felt that such trees merited positions as lawn specimens. Six specially rich coloured varieties are Duchess Favourite,

Worcester Pearmain, Colonel Vaughan, Baumann's Red Reinette, Jolly Miller, and Crimson Queen-ling. To this list may be added Gascoyne's Scarlet if a larger fruiting variety is preferred. Colour would in many cases be better on lawns than on rich cultivated soil. Apart from the fruit, Apple or Crab bloom is most beautiful. A. D.

NURSERY GARDENS.

MESSRS. S. S. MARSHALL, LIMITED,
BARNHAM.

FRUIT trees form the chief feature in the Sussex nurseries of Messrs. S. S. Marshall, Limited. They are grown upon exposed land near Barnham Junction, on the London, Brighton, and South-Coast Railway, and about two miles from Bognor. Altogether some eighty acres are devoted to the culture of nursery stock, and the greater portion is occupied by fruit trees. To give some idea of the quantities, we may mention that some fifteen to

Twenty Thousand Trained Fruit Trees are grown annually, as well as a very large stock of Apples, including some 50,000 two year old trees, quantities of Pear trees on the Quince stock, some 10,000 standard Cherries, and other fruits in proportion to their importance. The fruit trees throughout the nursery are distinguished by their sturdiness and vigour. After such a splendid season as we have had one would of course expect them to be looking well, but it is hardly too much to say that they could not look better; both soil and climate apparently suit them well. Trained trees are particularly good, as, for instance, the cordon Pear trees shown in one of our illustrations, and the fan-shaped and standard Cherry trees. The young specimen Pear tree that we also show is but one of many hundred similar trees. Trained Peach and Nectarine trees are largely represented by excellent stock, and we may say the same of the bush Apples; the latter are largely raised for market growers.

ROSES IN NOVEMBER.

One of the prettiest sights in the nursery a few days ago was a row of China Roses, flowering quite freely, as may be seen from the photograph we have reproduced (see page 303.) It is the old pink China, and needs no word of recommendation, for it goes without saying that a Rose that will bloom all the summer and still be beautiful in November should be in every garden.

Although Roses are not such an important item in the Barnham nurseries as fruit trees, still they are largely grown, and the stock is being rapidly increased owing to the great demand. We saw some 30,000 to 40,000 dwarfs and 8,000 standards, all the best of the newer sorts, as well as the good older varieties being included.

Among the trees and shrubs grown in these nurseries we were most impressed with the splendid specimens of

CUPRESSUS MACROCARPA,

15 feet to 18 feet high, pyramids of bright green. Numbers of these are planted in the shrubbery, on either side the chief drive through the nursery, and they make a very handsome addition to it. Messrs. Marshall make a speciality of trees for sea-side planting, and Cupressus macrocarpa is one of the best of them. It is a tree that requires careful treatment before it is finally planted. It is transplanted in the spring and lifted again in the autumn, so that the long fleshy roots may not go deeply in the soil. The yellow variety (C. m. lutea), the most beautiful of all golden conifers, is well grown here too. Like the type, it thrives best by the sea. Cupressus macrocarpa and its yellow variety are chiefly grown in pots, because of the difficulty in transplanting them. Other conifers here worth drawing attention to are Thuya Lobbi, Cupressus lawsoniana, C. l. erecta viridis, C. l. Fraseri, and C. l. Aluminii.

Among other trees for seaside planting we might mention evergreen Oaks, Escallonias, and

HARDY FUCHSIAS.

Messrs. Marshall have an exceptionally fine lot of the latter, Riccartoni and gracilis chiefly being grown. At the time of our visit these hardy Fuchsias were masses of colour. They certainly deserve to be extensively planted.

THE MYROBALAN PLUM

is another plant we might well call attention to, and especially with regard to its value as a hedge plant. It grows more quickly than the Privet or Quick, although it does not make such a dense hedge as the latter. It might often be planted with advantage instead of the Privet. There are nearly 100,000 plants of this in the Barnham nurseries. There are large quantities also of Privet, Quick, Euonymus, green and gold, and other hedge plants. We might further mention as receiving special attention Choisya ternata, Olearias, particularly O. Gunnii, and Cotoneaster, especially microphylla and horizontalis, both of which make handsome bushes. It is interesting to learn that

THE SHASTA DAISY

has much improved upon further acquaintance. We were told that it had been magnificent this

A BUSH PEAR TREE IN THE BARNHAM NURSERIES.

year, and it was still in bloom a few days ago. Herbaceous plants, such as Phloxes, Asters, and others, are cultivated in quantities, and the stock of Roses, Clematises, Honeysuckles, and Jasmines in pots is also considerable. We were surprised to see Solanum jasminoides doing so well out of doors, both as a bush and clambering over a wooden trellis. The stem carried numerous bunches of its beautiful white flowers, and there were many buds that would open were frost to keep away.

AUTUMN ROSES AT BATH.

A FEW weeks ago the Roses were making a beautiful display in the nursery of Messrs. Cooling and Sons at Bath; the sight of those that were still in blossom made one regret not having been among them in Rose time proper. The huge specimens of Rosa polyantha grandiflora must have been a grand sight when in flower, and the weeping standards of wichuraiana Roses have been worth

going far to see. Even at the time of our visit the latter still were in flower. The day cannot be far distant when these delightful Roses will be extensively planted in every garden; they are most suitable for training over arches. The French hybridists are chiefly responsible for the best varieties, such as Alberic Barbier, Gardenia, and René André, though Dorothy Perkins is a notable exception. Most of these are evergreen, and even when not in flower are very pleasing plants to have in the garden. We saw the old Macartney Rose very beautiful on a low wall. It does particularly well in the neighbourhood of Bath. The large, single, white flower, the bud enclosed within curious grey-green sepals, and the fruit were all to be seen on the plant together. Those who want a reliable

COMPANION ROSE TO CRIMSON RAMBLER

should, Messrs. Cooling say, plant Mme. D'Arbly. It bears double white flowers which appear at the same time. This lovely climbing Musk Rose may be trained up a pillar or used as a climber in many other positions. Two other good climbers that are always in flower, more or less, are Alistair Stella Gray and Mme. Alfred Carrière. No garden where climbing Roses are planted should be without them. That famous Rose G. Nabonnand was still finely in bloom when we were at Bath, and it was expected to continue flowering until Christmas.

MILDEW NEVER ATTACKS THIS ROSE,

which is a point greatly in its favour; at least this is the experience of Messrs. Cooling. Not the least attractive feature is the lovely bronze-red tint of the shoots. As might be expected the old Monthly Roses, pink and crimson, made one of the prettiest displays in the nursery. Other good autumn flowering varieties that one could not fail to notice were Ards Rover, a climber with rich crimson blossoms, and standards of Ulrich Brunner, Tom Wood, Frau Karl Druschki, and Maréchal Niel. The latter were very beautiful.

COOLING'S CRIMSON SINGLE BEDDER

is a Rose worth planting, and so is climbing Mrs. W. J. Grant, a most profuse flowerer. Rosa Brunoni himalaica is a lovely Rose (introduced by Messrs. Cooling) with large bunches of single flowers. For an abundance of blossoms Grüss an Teplitz is not to be beaten. Among the best

ROSES OF RECENT INTRODUCTION

are Bellefleur, a single scarlet, that makes an excellent pillar and hedge Rose, very free; Ards Pillar, rich velvety crimson, a splendid pillar Rose; La Tosca (H.T.), soft pink, tinted rosy white and yellow, very free; Sénateur Belle (H.T.), pale salmon with deep yellow centre; Yvonne des Buifards (Tea), pale rose, carmine at edges of petals, centre shaded with amber;

COOLING'S YELLOW NOISETTE,

a beautiful new yellow climbing Rose, the flowers produced in clusters, very beautiful in the bud; and Helene Welter (H.T.), bright rose, buds long, very free. Such are a few of the 100,000 Rose trees grown in the Bath nurseries of Messrs. Cooling.

They cultivate fruit trees largely also. Cherries and Apples are particularly good. One of the favourite early dessert Apples, and at the same time one of the most handsome, is Beauty of Bath, which originated in Messrs. Cooling's nurseries. The standard Pears are a feature here. Messrs. Cooling use a special stock which makes a clean straight stem, and without this a standard tree loses much of its attractiveness and value.

APPLE ISIDORE DUPONT.

This Apple was obtained from some chance seedlings by M. Arnou Pellerin of Bagnolet, France. Up to the present time Emperor Alexander has been most generally cultivated as a September dessert Apple. It owes this privilege, however, much more to its beauty than to its quality. Isidore Dupont, although it ripens a few days later, appears to us to be certainly destined to take the place of the other. It is of superior quality, of great delicacy of flavour, as large as Calville

Blanche, and of remarkable colouring. From the shape of its ridged fruit this Apple Isidore Dupont should be classed among the Calville group. It is fertile, and has, as yet, only been grown as an espalier. Apple Isidore Dupont was placed before the fruit committee for fruit tree cultivation de la Société d'Horticulture de France, at the meeting on October 8, 1903, and was very favourably commented upon. At the exhibition in November of the same year the jury awarded it the silver medal (the highest award) for new fruits shown by the grower.

J. M. BUISSON, in *La Revue Horticole*.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE HERBACEOUS BORDER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I have just seen an article in your issue of the 8th ult. by Augusta de Lacy Lacy on the making of a herbaceous border, which I cannot help thinking might dishearten and mislead a beginner.

While recognising that there is much useful information in the article, I venture, nevertheless, in the friendliest possible spirit, to draw attention to a few of what I consider are mistakes. In the first place, it is not in the least necessary to take the soil out 4 feet, and put 1 foot rubble, covered with a layer of ashes, at the bottom. I do not deny that the deeper the soil is the better, and of course the ground must be drained, but this will probably have been done when the garden was made. Then the idea of being careful only to obtain manure from a farmer who farms "high" is rather misleading. Any ordinary farmyard manure is quite good enough, and not too much of it. A gardener I once had was ingenious enough to even kill most of my Michaelmas Daisies, to say nothing of my choicer plants, by planting them in nearly solid farmyard manure.

Now as to the width of the border, the writer suggests 6 feet to 7 feet, which of course is not nearly wide enough; 12 feet wide is the very least a border should be if anything like a succession of flowers is to be kept up from spring to autumn. Then it is proposed to plant Lilacs, Laburnums, Weigelas, Syringas, and, forsooth, a few Japanese Maples at the back. Of course, none of these should be in a border only 6 feet to 7 feet wide, though they would be quite allowable in a border, say, 16 feet to 18 feet wide; but even then choicer shrubs like Japanese Maples must not be planted among hungry shrubs and behind plants which grow three times as high. In front of the shrubs it is proposed to plant Phloxes, which would be entirely hidden by the Delphiniums, Lupins, and Galegas, which are to be planted in front of them. Few of the choicer Phloxes grow more than 3 feet to 3 feet 6 inches high nowadays, and should be in the same row as the Pæonies, *Erigeron speciosus*, *Monarda*, *Potentillas*, and Oriental Poppies—always supposing you will admit these showy but untidy and hungry Poppies into your border. In any case only have the var. *bracteatum*, which is far the finest. *Potentillas* and *Geums*, which are pronounced unsatisfactory and straggling, are amongst the most showy of the summer-blooming herbaceous plants. *Potentillas* certainly require careful tying up, and this is best done with dead Larch branches inserted round and over the plants when they have grown about 1 foot high. I cannot agree that the old-fashioned *Columbines* are more effective in a border than the beautiful spurred *Aquilegas*, though the double var. *Munstead White* is well worth growing; the others are hardly worth the room they take, and they sow themselves everywhere. Several *Campanulas* are placed in the second row with *Achilleas* and *Galegas*; but how is the unfortunate beginner to discriminate among the scores of *Campanulas*, and to know that about the only variety he ought to associate with these two weedy subjects is *Campanula macrantha* in its blue and white forms. To talk of *Campanulas*, as also

of *Spiræas*, *Pæonies*, and *Iris*, is altogether too hazy for a beginner, who should be told, for instance, that the second and third rows should contain, say, *Campanula persicifolia*, the var. *grandiflora alba* and *Moerheimi*, *C. grandis*, *C. lactiflora*, *C. glomerata dahurica* (rather a weed), and the *Canterbury Bells*. Personally, I am thinking of banishing all these *Campanulas* from my summer borders, as in a hot summer the flowers hardly last a week; in fact, this year the *Canterbury Bells* were over before they were out. All the ordinary *Campanulas* grow best in shade, and the best group of *C. grandis* I ever saw was growing under the dense shade of a Cedar tree.

To revert to one or two other plants named, I should say do not plant *Heuchera sanguinea*, it is too uncertain except in a dry year; far better grow *H. brizoides gracillima*, which was out with me this year for quite three months. Next year I am going to promote it to a bed in the flower garden, and mix it with *Linum narbonense* and *Stipa pinata*, which I think might be a good combination. *Eryngium amethystinum* is a rock plant, and not very easy to get true. *E. oliverianum* is probably the plant meant. *Lilium longiflorum* will bloom for one year, and its non-appearance next might disappoint the beginner. Do not plant Ribbon Grass; if you want a variegated grass, far better try *Arundo Donax variegata*, which is much handsomer and quite hardy in the South and Midlands. *Elymus arenarius* is much prettier than Ribbon Grass, and no more of a weed. By all means have a few Foxgloves, but be careful to cut off the seed heads, and remember they are wild flowers, and will sow themselves all over the garden. After enumerating a certain number of flowers, the writer says: "You have now collected every available plant to give you colour from April to October," whereas you have really only touched the fringe. Where, for instance, are the Lilies, *Alstroemerias*, *Kniphofias*, *Eremuri*, *Ostrowskya*, *Clematis erecta*, *Thalictrums*, *Rockets*, *Mulleins*, *Echinops*, *Linums*, *Sidalcea Listeri*, *Romneya Coulteri*, *Fuchsias*, *Statice*, &c. Every decent border should contain these, and at least the following Lilies:—*Umbellatum*, erectum elegans, or *thunbergianum*, *szovitzianum*, *testaceum*, *croceum*, *pardalinum*, *candidum*, *tigrinum*, and *Martagon*, if you like the colour of the last. All these, except possibly *candidum*, can be grown in any border.

Personally, without going as far as Bacon, who would have a garden for every month of the year, I am not in favour of "three-season borders," as it is hardly possible to have one border really bright from March to October. I have one border for spring-autumn, one for spring-summer, and one for summer-autumn. In conclusion, I would say

only plant the best of everything, there are plenty of good things nowadays without growing weeds. Shun like the plague such things as *Polygonums*, French Willow (*Epilobium*), *Helianthus* Miss Mellish, Winter *Heliotrope*, *Campanula rapunculoides*, &c., and if you will have Golden Rod, *Achilleas*, *Galegas*, *Pyrethrum uliginosum*, &c., use them sparingly, and keep your eye on them.

M.

TROPEOLUM SPECIOSUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In support of "A. D.'s" advice to owners of gardens to persevere in the cultivation of this beautiful climber in whatever position or aspect the garden happens to be, I may, perhaps, say that I have seen the plant in splendid condition and flowering freely both in South Devon as well as in the more northern part of the county. Nicholson in his "Dictionary of Gardening" says that it "requires a constantly moist and shaded position in a peat border, and is impatient of disturbance at the roots." Under such conditions as these I saw the plant in great luxuriance about the middle of August clambering over bushes and occupying a large space in the nurseries of Messrs. R. Veitch and Son at Exminster, having for its close companion *Mutisia decurrens*, which has been in its present position some five years, and was at the time of my visit just finishing a successful flowering season. In close proximity was also a fine clump of *Kniphofia northiana*, bearing the remains of several large flower-spikes. This plant had also

CORDON FEAR TREES IN THE BARNHAM NURSERIES.

been in its present place about five years. In contradistinction to the damp, shady position the *Tropeolum* occupies at Exminster, I saw it about a year ago growing well in an open, sunny border on a terrace at Killerton, the seat of Sir Thomas Acland, a few miles to the north-east of Exeter, where it formed graceful festoons of its brilliant flowers among dwarf shrubs. In my own garden I planted in the late spring a few of the long, creeping rhizomes in a position facing east. The plants have already grown to a height of some 10 feet or 12 feet, and produced several clusters of flowers.

JOHN R. JACKSON.

Claremont, Lymington, near Exmouth.

A FIG TREE IN SARK.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In the grounds of La Seignenrie, Sark, may be seen a Fig tree of great age, trained in the peculiar manner shown in the illustration. It is said to be no less than three hundred years old, and the thickness of the trunk quite warrants this estimate. It is trained over a large flat rectangular framework of wood, supported by stout uprights, giving the general effect of a huge table about 5 feet high. At the time of my visit (August) the tree was in full bearing, and beneath it was a grand bed of Mushrooms. I am indebted to the Seigneur of the Island, Mr. Collings, for permitting the photograph to be taken.

W.

POTATOES TO EAT.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I was very pleased to read in your issue of the 22nd ult. the timely remarks of the Rev. G. H. Engleheart upon Potatoes, and also upon the National Potato Society. The first show of this society at the Crystal Palace has, I think, taught us that some better method of judging Potatoes should be adopted, and that at once. In such a representative society, in my opinion, the Potato should no longer be treated as a purely exhibition plant—that is to say, the staging of tubers alone is of no practical value to anybody. At the exhibition, no doubt, the tubers, with their many coloured labels denoting their name and origin, made a very brave show indeed, but this is not what is wanted. Is it not practicable to exhibit a growing plant, or plants, of any variety, a dishful of its produce as lifted from the soil, and a few tubers boiled? If this were done visitors to the show would have some opportunity of noting habit of growth, productiveness, the general appearance of the tubers, and of testing the cooking qualities. The judges, too, would have some rational method of assisting them in their awards, and much more would therefore be done to prevent the great difference of opinion which invariably results from the present system of judging Potatoes at exhibitions. This is all the more applicable to seedling varieties submitted for the first time to such an institution as the National Potato Society. There was a prize offered at the Crystal Palace show for the best collection of seedling varieties not in commerce. Now, the tubers which were awarded the first prize in this class were, so far as tubers are concerned, all that the most fastidious judge could desire, but what of the other and more essential points—flavour and quality, productiveness, and disease-resisting ability? It is impossible under the present system of granting awards for any judge to form any idea of the most necessary points in Potatoes shown in such a class as this, and in such an important show as that of the National Potato Society. The pedigree, of course, is usually given, but experience has taught us that this is by no means an index to the good points of a Potato.

The fact is the aim of growers is productiveness; quality is apparently of no consideration. If a raiser can demonstrate that his latest introduction is a phenomenon in the way of a heavy cropper, as a general rule, he has satisfied himself, and also the demands of growers, and there, usually, his mission ends. What is the use of growing a variety that will yield, say, 20 tons to the acre, or 170 tubers to the plant, if quality and flavour in that particular variety are con-

spicuous by their absence? Are growers planting Potatoes to feed cattle, and not very discriminating cattle, as Mr. Engleheart aptly puts it, or are they planting them for human food?

Every year it is becoming increasingly difficult to see a well flavoured Potato of good quality upon the table, and I hope that the very able management of the National Potato Society will see to it that in future no new Potato submitted to them will be granted the hall-mark of their society until it has been tested and cooked by them, and is found to contain everything that is necessary to make a good Potato, quality being the first consideration, productiveness the second. Perhaps many of the seedlings submitted to the society were perfect in the above respects, but how could the judges or visitors to the show ascertain this? Heavy cropping qualities and shape of tuber alone are of little value to the consumer, who, in the end, must be most seriously considered, and they must have quality; failing this, it most certainly means a curtailed demand. If Potatoes are not good nowadays there are other things which can and are taking their place upon the dinner-tables of the country.

While on the subject of judging, I was sorry to notice the society at the Crystal Palace show

better Potatoes on their humble tables, I believe, than the great majority of their English consins. Why should this be?

Inveresk, Midlothian.

GEORGE M. TAYLOR.

POTATO NORTHERN STAR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—No doubt, as "G. H. H." says (page 280), that it is disappointing to have an idol shattered, just as it is to have a pet theory upset, but it seems now that Northern Star, the idol of the past two or three seasons, has come into more general culture and the test of quality proved, there seems nothing but disappointment to record. I am not sure that many will have expected very much less, for quality, which after all is the most important point in Potato culture, and use has hitherto been unconsidered. I am quite convinced that when Northern Star has to face the cooking test it will be thrown out by the majority of growers, and the possibility is Eldorado will meet the same fate, for, as Mr. Engleheart says, no one can venture yet to try even one tuber. Now that the "Stars" have come within a planting price for the million, it will probably be abandoned by those who have gambled in money values, and attention

A FIG TREE 300 YEARS OLD IN SARK.

encouraging awards to tubers of great size, quite unfit for ordinary and general cooking purposes. This, I believe, to be a fatal error, and I challenged an award in question at the evening meeting of the society, but I was told by one of the gentlemen who judged this particular lot of Potatoes that I wanted Potatoes judged from an horticultural, and not from an agricultural standard, what they wanted was weight. This is, of course, the new doctrine, and I regret to find the National Potato Society adopting it. Your correspondent also draws attention to the prejudice against yellow-coloured Potatoes. There are many yellow fleshed varieties of great excellence, and I cannot imagine why market growers do not push these more than they do. I maintain that colour is of no consideration if the quality is there, and if the Potato looks white and mealy for the table. I could put on the English market several varieties of coloured Potatoes, both round and kidney shapes, of delightful flavour, something that would be a revelation to present-day consumers, but the colour of the skin debars this. The crofters and cottars in Scotland have

will turn on future novelty with the same aspect in view. Many growers who have been so careful to provide by propagation the largest possible number of plants from their purchases and carefully noted the weight of the actual yield, perhaps have not tried some of the older sorts which have been long under cultivation and given them the same chance of competing. I am quite convinced that almost any older main crop sort would have done as well as Northern Star under the same conditions, and many a good deal better. Disease resistance is nothing but a myth, for from so many come reports of infection. In our case there was more disease in Northern Star than in Snowdrop. Records of varying weights are given as from 40lb. to 160lb. yield from a single pound of seed, some pursuing a natural system of propagation, others by excessive propagation under glass. Out of our crop of 50lb. quite half were no better than pig food, and would have been used as such were they without the element of novelty, and even admitting this there is a doubt as to whether further trial will be given it. Potatoes are grown for table use, not for pigs and fowls, and if there is nothing

better than a lump of soap-like Potato to partake of when cooked, who will continue to grow, sell, or eat them? It is quite true that soil has much influence on the texture and flavour of Potatoes, and not every garden can find the conditions essential to high quality. Not only does Northern Star offend in this important matter, but others of recent origin as well, Evergood in particular being absolutely uneatable and soap-like.

W. STRUGNELL.

Rood Ashton Gardens, Trowbridge.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I agree with your correspondent regarding Northern Star Potatoes. I have tried the variety myself this season, and I have found them very much as he describes. I am far from thinking that it is the perfect Potato we have been led to believe it is. Of course, I have grown it under ordinary culture, similar to my other sorts, and the result was a superabundance of tubers, but a great number of them were seed size and "chats." The land was in good condition and received a supply of farmyard and also a dressing of artificial manure. Other varieties which I grew alongside produced good crops, namely, Evergood, Royal Kidney, and The Factor. The last mentioned I have found a splendid variety, giving well-shaped Potatoes of good size, with practically no small ones, and very few of even seed size. A number of shaws weighed from 5½lb. to 6½lb., and one I had weighed 7lb. 2oz., consisting of eighteen tubers, but the best recommendation of this The Factor Potato, lies in the fact that it is a splendid cooker, and of good flavour, equal to any of the old favourites. Personally I should consider it more likely to become a standard main crop than the Northern Star.

H. E. R.

CHRYSANTHEMUMS AT SWANLEY.

AS each succeeding season comes round we always wend our way to Messrs. Henry Cannell and Sons of Swanley with the full assurance that if there is to be anything new and meritorious in new Chrysanthemums from any part of the world where the flower is known and grown we are certain to see it in their collection. This year forms no exception to the rule, for Messrs. Cannell have a thoroughly cosmopolitan lot of flowers that have been raised by most of the eminent seedling growers, both foreign and colonial, to say nothing of home-raised products. The large show house, a span 165 feet long by 28 feet wide, is just now at its best. The blooms, grown far away in the pure air and clear light of the county of Kent, are clean and bright, and form a most attractive display.

Dealing first with Continental novelties, those of M. Ernest Calvat unquestionably occupy the front rank in spite of threatened competition, which made itself manifest on the part of one of his fellow countrymen last year. The new grower's products, although included in Messrs. Cannell's collection, are somewhat late. M. Calvat's best are Souvenir de père Calvat, a large Japanese, the tips of the florets curly, colour pure white, tinted in the centre, outer florets lilac-purple; Jean Calvat, a Japanese with very long florets, deep golden-yellow, with shading of chestnut-red; Shakers, quite a novelty of this season, a large crimson and gold Japanese; F. S. Vallis, still one of the loveliest flowers in the pure pale yellow group; Nivôse, a very perfect form of Japanese of the Carnot type, but better habit, florets long and drooping, colour a lovely shade of pure bright yellow. Chrysanthémiste Montigny is one of the present year's set; it is immense in size, a very broad flower, florets grooved and twisted, colour pure pale primrose-yellow. President Viger is a large-sized Japanese with great length of floret, rosy pink, with silvery reverse. Mlle. E. Chabanne is another typical Calvat bloom, deep in build and of fine globular form, colour pale rosy pink. Mlle. Marthe Morel, like the preceding, is one of the 1903 set, a Japanese with very fine florets of good size, and pure white in colour. Sapho belongs to

the current year's set, a very large Japanese with broad florets, colour rosy plum, with reverse of silver. Very pure white is found in Mlle. Anna Debono, which is one of the newest seedlings raised by this eminent grower.

There are seedlings from several other French raisers, but the only one of any serious importance as shown by the Swanley collection is our old friend M. Aug. Nonin, who has already supplied the English grower with a fair proportion of good exhibition sorts. But M. Nonin does not limit himself to the production of one class of flower only, as we shall show presently. He has sent out recently in the large flowering section Josephine Roux, a fine Japanese of good form, with long, drooping florets, colour purple-amaranth, reverse silvery; Mme. Marguerite Guiot, not over large, but a very full flower, pure paper-white in colour, and an October-blooming variety. Amateur Consieul is also one of M. Nonin's, a very close, compact bloom of excellent form, having rather narrow florets, colour a fine shade of velvety carmine-amaranth. Chas. Schwartz is from the same source, a deep rich-coloured crimson, but, in spite of its broad florets, we do not think it will do more than become a useful variety for decorative groups where richness of colour is desired. M. Nonin is a capable exponent of the art of arranging effective and artistic groups, and his exhibits at the Paris shows have always been marked by the greatest taste. We are not, therefore, surprised to find him contributing a new collection of purely decorative varieties, for which there is a considerable demand in this country. Some of these were in fine form when we were at Messrs. Canoll's, all of them being of good habit, free flowering, and most useful novelties where general effect is required. We specially note Le Gracieux, silvery pearly pink; Acajou, deep red; Innocence, a pretty white; Jason, lemon-yellow; Etoile Blanche, pure paper-white; Primevère, rather above the average in size, soft pale yellow, shaded buff; Etoile d'Or, bright golden-yellow; and Le Pactole, golden-yellow, shaded bronze.

Other varieties of equal merit and from various sources, including Australia, are Jessie, a nice Japanese, with long drooping florets, colour deep yellow shaded crushed strawberry; Mrs. W. Higgin, a big globular bloom with grooved florets twisted and intermingling, colour pure white; Byron, a charming flower with very narrow florets, close in build, a pretty shade of lilac-mauve; Mrs. J. Hadaway, the sport from Miss Mildred Ware; and several others, such as Beatrice May, soft blush; Major Powell Cotton, deep golden-yellow, slightly suffused bronze; Lady Hopetoun, silvery lilac-pink; Mrs. J. Duon, the new white; Lady Conyers, &c., might also be deemed worthy of special mention.

Varieties of highly coloured shades are numerous and uniformly good. Thus, Alfriston, a fine Japanese with medium-sized florets, is strongly in evidence; its rich bright dazzling crimson and old gold reverse making it one of the most effective of its kind. Mrs. H. A. Allan is of good size, the colour purple-amaranth, with reverse silvery. Red Barkley is another fine addition to the crimsons.

In yellows most of the well-known recent additions are included, one of the finest being unquestionably Mrs. Harry Emmerton, the size of which strongly recommends it as eminently suitable for the show-board. Bessie Godfrey, Miss Dorothy Webster, Mrs. W. Duckham, A. L. Stevens, Merstham Yellow, and Mrs. T. W. Pockett are all well represented in many fine examples.

AT REGENT'S PARK.

It is many years since these gardens were so bright in autumn as they are at the present time. Mr. E. F. Hawes, who has charge of the practical side of gardening here, has taken considerable pains to make the gardens and conservatories bright with Chrysanthemums. Big blooms are somewhat tabooed. Of the early-flowering Chrysanthemums 2,500 plants are cultivated, and in one large border there are quite 1,600 plants full of flowers. This is quite a new feature for displays in the open border in the heart of the metropolis, and proves that the Chrysanthemum is excellent

for town gardens. It may be well to mention a few of the more prominent Japanese sorts that do so well in this town garden. Beautiful, indeed, were the plants of Vice-President Hardy. This is a pretty free-flowering crimson and gold flower, developing charming sprays of dainty blossoms. White Quintus is a pure white that appears to do well. Orange Child is an old sort of an orange-yellow colour, and is a plant with a compact habit. M. Dupuis is another orange-coloured sort, making lovely sprays, and the habit is also good. Mme. Marie Masse, lilac-mauve, and its sports Crimson Masse, chestnut; Ralph Curtis, creamy-white; Rabbie Burns, cerise pink; and Horace Martin, a glorious yellow, are a quintet for early flowering that cannot be beaten. The plants are very branching, robust, and free. Mme. Casimir Perier, creamy white, tinted pink; and its recent sport Mrs. A. Willis, yellow, shaded and suffused red, are two excellent sorts for the outdoor garden, being free-flowering and most effective. Ivy Stark, orange yellow; Harvest Home, crimson and golden yellow; and Francois Veillermet, lilac-pink, are three popular sorts that never fail to do well outdoors, and on the occasion of our visit they were largely in evidence. As a matter of fact all the best Japanese and Pompon varieties are extensively grown. Novelties of the present season are not forgotten, and a big stock is already being worked up for next year's display. No less than four thousand decorative Chrysanthemums are grown in pots, and these comprise Japanese, single-flowered and other types of the Golden Flower. We were pleased to see a beautiful group of the variety Miss Mary Anderson. This and its yellow sport, Miss Annie Holden, are not possible to beat; they are free-flowering, and the plants are of excellent habit. Ladysmith is another very fine single, the colour is a pleasing shade of rose, and contrasted with the yellow disc is most effective. The plants are grown quite naturally, and make handsome bushes. One instance is particularly worthy of mention. A large stone vase, some 8 feet, more or less, in diameter, was planted with the last-mentioned variety, so that its free growth could be amply displayed. Overhanging the sides were beautiful fresh green growths of Asparagus Sprengeri. D. B. C.

AT BROCKWELL PARK.

THE little collection here is housed in the same place as heretofore. We had almost hoped that with all the advantages this southern park enjoys a new and suitable glass structure might have been provided, for the purpose of giving to the residents this year a floral display such as is to be found at the other London County Council parks. Within the narrow limits at his disposal, however, Mr. Curle makes the best use of the place that be possibly can. Most of the best of the Japanese varieties are grown, and among them are some capital blooms of Mme. Paolo Radaelli, N.C.S. Jubilee, Mrs. Coombes, Mme. C. Roissard, and Mrs. Bryant in the pink and rosy tints. Some good yellows and bronzes are Miss Mildred Ware Earl of Arran, Sensation, Mrs. A. H. Hall, Soleil d'Octobre, Kimberley, George Lawrence, and Admiral Avellan; beautiful blooms of Australie, Mrs. G. Mileham, Millicent Richardson, and Marquis Visconti Venosta in the purples are to be seen; while other excellent Japanese of varying tones are here and there represented by sorts like Mrs. Henry Weeks, a noble white of grand dimensions, big and solid in build; W. R. Church, Mme. Gustave Henry, Mrs. J. C. Cleve, the peculiar straw-coloured sport from Australia, Mrs. J. Shrimpton chestnut and gold, Surprise, and John Shrimpton; Descartes in the Anemone section is a fine flower of rich, deep vinous crimson, and in the hairy section the golden buff-coloured Hairy Wonder is at once conspicuous and of considerable decorative effect. The incurved section is represented by two highly coloured, well-known varieties to the visitors at the London parks, viz., Baron Hirsch, a fine shade of deep, rich golden chestnut; and Mr. R. Bahuant, a deeply built rosy purple flower of excellent form. Although the collection is small, and the conservatory ill-adapted in several ways for the purpose, an excellent display is made and the visitors are numerous.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THERE was a smaller display than usual at the meeting of the Royal Horticultural Society on Tuesday last. Orchids were the chief feature, although other plants and flowers were well shown too. A gold medal was given to the collection of Orchids shown by Jeremiah Colman, Esq., Gatton Park, Reigate. From Lord Aldenham's gardens at Elstree an extensive exhibit of cut shrubs was made: they served to draw attention to the subject of the lecture given in the afternoon by the Hon. Vicary Gibbs, viz., "Planting Woods for Winter Effect."

ORCHID COMMITTEE.

Present: Mr. J. Garney Fowler (chairman), Messrs. James O'Brien, de B. Crawshaw, Norman C. Cookson, J. Wilson Potter, W. Boxall, W. H. Young, F. W. Ashton, A. A. McBean, H. T. Pitt, H. A. Tracy, G. F. Moore, W. H. White, J. Charlesworth, H. Ballantine, Richard G. Thwaites, James Douglas, Francis Wellesley, Walter Cobb, and F. Sander.

The Orchids from Jeremiah Colman, Esq., Gatton Park, Reigate (gardener, Mr. W. P. Bound), filled one side of a long table. They were attractively arranged, plenty of greenery being interspersed. *Cattleya labiata* was, of course, conspicuous. There was a small group of it at each end of the table; *Lelia præstans* in several varieties, and very beautiful they were. L. p. George Prince of Wales and L. p. The Queen were two of the best. *Lelia præstans* Gatton Park variety is unique in its colouring: the sepals and petals are palest lilac-rose, the lip deep slaty blue, and with the yellow throat has a charming effect. Among other plants in this extensive exhibit we might mention *Cattleya aurea*, bearing splendid flowers; *Epidendrum ciliolare*, with its quaint greenish white blooms; *Cattleya howringiana* lilacina, *C. labiata* alba, C. I. Master J. Colman, C. I. cerulea, C. Minerva lilacina, L.-C. colmaniana, and other *Cattleyas*; *Cyperorchis affine*, with racemes of yellow tubular flowers; some very good hybrid *Cypripediums*, *Miltonia Regnelli* Gatton Park variety, and *Cymbidium tracyanum* were all well represented. Gold medal.

Messrs. Charlesworth and Co., Heaton, Bradford, Yorks, had many beautiful things in their group of Orchids. *Lelio-Cattleya callistoglossa* is a very handsome flower with pale rose-lilac sepals and petals and rich purple lip, and was well shown. *Vanda cœrulea*, too, was very beautiful. *Cattleya Mantinii*, *Brasso-Cattleya Mossie-digbyana*, *Cattleya Peetersii* (labeled *× hardyana*), *C. Germania* (scholfieldiana *× hardyana*), *Lelio-Cattleya Sunray* (L. cinnabarina *× C. auperba*), *C. Octave Doin* (Mendelii *× aurea*), and L.-C. *luminosa* (L. tenebrosa *× C. aurea*) were very fine among the hybrids. *Cattleya Doin* is particularly beautiful, the flowers of perfect form, the broad white petals tinged at the edges with lilac; the lip is purple at the base, with two rich yellow lobes above; the throat has a yellow ground, heavily lined with crimson-brown. Silver-gilt Flora medal.

The group of Orchids from J. Bradshaw, Esq., The Grange, Southgate (gardener, Mr. G. Whitelegge), included some very good *Cattleya Mantinii* (howringiana *× aurea*), *Cymbidium tracyanum*, *Cattleya labiata*, and some white varieties of the latter. These comprised C. I. Penelope, C. I. anesiana, C. I. R. I. Measures, C. I. G. G. Whitelegge, and C. I. Ariadne. *Lycaste Skinneri* alba, *Lelio-Cattleya luminosa*, and L.-C. *Ingramii* were also shown in this group. Silver-gilt Flora medal.

Cypripediums and *Cattleyas* predominated in the group shown by Messrs. Sander and Son, St. Albans. Of the former *C. cananthum superbum*, *C. Masterso-callosum*, *C. Swinburnei magnificum*, *C. insigne Olivine*, *C. arthurianum*, C. a. var. *pulchellum Harrisii*, *C. callosum Sanderi*, and *C. Stanley Rogerson* (Charlesworthii and *callosum*). *Cattleyas* comprised *C. labiata*, *C. Mantinii*, *C. johnsoniana*, and others. A splendid plant of *Cymbidium tracyanum*, *Zygopetalum Klahochochum superbum* (with white crimson-tipped petals and sepals), *Miltonia lubbersiana*, *Cycnoches chlorochilon* and *Calanthe oenata gigantea* were other interesting plants in this exhibit. Silver Flora medal.

Messrs. Hugh Low and Co., Bush Hill Park, Epsford, exhibited a splendid plant of *Cattleya labiata autumnalis*, carrying some twenty-three fine flowers in their group of Orchids. Of special interest were *C. labiata* (white var.), *C. Parthenia* Prince of Wales and *Brasso-Lelia Mrs. Gratrix*. *Warszewiczella walesiana* was well shown, and *Cypripedium Standard* (a good hybrid between *Charlesworthii* and *leeanum*), *Vanda kinaballiana* and *Ionopsis paniculata*, too, were very attractive. Silver Banksian medal.

Messrs. Stanley Ashton and Co., Southgate, N., exhibited a group of Orchids in variety that included some excellent *Cattleya labiata autumnalis*. *C. Mantinii inversa* was well shown, and so was *C. Loddigesii*. *Miltonia Cogniauxii*, said to be a natural hybrid between *M. moreliana* and *M. Regnelli* has purplish red sepals and petals, and a rose-purple lip marked with lines of a deeper shade. Among *Cypripediums* *C. insigne Balis* and *C. I. youngianum* were noticeable. Silver Banksian medal.

Messrs. J. and A. McBean, Cocksbridge, Sussex, showed some splendid *Cattleya Mantinii*, *Odontoglossum crispum*, and *Cypripedium insigne* varieties. *Cattleya labiata* was good, and so were *Cypripedium Nemaria Moensii*, *Dendrobium Dearii*, and *Cymbidium tracyanum*. Among the *Cypripedium* insigne varieties were C. I. Sanderi, C. I. Dulcotea, C. I. Harfield Hall, and *C. leeanum giganteum*. Silver Banksian medal.

H. S. Goodson, Esq., Fairlawn, West Hill, Putney (gardener, Mr. George E. Day), showed some excellent *Cattleya labiata* in several varieties, the white *Lycaste Skinneri*, *Maxillaria picta*, as well as several *Cypripediums*, including *C. spicerianum*, *Swinburnei arthurianum*, *Charlesworthii*, *lathamianum*, and others. Silver Banksian medal.

Among the Orchids from Messrs. James Veitch and Sons, Limited, Chelsea, were *Cattleya Mantinii*, C. Mrs. W. J. Whiteley, C. Fortia, *Lelio-Cattleya digbyana-gigas*, *Sophro-Cattleya Atreus*, L.-C. Decia, L.-C. Tenos (howringiana *× L.-C.*

Nysa), L.-C. *haroldiana*, and others. They made a beautiful display. Silver Banksian medal.

R. Briggs Bury, Esq., Bank House, Accrington, showed a few very beautiful Orchids. They included some lovely forms of *Cattleya labiata*, a splendid form of *Cypripedium triumphans*, *C. callosum Sanderi*, and *C. leeanum magnificum*. Silver Banksian medal.

A vote of thanks was given to the Hon. Walter Rothschild for a small group of Orchids.

A botanical certificate was awarded to *Liparis fulgens* sent from the Royal Botanic Gardens, Glasnevin, Dublin.

Cypripedium - The Pelican (*Sandero-superbiens × rothschildiana*) was shown by Norman C. Cookson, Esq.

NEW ORCHIDS.

Lelio-Cattleya Cyppei.—A very beautiful and richly coloured flower, the result of intercrossing *Lelia cinnabarina* and *Cattleya gigas*. The colour of the sepals and petals may perhaps be best described as orange-apricot, while the lip is plum-coloured and the throat yellow, a most beautiful flower that quite deserved the first-class certificate given to

ASPARAGUS MEDEOLOIDES MYRTIFOLIA.

it. Shown by Messrs. Charlesworth and Co., Heaton, Bradford, Yorks.

Lelio-Cattleya illustris.—A very pretty flower of somewhat stiff appearance. The petals are a charming colour, soft rose and buff, rose predominating in the sepals, the buff is most noticeable. The lip is intense bright purple. *Lelia Latona* and *Cattleya aurea* were the parents. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

Cattleya labiata Mrs. Francis Wellesley.—A very beautiful variety of *Cattleya labiata*, with rich rose-coloured sepals and petals and a wide open lip that is rose-coloured at the edge, marked with white almost throughout, and with yellow at the entrance to the throat. From F. Wellesley, Esq., Westfield, Woking. Award of merit.

Cattleya G. W. Low Scholfield.—*Cattleya* Lord Rothschild and C. Cookson are the parents of this hybrid, which has white sepals and petals. The lower half of the lip is purple, but the top of each lobe is much lighter and the yellow lines

from the throat run into it. From Messrs. Sander and Son, St. Albans. Award of merit.

Cattleya labiata Miss Kate Brazier.—This is a beautiful variety of *Cattleya labiata*. Petals and sepals are pure white, the white lip is veined and tinged in the centre with purple, and has a blotch of yellow at the entrance to the throat. The petals are very fine, large, and of perfect form. From Messrs. Sander and Son, St. Albans. Award of merit.

Lelio-Cattleya Eric Lucas.—*Cattleya Warneri* and *Brassavola digbyana* are the hybrids of this large and handsome flower. The large, loosely-arranged sepals and petals are rich rose, and the lip has a deeply fringed rose-coloured margin; the throat is green, fading to fawn towards the front of the lip. From C. J. Lucas, Esq., Warnham Court, Horsham. Award of merit.

Cypripedium × W. R. Lee.—This is a hybrid raised at Oakwood, Wylam-on-Tyne, by Mr. Norman C. Cookson (gardener, Mr. Chapman). It is a large, handsome flower, the dorsal sepal lined with dark crimson upon a creamy white ground; the long drooping petals are marked with deep crimson spots, and the large protruding lip is dull red and prettily veined. Award of merit.

FRUIT COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. S. Mortimer, Alex. Dean, H. Parr, G. Kelf, F. Q. Lane, G. Reynolds, J. Jacques, J. Willard, G. Norman, Owen Thoma, G. Wythes, W. Pompart, A. H. Pearson, Edwin Beckett, and J. Cheal.

Mr. Charles Ross, Welford Park Gardens, Newbury, exhibited a collection of seedling Apples, all of them raised by himself. They included Charles Ross and The Rival, of which we give illustrations elsewhere, Hector McDonald, Redwing, The Houblon, Paroquet, Atalanta, and others. Most of these have had a certificate or an award of merit at some time. A fuller account of them appears elsewhere in this issue. The Hogg Memorial medal was awarded.

Mr. H. King, Bedfordham, Bedford, exhibited a small collection of Apples and Pears. The former were finely coloured, and comprised Red Reinette, Malster, Schoolmaster, Hall Door, The Queen, Sandringham, Golden Noble, &c. Of Pears there were Beurré Superfin, Beurré Diel, Duchesse d'Angoulême and others. Silver Banksian medal.

A cultural commendation was given to Canon Ellacombe, Hinton Vicarage, near Bristol, for a dish of Persimmon fruits grown out of doors, we believe, although this was not stated. Mr. Edward Lane, Kynaston, Ross, Herefordshire, sent several seedling Apples, but no awards were made.

Mr. Strunell, Rood Ashton Gardens, Trowbridge, showed a large handsome conical Apple; Mr. Charles Ross sent Redwing (very highly coloured), and Lerks Pearmain; Mr. J. E. Hathaway, Baldersby Gardens, Thirsk, sent Apple Baldersby Elect; Mr. G. R. King showed Essex Pippin; and Messrs. James Veitch showed Apple H. Ballantine (Peasgood's Nonsuch *× St. Edmunds Pippin*). These and other seedling Apples were shown, but no awards were made.

Mr. G. R. King, East Hornden, Essex, showed Potato Reconnance (Champion of Scotland *× Beauty of Hebron*). Mr. King also sent Potato Hercules.

Filbert Nut Faulkner's Prolific was sent by Mr. A. Faulkner, Inkpen, Hungerford.

Apples Charles Ross and The Houblon were well shown by Messrs. Horne and Sons, Cliffe, Rochester. We give illustrations of these in THE GARDEN this week, together with descriptions.

The imperishable Lubrose Paint was shown from the Lubrose Paint Company, Moorgate Station Chambers, E.C., and Val's Beetlecut was also exhibited by the manufacturers.

Messrs. D. Dowel and Son, Ravenscourt Avenue, Hammer-smith, exhibited pots in various sizes. Included were special deep pots for Lilies, &c., Orchid pans, and 2-inch pots for seedling Orchids. The new wire crock, a substitute for the ordinary crock, was shown also.

FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), Messrs. C. T. Druery, H. E. May, James Walker, R. Dean, James Hudson, E. Molyneux, J. F. McLeod, G. Reuthe, J. A. Nix, R. Hooper Pearson, George Gordon, Charles Jeffries, Charles Dixon, H. J. Cutbush, J. T. Bennett-Poe, Charles E. Shea, William Cuthbertson, E. H. Jenkins, W. J. James, E. T. Cook, George Paul, and Edward Mawley.

Probably the most interesting exhibit, and important, too, in view of the lecture on shrubs for winter effect, before the floral committee, was the remarkable collection of cut shrubs from Lord Aldenham, Elstree. Some 175 species and varieties were shown. Even from the point of view of effect the arrangement was in every way excellent, giving ample evidence of the value of these things when grouped in garden, pleasure ground, or woodland. We have no intention of cataloguing the whole of the collection. It was fully representative, not only reflecting great credit as a whole, but testifying to the way in which the culture of these shrubs is encouraged at Elstree. Hollies, Cotoneasters, Privets, Osmanthus, *Colletia cruciata* in flower, *Ruscus aculeatus* in fruit, *Pyrus prunifolia* in fruit, *Arbutus Unedo* in flower, *Physalis Franchetti*, Ives. Heaths, *Euonymus europæus* in fine fruit, *Typha latifolia* (Bulrush), *Crataegus Crus-Galli splendens*, with large scarlet fruit, *Pyrus Malus John Downie*, *Berberis* in variety, *Salix babylonica annularis*, and *Quercus coccinea* Waterer's variety were among the more conspicuous. Silver-gilt Flora medal.

Messrs. William Cutbush and Sons, Highgate, staged a very attractive lot of hardy flowers, in which Michaelmas Daisies, *Chrysanthemums* in great variety, *Gladioli*, herbaceous *Lobelias*, *Erigeron speciosus*, *Rudbeckia laciniata*, *Anemone Queen Charles*, lot very fine; *Polygonum amplexicaule*, reddish rose spikes; *Engenia Ugii*, a Chilean evergreen shrub in fruit; *Colchicum*, *Shortia galacifolia*, and *Galax aphylla* in plenty were contained. A large collection of Tree Carnations was shown. Silver Flora medal.

Winter-flushing Carnations in variety from Messrs. Low and Co., Bush Hill Park, included Mrs. Lawson, Royalty, Floriana, and others, the same firm exhibiting *Asparagus medeoloides myrtifolia*.

THE GARDEN

No. 1721.—Vol. LXVI.

NOVEMBER 12, 1904.

LESSONS FROM A FRUITFUL YEAR.

IN her provision of the common fruits of the earth Nature has been very bountiful this year, and with here and there an exception orchards and fruit gardens have returned a full harvest, yet in the midst of the abundance one hears numerous complaints, not of the fruit or its quality, but of the smallness of its monetary value and the difficulty of being able to dispose of it at a profit. It has been pitiable during the past month or two to see Apples in orchards some distance from market centres, that were well deserving of a better fate, falling to the ground and remaining there to rot. We have asked growers to give a reason for this deplorable waste, and have been met with the one general answer that the Apples would not pay to pick because there was no one to buy them. In ordinary seasons dealers pay visits to these outlying homesteads and buy the fruit from the growers, but this year the latter have waited for the purchasers in vain, because they could get more fruit than they could deal with at their own doors and had no need to go in search of it. Enterprising up-to-date growers, of course, seek out their own markets, but the fact remains that many of the people who contribute in both small and large ways towards the Apple supply of this country still adhere to the methods of disposal which were in vogue in the days when fruit culture was not the important industry it is now, and when foreign competition was unknown.

If we were apt scholars we might learn forcible lessons from these heavy fruit years, and how much behind we are in the way of varieties. There is far too much rubbish grown and put on the markets, particularly in the way of Apples. And though there is some truth in the statement that the best always sells in spite of the inferior, it is nevertheless a fact that when a market is glutted with low class produce its tone is brought down and the value of highly superior fruit is reduced in consequence. Various movements have been put on foot from time to time to encourage the culture of only the best varieties of Apples, and in certain districts good results are being shown, but there are hundreds and thousands of trees which existed before any agitation began that still stand and bear, and many of them are of varieties that will not pass muster in present-day competition. Perhaps matters will right themselves in time, but the process

is slow, for though any man who plants an Apple tree now may be given credit for obtaining a good variety if possible, there will be no radical changes, for a peculiar sentiment seems to protect old trees. So long as they grow and bear they are allowed to stand, the natural consequence being that so long as Nature keeps life in the relics of old-time Apple culture, scrubby fruits of inferior varieties will continue to find their way into the markets and do something towards keeping down the value of better produce. Again, it must be remembered that fruit of the best varieties in the hands of a good cultivator is a different article from that produced by a man who pays little or no heed to his trees. It is a significant fact that in years of plenty like the present the individuals who complain the least about low prices are reputedly good growers, while the fact remains that good cultivation may pay, but bad cultivation certainly will not.

Another lesson taught by the abundant harvest was referred to in a recent leading article in *THE GARDEN*, where it was predicted that, notwithstanding the unusually good crops this year, fruit from abroad will be as much in demand as ever after Christmas. In other words, we want better and more systematic methods of storing Apples instead of selling early, midseason, and late varieties direct from the trees, and bringing about the unavoidable gluts on the markets. Quite recently we read an article advising cold storage of Apples as a means of avoiding gluts and spreading the supply over a long period, but while we have many varieties that will keep almost till Apples come again if carefully stored, all that is needed is to grow a greater proportion of such, and then take care of them till the demand arises, after they are removed from the trees. Taking a broad view of the matter, it is a shame to see Apples like Blenheim Orange and Bramley's Seedling offered for sale in October when there are varieties in season then which would not keep much longer, simply going begging to find customers.

Lastly, we are once more brought face to face with the shortcomings of our methods of distribution. Enquiries are made, commissions sit, associations argue, and railway companies are abused, but the solving of the difficulty seems as far off as ever, and, except in a matter of miles, there are greater obstacles between British producers and consumers than those which divide the latter and growers in the colonies and abroad. A general custom is to lay it all to heavy railway rates and preferential

tariffs, but the companies vainly endeavour to point out that they do not live as philanthropic institutions, and shareholders know that dividends have been by no means high of late. Within a certain area of any large market centre distributive difficulties may not be great, but when one gets outside that they become apparent, and people ask what is the good of growing fruit when there is no market to take it, yet in a great town, perhaps, less than a hundred miles away, there are plenty of people ready to buy if they could only get the fruit at a reasonable price. Only the other day we paid threepence for two Apples (a pound) in a shop in a town situated in the heart of a fruit-growing district, and yet we know of growers only a few miles away who would gladly have given six times as many for the same money. There are obviously a good many pickings to be had out of the pie, because it is quite certain that in a season like the present the consumer does not reap the advantage of the cheap rates at which producers sell fruit. In fact, of all the questions raised in connexion with fruit culture that of distribution is the most complex.

HARDY CHRYSANTHEMUMS

ONE cannot be long in a garden at this time of year without learning that the hardy Chrysanthemum is chiefly responsible for its attractiveness. This delightful flower braves the keenest winds, the coldest rains, and some degrees of frost with apparent indifference. Without it we should hardly be tempted to linger in the garden at all, for it is the only flower now left to us. The hardy Chrysanthemum is everybody's plant; it yields a profusion of flowers with very little trouble—the maximum of result in response to the minimum of care—and it increases in decorative value for several years.

There is now an almost endless number of varieties to choose from in colours indescribable, white, and shades of pink, yellow, orange, bronze, red, and crimson; a careful choice of sorts will ensure a bountiful harvest of beautiful flowers. It is questionable whether any other hardy plant gives such a rich gathering of blossoms as the hardy Chrysanthemum. Who at this dull season would be without the lovely bunches of Goacher's Crimson, Horace Martin, Marie Masse, and others among the larger-flowered sorts, and the miniature bushes of Pompons, which now are as full of flower as the Hawthorn is of haws? For all are most easily grown.

Those who know the value of the hardy Chrysanthemum in the garden and in the home must have remarked, and regretted also,

its absence from the wonderful exhibition held at the Crystal Palace recently. This was given up almost entirely to the huge blooms of the Japanese sorts and the much less beautiful "incurves," both, no doubt, of value, but nevertheless appealing to a comparatively small section of the public in comparison with the popularity of the hardy varieties. In the National Chrysanthemum Society's show all types of the flower ought to be adequately represented, and it hardly seems fair that the most important one from the point of view of the amateur—and, perhaps, we might add of the professional gardener—should be relegated to such obscurity as practically to be excluded. If this type of the Chrysanthemum were encouraged by the society at its exhibitions we feel sure that many classes of general interest and usefulness would be added.

Why does not someone try to get scent into these flowers? We remember an old purple variety called Progne, said to have a strong Violet-like fragrance; although we would not care unreservedly to endorse this statement, it undoubtedly is pleasantly scented. The fragrance is quite distinct from that of the ordinary Chrysanthemum, which, by the by, we do not think at all disagreeable. We heard recently of another variety said to be sweetly scented, but we do not remember the name. Thus there would seem to be a basis for hybridists to work upon. It would be interesting to have a list of sorts that possess a distinct fragrance, and perhaps readers who may happen to know of any will be good enough to send us the names.

Why have the single Chrysanthemums fallen into disrepute? With the exception of the beautiful variety Mary Anderson, which, however, is more often grown in pots under glass than out of doors, they are poorly represented in the outdoor garden, yet their aid in the home when cut is invaluable.

LILIES IN 1904.

BEFORE attempting any detailed account of the doings of my own Lilies this year, I should like to call attention to two most important and interesting notes which have recently appeared in *THE GARDEN*.

In the number for August 27 (page 134), "A. O." describes the marvellous success of Mr. Corrin in flowering

L. SULPHUREUM in a small front garden at Richmond, and in the number for October 1 (page 229) a photograph was reproduced showing the plants in bloom near the house. It seems that five years ago Mr. Corrin planted seven of the bulbils which this Lily, like *L. tigrinum*, produces freely in the axils of its leaves, in his ordinary garden soil, to which a little lime rubbish, sand, and fowl manure had been added. These grew and steadily improved, two or three of them producing flowers in the fourth year, and all seven doing so this (the fifth) year; the flower-stems were nearly 6 feet high, six of them with three blooms, the seventh with one.

This is, indeed, good news to many, if not all, Lily growers, and most encouraging to those who have hitherto been somewhat doubtful as to the hardiness of this grand species in our ordinary English climate. If it will flourish like this in a simple compost at Richmond, it should prove to be a thoroughly hardy and satisfactory Lily, one that may be confidently added to the small and select list of "reliables," and we should all try our luck with it as soon as possible. It is likely that we shall succeed better with the bulbils than with the bulbs

themselves, though we may have to wait four years, or even five, before we get any flowers, for these home-grown bulbils will be certainly obtainable, and will develop into bulbs in due course, which are better adapted to our climate than imported ones.

I have quite a number from my own two bulbs, and they are making good growth; but I put them originally in pans in a cold frame, not liking to trust them in the open ground. They will now, however, be planted out this autumn in a suitable soil and position, and I shall hope to live long enough to admire the fine effect of a big clump in flower, say in 1908!

LILIUM TESTACEUM.—In a letter to *THE GARDEN* of September 17 (page 197), Mrs. Carroll writes from Bickley Vicarage, Kent, to say that five years ago she was collecting plants on a hill above Ragatz, in Switzerland, and came upon some unknown Lilies then bearing seed-pods. She brought home some bulbs and planted them in sandy, stony soil in her Kentish garden; the third year they flowered, unmistakably *L. testaceum*! It seems impossible that there can have been any mistake, and it is indeed a startling discovery, and one that will cause much perturbation among the Lily "scientists," for *L. testaceum* (or *excelsum*), the well-known and popular "nankeen-coloured" Lily, has always been considered a hybrid, most probably between *L. candidum* and *L. chalcidicum*, and has never been found in a wild state before. It is rather extraordinary that Mrs. Carroll's letter has elicited no further correspondence on this interesting discovery, at least I have failed to come across any allusions to it since it appeared. Of course, it is possible that the bulbs brought home were, by some remote chance, stragglers from a distant garden, but this seems most unlikely. We shall, doubtless, hear more of these wild testaceums before long.

Now for a few remarks on the season of 1904 in my own small garden. I only wish I had something satisfactory to record, though I must say I hardly expected success with my Lilies after the lamentably cold and wet summer and autumn of 1903. It was a terrible handicap for the poor bulbs, and many of them failed miserably in consequence. In fact, I can count those species that have flowered well on the fingers of my two hands! Let me take them in order of merit, omitting those newly planted last autumn, and including only the old-established bulbs. First and foremost comes

L. HANSONI, which was simply marvellous! From my two bulbs, which did very fairly last year, I had this summer five spikes, four of which carried eleven, eleven, fourteen, and fifteen flowers respectively, while the fifth was a massive fasciated structure bearing a huge flattened-out head, like Hercules' club, with no less than fifty-nine blooms on it, all perfect. I have never seen such a head on any Lily before! A photograph of it was reproduced in *THE GARDEN* for August 13 (page 112). *Hansonii* is undoubtedly a most satisfactory Lily to grow, and apparently appreciates its quarters in my garden, on the west side of a big sheltering Holly bush, though it must have almost too much *Anemone japonica* all round it.

L. HENRYI, as usual, was splendid, better than ever, though to my mind it has two rather serious drawbacks—the somewhat straggling growth of its long curving stems and the comparatively small size of its flowers. But it is everybody's Lily, especially now it is becoming much cheaper, and it possesses a fine constitution, and will grow in almost any soil and position; moreover, we can get over

the difficulty caused by its peculiar growth by planting it among tallish shrubs, through and over which it will delight to climb and to arch its long powerful shoots, as it does in its own native land.

L. CANDIDUM came in a good third, and was very beautiful, several spikes bearing over a dozen, one as many as sixteen, flowers. But I very nearly had to leave it out of my well-beloved list of "V. G.'s" altogether, for at the critical moment, just as the buds were beginning to swell, that foul disease, *Botrytis*, made its appearance in nearly the whole of the clumps in the garden, and I was in despair. Thinking I might do something with liver of sulphur (potassium sulphide), I procured some without delay, and watered every part of every Lily, whether already affected or not, freely with a solution of 1oz. to 2½ gallons of water. The effect was simply magical; the disease was at once checked, if not altogether cured, and my grateful Madonnas a few days later were glorious in their wealth of divine flowers. I may add that I carefully removed and burned all the shrivelled leaves from the stems before watering, also that I gave a second dose to the most sickly-looking two days later. One or two of the expanded flowers eventually showed a suspiciously untidy brown edging to their petals, but had it not been for the bare stems it would have been a hard matter to discover that there had been anything amiss. Of course, it remains to be seen if the cure is permanent or only temporary, but in any case it is a great thing to know that the candidums can be saved at the eleventh hour by such a simple process.

G. S. REID.

(To be continued.)

RECENT PLANT PORTRAITS.

The first number of the *Revue Horticole* for October contains a portrait of

Callicoma serratifolia, a most interesting and apparently free-blooming flowering shrub from Australia and New South Wales. The bunches of flowers might be said to resemble a pale form of the well-known *Buddleia globosa*. It is by no means new, having been figured by Andrews in his "Botanical Repository" as far back as 1809, and also by Loddiges in the twelfth volume of his "Botanical Cabinet." Messrs. Nabonnand of Golfe Juan, near Cannes, hope to be able to supply rooted layers of this pretty shrub next spring. Though doubtless not quite hardy everywhere, it would probably be so in Devon, Cornwall, and the Isle of Wight.

The November number of the *Botanical Magazine* contains portraits of

Albium alhopilosum.—Native of Southern Turkestan. This is the largest flowered species of the genus, but is somewhat dull in colour and more botanically than horticulturally interesting. The white hairs on the foliage account for its specific name.

Helipterum splendidum.—Native of Western Australia. This is quite one of the most beautiful and showy of the composite everlastings that has yet been seen. It is in the way of the well-known *Rhodanthe Manglesii*, but its flowers are about three times larger, and of a yellowish creamy white. It is, unfortunately, an annual, and the plants of it that flowered at Kew in April of this year under unfavourable conditions as to sunlight produced no seed, and died after flowering.

Cryptostegia madagascariensis.—Native of Madagascar. This is a very beautiful stove flowering shrub, with large flowers of two shades of rose colour, resembling those of an Oleander.

Dendrobium bellatulum.—Native of China. This is a most distinct and beautiful little Orchid, with pure white flowers which have a broad vermilion lip, the two colours affording a most charming contrast.

Iris bismarckiana.—Native of Palestine. This is a very distinct and handsome Iris, introduced

from Lebanon in 1888 by Messrs. Dammann of Naples. It belongs, unfortunately, to the *Oncocyclus* or Cushion section of the genus, which few, if any, growers can cultivate successfully. The plant figured flowered in the Alpine house at Kew in May, 1904.

The *Revue de l'Horticulture Belge* for November figures

Davidsonia pruriens.—An exceedingly handsome stove shrub introduced by the late Mr. Bull in 1875, but which, from the amount of room it requires for its successful cultivation, is almost impossible to grow, save for those possessing warm houses like the Palm stove at Kew.

Bulbophyllum barbigerum, the curious little Orchid with its movable lip, which attracts so much attention when exhibited in public, though its flowers are otherwise quite insignificant.

W. E. GUMBLETON.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT WARREN HOUSE, STANMORE.

CHRYSANTHEMUMS are grown extensively in this garden, and both exhibition and decorative varieties are well cared for. Fully 1,000 of the former and about 2,000 of the latter are cultivated, and on the occasion of our visit the exhibition plants were at their best. Mr. C. J. Ellis, who has charge of these gardens, has certainly just claim to be recognised as a successful grower of large blooms. He has got together a representative collection of Japanese sorts. This grower has seen the fallacy of retaining the older kinds for exhibition, however pleasing and attractive they may be. Unless one has the largest and the best, not necessarily the coarsest and least attractive because they are big, an exhibitor has little chance of succeeding. One of the groups in this collection is set up in a large glass house. Here the plants have plenty of room, and the excellent system of ventilation ensures their well being. Mrs. Bischoffsheim takes a keen personal interest in all that concerns the garden. The sport from the popular Miss Lily Mountford, that originated here, is named after her.

For effective use in the conservatory this is a beautiful variety, hardly large enough for exhibition perhaps, but distinctly pleasing owing to its crimson-scarlet and yellow colouring. The blooms of Mrs. George Mileham were very large, the bright rose-pink colour, with silvery white reverse, making this a standard Japanese sort. Better blooms than those of the bright amber-coloured Mrs. Harry Emmerton are seldom seen. The handsome butter-yellow coloured blooms of Mrs. Greenfield were attractive, as were also those of Mr. F. S. Vallis. The last named is an ideal exhibition flower, having florets of very great length, building up a large and handsome bloom; colour, soft citron-yellow. This is a plant of easy culture. The large white incurved Japanese blooms of Miss Elsie Fulton proved that this fine sort still maintains its high position as an exhibition flower. Mme. Herrewége, a pure white sport from Australie, the deep rose, with silvery reverse, incurved Japanese, was all that one could desire, and the blooms of the parent variety were quite up to the usual standard. General Hutton is another handsome bloom; the flowers deep golden-yellow, tinted with red. The intense orange-yellow flowers of Duchess of Sutherland were noticeable, owing both to their colour and their elegant and graceful form. This is a beautiful flower of which we unfortunately have too few.

The newer Miss Mildred Ware, a bronzy carise bloom of drooping form, is largely grown here. Henry Perkins, introduced two seasons since, again showed its splendid exhibition qualities; it is reddish crimson on deep yellow ground. Bessie Godfrey is a canary-yellow Japanese bloom of spreading and drooping form, and we have seldom seen the blooms of George Lawrence (gold and bronze) in better condition. The white flowers of Mme. C. Nagelmakers, Simplicity, and Mutual

Friend much impressed us with their good quality. Richer coloured flowers were represented by Godfrey's Pride, Mrs. R. Darby, and many others, and of the flowers of Lord Ludlow a special note must be made. Quite 2,000 plants of the decorative sorts are grown in bush form, and these make a fine display, extending from October till March. Such varieties as Soleil d'Octobre begin the season well, and with Souvenir de Petite Amie, L. Canning, W. H. Lincoln, Mme. Felix Perrin, and quite a host of others provide an abundance of cut flowers for indoor decorations.

D. B. C.

NOVELTIES AT THE CRYSTAL PALACE.

WE do not generally expect to see the season's new introductions at the shows. As a rule, the majority of them are first seen at the trade growers, and then in the following and subsequent years, if they meet with public approval, they gradually find their way to the showboards of the leading exhibitors.

At the National Chrysanthemum show held at the Crystal Palace recently there was a large number of novelties displayed, and of these the following appear to be the most promising: Souvenir de Mme. Baron, a fine pale sulphur-yellow sport from Miss Elsie Fulton; Roi d'Italie, one of Calvat's new seedlings, a grand incurving bloom with whorled florets grooved and pointed at the tips, colour rich deep yellow; W. A. Etherington, blooms of the pure Japanese type, very large in size, with very great length of floret, colour lilac-mauve, passing to white; Beauty of Leigh, a fine Japanese with florets curly at the tips, colour a fine shade of silky glossy yellow; G. F. Evans, very full and double, florets rather pointed, big blooms, incurved type, pointed at the tips, rich golden amber; Emlène Poitevine, an incurved form, very close and compact in build, and slightly hairy, large, colour deep golden-yellow; Chrysanthémiste Montigny, an immense Japanese, grooved florets and twisted, pure pale primrose yellow; Lieutenant-Colonel Dacroiset, a large yellow Japanese with very long florets; Mrs. E. Crossley, big Japanese with broad florets, pure, pale butter yellow; Mrs. Boosey, another Japanese of good size, with broad florets, a globular flower, colour rosy mauve, reverse silvery; Mrs. Charles Beckett, a large white; Buttercup, a large solid-looking incurved of rich decided yellow, deep and solid in build; and Mrs. A. H. Loe, a very fine deep-coloured crimson, a large Japanese, with golden reverse, one of the novelties that was certificated should also be mentioned.

C. H. P.

CHRYSANTHEMUMS AT BATTERSEA PARK.

THE exhibition of Chrysanthemums which is annually held in the large greenhouse in the frame ground near the Albert Bridge Road entrance is one of the most attractive of its kind in the metropolis. A large span-roofed house, about 110 feet by 21 feet, is devoted to the display, which is set up in the form of a large sloping bank of bloom, interspersed with a few foliage plants at intervals, the sides and ends of the house being covered with pretty little freely-flowered plants of decorative Japanese and Pompon varieties in great profusion.

All kinds of standard varieties in the various sections are shown, from that tiny little gem Mlle. Elise Jordan to the most gigantic of the modern Japanese, and the taste displayed in the arrangement as a whole leaves little or nothing to be desired. Among the hairy varieties now but little esteemed by the general body of growers for show, but which still attract a little curiosity on the part of the general public, are S. T. Taggart, a pure canary yellow; Leocadie Gentils, a pretty pale lemon yellow-coloured variety of good size; and the well-known and almost ubiquitous Hairy Wonder and Beauty of Truro.

Another section always represented at Battersea is the large-flowered Anemone group, and instances of these that are in good form are the well-known Descartes, a fine variety of great size; and of a rich

shade of deep vinous crimson; Delaware, an old American variety of nice character; W. W. Astor, and Sir W. Raleigh. The incurved section is also very well done, and there are numerous examples of this old-fashioned type in many of its best forms. Among them are most if not all of the Queen family, the old purple Prince of Wales, Bonnie Dundee, Baron Hirsch, a fine golden-bronze variety, much esteemed in the London parks; Jeanne d'Arc, a very pretty pale blush well-formed flower of at least twenty years standing; Globe d'Or and Mr. Bunn in deep rich yellow, and Duke of Wellington, a noble solid-looking bloom of more modern build.

Japanese are, of course, in the ascendant here as elsewhere. Among them in the yellows are some really noble flowers, the chief in this shade being Bessie Godfrey, which is really a lovely pure pale yellow variety; Mrs. Harry Emmerton, large in size and of fine form; Earl of Arran, R. Hooper Pearson, quite a deep rich golden shade of this colour; Mrs. Greenfield, F. S. Vallis, and Mrs. T. W. Pockett.

All the well-known varieties of established repute are included in the Battersea collection. In the whites are Mme. Herrewége, the huge sport from its equally huge parent Australie; Souvenir de Petite Amie, dwarf and useful for the front row of such a bank of bloom as is here put up; Florence Molyneux, gigantic in size, tall of habit, and a fine effective flower for the rear; Mme. Gustave Henry, Miss Alice Byron, Mermaid, Lady Byron, Nellie Pockett, &c.

President Borrel is a remarkably rich variety, colour rosy magenta with golden reverse; then by way of curious and effective contrast is Mme. E. Roger, which in its young state is very distinctly green and excites much interest; John Shrimpton, William Seward, W. R. Church, and Eastman Belle are good examples in varying shades of crimson. Pretty varieties of pinkish tints are the old American variety Wm. Tricker, N.C.S. Jubilee, one of Calvat's best; l'Ami Etienne, Mme. A. Rousseau, Louise, and Mrs. Coombes.

C. H. P.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

November 15.—Royal Horticultural Society, 1 p.m. Horticultural Club Monthly House Dinner, 6 p.m.; Professor Boulger on "Gilbert White and the Selborne Society."

November 16.—Liverpool Horticultural Association Chrysanthemum and Fruit Show (two days).

November 17 and 18.—Grimsby Chrysanthemum and Fruit Society.

Royal Horticultural Society.—At the general meeting of Fellows held on the 1st inst., Mr. George Banyard, V.M.H., in the chair, thirty new Fellows, including Lord Bulcarres, Lady Harlech, Lady Hillington, the Hon. Florence Russell, Dr. Robert Bell, General Berkeley, Colonel Carr-Calthrop, Miss Lankester, and Miss Spring-Rice, were elected, and three other horticultural societies, of Oxford, Wylam-on-Tyne, and New Zealand, were affiliated to the parent society. The following are the dates fixed for the meetings of this society during 1905: January 3, 24; February 14, 28; March 14, 28; and March 30—April 1 (second Colonial fruit and vegetable show); April 11, 25; May 9, 23; May 30—June 1 (Temple); June 29; July 4, 18; August 1, 15, 29; September 12, 26; October 10—12 (British fruit); October 24; November 7, 21; and December 5 and 19. The dates of the Auricula, Carnation, Tulip, autumn Rose, and autumn vegetable shows are not yet decided. The first Colonial fruit and vegetable show, with British, Colonial, and foreign jam and bottled and preserved fruits, will take place on December 13 and 14 next. The society has been awarded a Grand Prize by the International Jury at the St. Louis Exhibition for their exhibit of copies of the Society's Journal in Group 105.

A golden wedding.—On the occasion of the celebration of their golden wedding Mr. and Mrs. A. Dean, Kingston-on-Thames, were invited to a

entertainment at St. James's Hall on the 4th inst. It proved to be a most pleasant and successful gathering. The hall was well filled with friends and well wishers, many of them from a long distance. The programme, which consisted of animated pictures, songs, and solos, was thoroughly enjoyed by all. Happily, speeches formed no part of the programme. Mr. Dean and his son simply said a few words of thanks for the kind expressions of good wishes from those present and from many absent friends. Before commencing the second part of the programme the president of the Temperance Association of Kingston availed himself of this happy occasion to present Mr. Dean with a beautifully illuminated address as some slight acknowledgment of the long and generous services he had rendered to the society. The meeting ended as bright and happily as it began, by a dance, in which all the younger and some of the older friends joined.

Gardening on the West Coast of Scotland.—Mr. Peter Barr, V.M.H. sends the following interesting letter from Kilm: "I have, the three months I have been down here with my sister, done little else than work in the garden. The last fourteen years Narcissus

planted in the same manner, close to the long border under the Ivy wall, and with grass in the same way, as these will remain as permanent margins to the beds and border. To see whether this class of Tulip will stand such treatment, last year I planted close to the foundation of the house Ixias, Sparaxis, Tritonias, and Babianas. Over these I planted Daisies. I was too late this year in coming here, and all were out of flower except the Ixias, and the flowers of these were as good as any I have seen under the most favoured conditions in Guernsey and Holland, and, for that part, in my own Cape pits long ago. The aspect is due east. This year I have planted around the greenhouse, close to the foundation, the same class of bulbs, and others with a west and south aspect, and expect better results. I am also planting, under similar conditions, some of the dwarf Daffodils, such as *N. minimus*, *N. triandrus*, &c. I shall spend the winter here, and expect a great floral display. The other day I added 120 species and varieties of herbaceous plants to those already in the garden, also a great variety of bulbs, to see what will succeed along the West Coast of Scotland. I had a great effect in October with the varied coloured foliage

us, and when walking near Hunter's Pier we were struck with a glorious sight. In a small garden there was a boulder completely covered with *Polygonum vacinifolium* in full flower."

The British Gardeners' Association in the North.—A meeting to consider the formation of a district branch of the British Gardeners' Association, was held on the 2nd inst. at the Station Café, Sunderland. The meeting was addressed by Mr. W. Hall, general superintendent of the Sunderland Parks, &c., as an official representative of the association. Mr. Hall's activity on behalf of this endeavour to raise the status of the gardener deserves much praise. After a short discussion it was unanimously resolved to form a Sunderland branch of the association, and as a result of the meeting the names of thirty-two additional local gardeners and nurserymen wishing to become members have been forwarded to the secretary. Similar meetings will shortly be held in the North, at Bradford (on the 17th inst.), Newcastle, and West Hartlepool, and in the South, at Bournemouth (on the 15th inst.), Croydon, and Caterham.

Royal Gardeners' Orphan Fund.—The seventeenth annual dinner of this fund has been arranged to take place at the Hotel Cecil, Strand, W.C., on Thursday, May 11, 1905, upon which occasion the Right Hon. the Earl of Mansfield has kindly consented to preside.

Apple Cornish Aromatic.—Among the many Apples that nowadays one rarely sees mentioned is Cornish Aromatic. It is an Apple that deserves a better fate than to be lost sight of. Dr. Hogg described it as "a valuable dessert Apple of first-rate quality; in use from October to Christmas. The tree is a free grower and an excellent bearer." A note from a correspondent some time ago thus refers to this variety, and we can endorse his opinion: "This variety is not so well known as it deserves to be. The fruit develops to a large size under good conditions and is very handsome and showy, in some instances being mistaken for a Peach when grown on a wall, owing to its rich colour. The flesh is firm and juicy, aromatic, and of good flavour. It does well in a sheltered position, and grows best as a bush or horizontally-trained or fan-shaped wall tree." Now that attention is directed towards

APPLE CORNISH AROMATIC. (Natural size.)

Johnstoni Queen of Spain has been naturalised in the grass. The last two years there has been a falling off in the number of flowers, so I lifted all the bulbs and found that the Narcissus fly had attacked them. I destroyed all the affected plants, and I thought I would make a little change in the arrangement. The garden has a long border backed with an Ivy-covered wall. On the lawn there is a large oval bed filled with Roses, &c., and on each side half-moon beds full of bulbs and herbaceous plants. I peeled off the turf round the half-moon beds and planted Narcissus Queen of Spain and *Galanthus Elwesii*, and sowed the surface with very fine dwarf-growing grass seeds. This was done in August. The grass is very pretty, especially when each blade is seen in the morning with "its ain drap o' dew" looking like diamonds glistening in the sun. In October there came to me six dozen mixed early single Tulips. These I planted round the oval bed alternated with Queen of Spain Daffodils, and sowed over with the same very fine dwarf grasses. These are just making an appearance. Being, I suppose, in luck's way, another six dozen early single Tulips and a package of Queen of Spain Daffodils came to hand. These I

of *Azalea ponticum*, and recently I have planted two round beds, 5 feet in diameter, with *Azalea mollis*, *Olearia Haastii*, *Berberis ilicifolia*, *Kalmia glauca*, *Andromeda axillaris*, *Pernettya mucronata*, *Buxus Fortunei variegata*, and *Deutzia gracilis*, edging the beds with single Wallflowers and planting *Rumex* amongst the dwarf shrubs. Not being sure they will succeed, I am having some *Auromone fulgens*, which I am sure will not fail me. Another little garden I have made at the north end of the house edged with "Nancy Pretty" and *Aralis lucida variegata*; in the centre a large *Olearia Haastii*, with *Rhododendron nobleanum*, *Hydrangea paniculata*, *Phormium tenax*, *Aucuba*, Lilies, &c. You see, I am likely to have plenty of occupation, if only in keeping the weeds down, as the garden for many years has suffered neglect. Double white Primroses have been a great sight in this garden during the past six weeks."

Polygonum vacinifolium at Kilm. Mr. Peter Barr writes from Kilm, Scotland, on the 4th inst. about this pretty plant: "Ten days ago we had Mr. Whitton (Superintendent of the Glasgow Parks) and Mrs. Whitton staying with

so many new varieties, some of the old and good ones are in danger of being lost sight of. Our illustration is from a photograph taken in the Langley nursery of Messrs. James Veitch.

Pears Le Lectier and Charles Ernest.—I was very much astonished, on reading the notes on these Pears in your issue of the 5th inst., to find that Messrs. Veitch are credited with having raised both of them. Le Lectier was raised by M. Auguste Lesneur of Orleans, by crossing the well-known Williams' Bon Chrétien and Bergamotte Fortunee, a stewing variety, and was first put into commerce by M.M. Transon frères of Orleans. Charles Ernest was raised by the well-known French firm of fruit growers, M.M. Baltet frères, Troyes, and put into commerce by them. I think it is only fair to the raisers of two such useful Pears that come in late in the season that the above correction should be made.—J.E.T.T.I.A. FIAT.

Chrysanthemum Lemon Queen.—For October flowering in the open this Chrysanthemum is especially good. In growth it is all that is desirable, reaching 3 feet, branching abundantly, and giving its bronzy yellow flowers freely.—E. M.

Early-flowering Chrysanthemum Freedom.—As its name implies this is a very free flowering plant. The colour is a pretty shade of rosy purple, and although not popular, it has its place in the hardy border, and may be used most effectively. Among the many novelties of this colour, the variety under notice stands out distinct from all others, and on this account a special value has been set upon the variety. It is in flower during October. The habit of the plant is excellent. When propagated in March and grown on steadily afterwards the best results are obtained.—D. B. C.

Early-flowering Pompon Chrysanthemum Veuve Clicquot.—This is a Pompon belonging to the early flowering section of which too little is known, and yet it is one of the best of the whole series. Unlike many of the Pompon sorts that are somewhat compact in growth, this plant is very free. The sprays stand out well from one another. Half a dozen plants arranged in a group in the outdoor garden are effective. For cutting they are always reliable, the blooms developing in good form without disbudding. The colour may be described as bronzy terra-cotta. In flower from late September till the end of October. Height about 2½ feet.—D. B. CRANE.

Vitis Colnetiae (autumn tints).—This has been three years on my house wall (west), and was this year a gorgeous sight. The larger leaves, up to 8 inches and 9 inches across in some cases, were brilliant red in shades, and this year's growth, which hung down, was deep purple at the tips. It retained both lovely tints some three weeks, owing to absence of frost and rain. In the summer the deep green leaves, of a leathery substance, are likewise beautiful. It runs about 20 feet up the wall, to which the old wood is lightly nailed. Of course, a severe winter might kill it, but so it would much else.—J. R. D., *Reigate*.

Chrysanthemum Ralph Curtis.—This sport, from Mme. Marie Masse, is a very useful variety flowering at the present time. It is creamy white in colour, with a purple shade at the base of the florets, height about 2 feet. Many of the early Chrysanthemums may well take the place of Sweet Williams, Canterbury Bells, &c., in beds and borders. If planted in the reserve garden till required, given a good soaking of water the day before lifting, transferred with a good ball of soil, and watered several times if the weather is dry, they will be little the worse for the moving.—A. OSBORN.

Rose Dorothy Perkins from cuttings.—Among climbing Roses this variety bids fair to eclipse any of the rambling section at present in commerce. The flowers are double, of a lovely soft rosy pink colour, and produced in clusters abundantly. The foliage is of a bright glossy green. Here it is grown on pergolas. Some of the growths have attained the length of 14 feet in two years. Its flowering season is remarkably long, blooming as it does from July to October, and still there are buds to open, which will last well into November should fair weather prevail. Having taken some of the old flowering wood out during February of the present year, and not feeling inclined to destroy the prunings, despite the time of year, I made them into cuttings, and inserted them thickly in 5-inch pots, in a gritty compost, placing them in a warm greenhouse. Almost every piece rooted. The cuttings were then potted off singly into small pots, returning them to the same temperature till they had become established, when they were gradually hardened off and placed in the open. During July they were again potted. This time 6-inch pots were used. Some of the plants have reached the height of 3 feet. It remains to be seen whether they will make such long growths as those that are grafted. If they are not so vigorous, they should prove very useful, even if only a few feet of growth is eventually made, either for pots or for planting out generally.—G. ELLWOOD, *Swinmore Gardens*.

A City garden.—One would hardly expect to find much of interest in a garden upon which the sun never shines from November to April, for such is the disheartening situation of St. Andrew's Rectory Garden, near St. Paul's Cathedral. Many plants thrive there nevertheless, and probably the

careful tending they receive compensates, in a large degree, for the absence of light and air. High walls surround this little garden, fog hovers over it more or less from autumn till spring, and even in summer its daily sunshine bath is brief. Some of the plants to be found there are the last one would expect to see, for instance *Manettia bicolor* is quite at home in the greenhouse, and grows and flowers freely. Some flowers have been open throughout the summer, and even now the plants are not quite blossomless. Those whose gardens are similarly situated should not neglect this plant. The Maidenhair Tree (*Ginkgo biloba*) is represented by a flourishing plant some 5 feet high and a good many years old; it behaves so well amid City bricks and mortar that there is a talk of finding it a permanent home out of doors instead of leaving it in its 7-inch pot. A *Heuchera* with inconspicuous flowers has made its home in the rockery, but it is in some danger of being replaced by one more beautiful, as, for instance, *H. sanguinea*, which probably would grow just as well. *Fuchsias*, *Azaleas*, *Ferns* in variety, *Begonias*, and other plants have kept the outdoor garden bright during summer, and there are bulbs asleep among the *Ferns* that will ensure its attractiveness in spring. Some *Crocuses*, *Narcissi*, and Spanish *Irises* in pots in a cold frame are peeping through the soil, giving promise of dainty flowers to come. In the greenhouse *Clivias*, *Coleus*, *Plumbago capensis*, *Palms*, *Ferns*, and other plants are grown, and so satisfactorily as quite to repay the rector and Mrs. Clementi Smith for their gardening labours.—T.

Amalgamation of Dunfermline Horticultural Societies.—In order to provide for the easier working of the societies, on account of the subsidies granted from their funds by the Carnegie Dunfermline Trust, the amalgamation of the Dunfermline Horticultural and Chrysanthemum Societies has for some time been suggested. Meetings were held on October 29 of both societies, and it was ultimately agreed to amalgamate the two. A committee was also appointed to draw up rules and to make other necessary arrangements for the formation of the new society. The following committee was appointed: Mr. S. Bigham, Mr. Andrew Brown, Mr. James Dunagen, Mr. P. Marshall, Mr. James Proctor, and Mr. D. Robertson, with Mr. John Hynd as interim secretary. The amalgamation is likely to further considerably the cause of horticulture in Dunfermline. The generous grants of the Carnegie Trust give the committee every opportunity of making their shows among the best of their kind in Scotland.

CACTUS DAHLIAS

IN THE GARDEN AND IN THE FLOWER VASE.

FEW modern garden flowers are more beautiful, more disappointing, and more utterly bewildering in their behaviour than the Cactus Dahlia. One is positively astounded at the beauty and brilliance of the flowers shown at an autumn exhibition. All are so beautiful one hardly knows which to prefer, and then one remembers with wonder how rarely one sees a group of Cactus Dahlias that is really satisfactory in itself and an ornament to the flower garden.

Determined this time that there shall be no mistake, a dozen or more of these very taking flowers are ordered, and next spring the gardener presents you with some newly-struck plantlets that have just arrived. They are potted, petted, and grown on till they are fit for planting out in that choice, sunny, yet open quarter of the garden set apart for the trial of novelties. By the next autumn it is not unlikely that not more than three out of the eighteen or more you may have ordered have proved of value, either as a decorative plant or as a flower that will stand when cut and in water, and once more you repeat what you have often heard, "Cactus Dahlias are so very

disappointing I really don't care to grow them." It is decidedly annoying, I must say, to find that the loveliest flowers seen at a show, and grown specially for that purpose, are positively of no value in a garden for decorative purposes. But so it is, and therefore one must try to correct this state of things, which with some care and knowledge can be rectified.

One of the most common defects of the Cactus Dahlia is to bury its flowers in the leaves; another will produce its flowers on long stalks, but so pendent that you cannot find them unless you hunt for them. One variety will grow too tall, another so thick and bunched that its flowers are lost in the growth. In fact, the disappointed amateur will tell you the defects are endless, and will add, as a last crushing remark, how utterly useless they are for cutting—that final reprobation of modern gardening that measures everything by the rule of thumb and scissors.

And yet the Cactus Dahlia is a lovely plant, and at its best is quite indispensable to any good garden. Would growers, I wonder, be persuaded to show their new varieties in pots? We should then have some idea of their true behaviour. Would gardeners, young and old, learn the simple art of "dis-shooting" and thinning the superabundant growths of the flowering Dahlia? To those who have not closely observed the growths a flowering Cactus Dahlia makes, I would say—notice that of the two shoots on either side of a flower one is much stronger than the other, and that the weaker one generally has a flower-bud showing. Well then, pinch out that strong shoot, and leave the weak one with the flower-bud, and you will find that shoot will give a succession of flowers that will show above the leaves, while if that strong shoot were left it would smother the flowering shoot. This principle once understood, and the grosser leafy growths suppressed, you will no longer complain of your Dahlia bushes being flowerless in effect, and, with the knowledge that comes from experience, you will by degrees transform your leaves into glowing heads of flower.

There are already a few Cactus Dahlias of faultless habit, even when grown on strong soils and in cold climates. I will specially mention *Britannia* and *Amos Perry* as examples of what a Cactus Dahlia can be. I dare say great growers can give us the names of many others as good or nearly so, but there are many that, with the precautions I have mentioned, are well worth the trouble incurred; but when it comes to requiring flowers that will live in water for days even when cut with long stalks it is the new narrow-petalled, pointed flowers that stand best. Cut boldly, strip off the leaves, save one or two, and plunge the stems in big vases that hold plenty of water, and you will find the Cactus Dahlia is a lasting decoration in the hall or any fairly cool room, when such varieties as the following are chosen: Of reds and crimsons *Red Rover* and *Amos Perry* are most enduring. *Gabriel*, a lovely flower with white tips to its pointed petals, is the most lasting Dahlia I know as a cut flower, and its habit is excellent. *Mrs. J. J. Crowe* is the most lasting and prettiest of yellows in water, while *Mrs. E. Mawley* is most disappointing, both in the garden and in the vase. Oddly enough, I have not found a good buff for cut flowers with long stalks, but *Khaki*, when cut short and in a low glass, will last three days.

There are many, such as *Britannia*, *Mary Service*, *Laverstock Beauty*, and other more delicately coloured flowers, that live perfectly well, and may be cut with long stalks; but of the very rich-coloured crimsons *Red Rover* is

most lasting, and stiff in petal and stalk, while Winsom is the only white that I know that is effective in the garden and fairly lasting as a cut flower. I do not attempt to grow many varieties myself, so I can only speak positively of those I have watched and tried. Others, I hope, will give their quota of knowledge, and so conduce to the growth of the Cactus Dahlia, which is really one of the most splendid additions to the garden in autumn.

EDWARD H. WOODALL.

CACTUS DAHLIAS FOR THE FLOWER GARDEN.

STATEMENTS are occasionally made in the gardening Press to the effect that the present race of Cactus Dahlias, so much prized for exhibition purposes, are of little, if any, value, through defects in habit, for garden decoration. Several very sweeping statements to this effect have been made recently, it is to be feared, by persons quite inadequately informed as to actual facts. A plantation of Cactus Dahlias grown entirely to supply blooms for exhibition purposes, planted in rich soil, probably thinned and disbudded, heavily mulched and freely watered, cannot be expected to display much decorative value, as the conditions under which the plants are cultivated are hostile to normal development. But when the plants are placed out in ordinary garden soil to produce stock, a practice with many growers for sale, the natural habit of the plant is exhibited, and it is seen what excellent subjects many of the varieties make for garden decoration.

In order to give a practical test as to the fitness of certain varieties for employment in the border, I applied to eight firms who cultivate Cactus Dahlias on a large scale, viz., Messrs. Burrell and Co., Cambridge; J. Cheal and Sons, Crawley; Hobbies (John Green), Dereham; S. Mortimer, Farnham; F. W. Seale, Sevenoaks; J. Stredwick and Son, St. Leonards; C. Turner, Slough; and J. Walker, Thame, to supply the names of the best eighteen varieties of Cactus Dahlias for garden decoration, old and new, and the large number of eighty-two varieties were sent in. Of this number Mrs. H. L. Brousson, pale salmon and yellow, received seven votes; Britannia, salmon-pink, and Mrs. E. Mawley, yellow, five votes; Amos Perry, shaded crimson; Effective, amber and rose; Eva, white; Floradora, deep crimson; H. J. Jones, delicate primrose and pink; and J. H. Jackson, maroon, four votes each; Clara G. Stredwick, bright salmon; Comet, bluish, striped crimson; Coronation, bright fiery scarlet, classed as a Pompon Cactus from being undersized; Dainty, yellow and pink; Mabel Tulloch, clear rosy pink; Mary Service, pink and salmon; Mrs. de Luca, deep yellow; Prince of Yellows, Sirius, bright yellow, striped and speckled with crimson; Uncle Tom, maroon; Violetta, violet-rose; and Winsome, white, each received three votes.

Other varieties receiving a less number of votes were Aunt Chloe, Carmen, Captain Broad, Countess of Lonsdale, Conrad, Cheal's White, Columbia, Dorothy Vernon, D. A. Dunbar, Etna, Florence Tranter, Farnham Favourite, Fred Cobbold, Freedom, General French, George Gordon, Gaillard, H. T. Robinson, Hereward, H. W. Sellean, Iceberg, Isis, Imperator, J. W. Wilkinson, Lyric, Lottie Dean, Mr. Seagrave, Mrs. Spencer Castle, Manxman, Mrs. Jas. Bailey, Mrs. John Barker, Mabel Needs, Mrs. Sanders, Marconi, Miss Grace Cook, Magnificent, Miss F. M. Stredwick, Mrs. J. J. Crowe, Mrs. H. J. Jones, Mrs. J. W. Wilkinson, Miss Winchester, Mrs. D. B. Crane, Mrs. McKergow, Mayor Weston, Owen Murrell, Orion, Osprey, Percy Mortimer, Peace, Phineas, Queen Alexandra, Regulus, Spitfire, and Yellow Gem.

Looking over the foregoing varieties, it would appear that flowers having shades of salmon and related tints are among the best adapted for border purposes. Mrs. H. L. Brousson, which stands at the head of the list, through having obtained the highest number of votes, is pale salmon and yellow; and several more of similar shades of colour are decidedly high up as decorative sorts. The

average height of the varieties named would be from 3 feet to 5 feet, a difference in height which is desirable, as in a border planted with Dahlias it is desirable some should be taller than others in order to form a background, and it is satisfactory to note that many of the newer sorts possess a greater freedom of bloom than the popular varieties of a few years ago.

R. DEAN.

COLOUR IN THE MIXED BORDER.—V.

AFTER the dazzling colour scheme which has occupied our attention in Sections 1, 2, 3, and 4, it is quite refreshing to turn to the mental contemplation of the white flowers that are at our disposal in such profusion. We can even be hypercritical, and choose only the sweetest and fairest for what, I think, will be the prettiest of all the sections.

If it is considered suitable, you might begin with planting at the back of the border a well-grown bush of white Lilac Marie Legrange or alba grandiflora, Weigela Lavalley, and the graceful white Broom. These three shrubs will give white flowers for some weeks of spring and summer. Chrysanthemum maximum will follow, with Foxgloves, Spiræas, and Hollyhocks; and finally, for the autumn, there are the Phloxes and Pyrethrum uliginosum. The latter is much prettier, and flowers twice as well if you cut down its first growth a little. The delicately coloured varieties of the white star Asters, as well as the larger blossomed sorts, are now practically inexhaustible. If you like the idea of clumps of Sweet Peas, these can be repeated, Blanche Burpee and Giant White, being sown for the purpose, in heat, in February. Next in height come the perennial Lupins, charming double white Columbines, Campanula pyramidalis, and C. persicifolia, Rockets, double and single, Malva moschata alba, and Achillea (the Pearl). The Achilleas must be carefully staked and tied up, or they soon become unruly. Now comes the portion of the section for a charming display of Lilium candidum, which will be all the better for having their stems hidden by the surrounding foliage. Lilium longiflorum can be planted a little further forward, and in about the same neighbourhood Lilium speciosum album will be very effective for autumn flowering. For the autumn, too, Hyacinthus candicans is charming, and no trouble to grow; it is contented anywhere, and increases rapidly. The Bride Gladiolus is not so accommodating, but it will flower, if it chooses, in early summer, with the Spanish Iris Blanche Superbe. Canterbury Bells, double and single, and white Sweet Williams, giant and double; Antirrhinums and Pyrethrum Boule de Neige. Anemone japonica must be planted here, and white Carnations, of which there are so many good sorts. For spring, plant The Bride Anemones, and for the same season the fragrant double Narcissus, which must never be lifted, or it will produce blind buds. More towards the front you can put tall Tulips for grace and Hyacinths for sweetness, and white Pinks for May and June. I believe the valuable Mrs. Sinkins has at last been superseded by Her Majesty, and I hear of another white one, Florence, grown by Ladham. But in spite of the superior flowering qualities of these novelties, nothing will persuade me to give up the dear old-fashioned small kind, which flowers so early, and fills the summer air with the spices of Araby. Iceland Poppies must not be forgotten, for they are the most faithful of all our

biennials. Then come the Primrose tribe (but the white varieties are few), Pansies and Violas, the modest Hepatica (which once planted must never be disturbed), and the white Bluebells, or more properly Squills, which are so pretty in spring. With the Arabis, or Rock Cress, and Woodruff (Asperula odorata), for filling in, we may complete our list of herbaceous plants.

The list of white annuals is so long that I cannot attempt to record them all. Those I should recommend are: Godetia Duchess of Albany, double Jacobæa, Schizopetalon Walkeri, Sweet Sultans, Candytuft, Clarkia alba, Scabious, China Asters, Ten-week Stocks, Malope (a good late flowerer and not afraid of frost), Stock-flowered Larkspurs, and Lavatera alba. Phlox Drummondii is particularly charming in its white form, but it must be well pegged down. Again, I should recommend the free use of foliage plants to intermingle with the white flowers, and no bare spaces should be allowed if it is possible to avoid them.

Now we come to pink—for Section No. 6—and I think this will be the most difficult one to deal with. It is not that there is such a scarcity of pink flowers, but it is that the tone of many is so unsatisfactory, for a disagreeable mauve tint seems to pervade most pink flowers. There are also very few tall plants for the background, so I think we must have recourse to some of the charming shrubs for our spring blossoming. Weigela rosea, Azaleas (the latter, if they have a little peat bestowed on them, will thrive perfectly), double Peach, and Thorns—all delightful colours. Sweet Peas may be planted. I think Queen of the Pinks would do, though it is a trifle "salmony"; but we must not be too particular about shades. The pink Hollyhocks are the prettiest of all. There is, too, a pink Columbine, Canterbury Bells, double and single; Sweet William Pink Beauty, the true Leander shade; and Antirrhinums, quite a novelty; Peonies, double and single; Pyrethrums, hardy Chrysanthemums, and Gladiolus for autumn flowering, with pink Anemone japonica, Raby Castle Carnations, and Shirley Poppies. Miss Willmott Verbena, the finest ever grown, would be very useful pegged down towards the foreground, where we can have Hyacinths, pink Squills, Tulips, Primroses, Hepaticas, and double Daisies.

For the autumn, alas! we have no tall flowering plants, and the background will be dull and flowerless; but climbing Roses might be trained on poles—Dorothy Perkins, for instance, and others of like value. These would give a second bloom when most wanted. Annuals are by no means scarce; China Asters of different sorts, Nemesis, Ten-week Stocks, Godetia, Eschscholtzia, Saponaria calabrica, Silene pendula, and Scabious, besides many others if they are wanted.

Towards the background of the pink section I should plant a group of Humea elegans. It is a thing that has gone out of favour of late years, owing, I believe, to its having contracted one of those mysterious diseases which seem so often to affect over-cultivated plants. It is a half-hardy biennial, and must be grown from seed sown in heat the previous July, and planted in well-manured soil. It is very graceful with its grass-like foliage and heads of reddish brown feathers, and it is also pleasantly aromatic. It must be well staked, as the feathery heads catch every breath of wind. I should also mix with the flowers in your pink plot, foliage plants of a pink, or brownish tone; you have no idea how well it looks. The pure green is a little crude with pink.

AUGUSTA DE LACY LACY.

TREES AND SHRUBS.

NEW FLOWERING SHRUBS.

OF the numerous additions to our hardy flowering shrubs that we owe to the skill of the hybridist, many have originated at M. Lemoine's nursery at Nancy. An enumeration of them all would be a lengthy matter; but of flowering shrubs alone especial mention may be made of the genera *Deutzia*, *Philadelphus*, *Ceanothus*, *Weigela*, and *Syringa* (the Lilac); of the last he has raised all the numerous double-flowered forms now in cultivation. In the autumn catalogue just issued the following novelties among hardy shrubs are announced:

Deutzia Lemoinei Fleur de Pommier.—The original *D. Lemoinei*, now so popular for forcing, resulted from the intercrossing of *D. gracilis* and *D. parviflora*, whereas the new variety is announced as a seedling from *D. Lemoinei*, whose flowers had been fertilised by the pollen of the Chinese *D. discolor purpurascens*. In the variety *Fleur de Pommier*, the flowers, which are freely borne in clusters of twenty to thirty, are of a soft rose colour fading to white. In habit it is the counterpart of the variety *Boule Rose* (of the same origin), but differs in the form, size, and arrangement of the panicles and flowers.

D. myriantha.—Obtained by crossing *D. corymbiflora* with *D. parviflora*. The flowers disposed in large branching corymbs are borne in great profusion. They are of a snowy whiteness, and as large as those of *D. Lemoinei*, which they resemble in shape, the stamens forming a little yellow cluster in the centre of the flower. Its blossoms usually appear about June 10, at the same time as those of *D. crenata*, and some eight to fifteen days earlier than those of *D. corymbiflora*. The plant is hardy and proof against late spring frosts, which often destroy *D. corymbiflora* to the ground level.

D. Vilmorina.—This new species, named after Mme. Maurice de Vilmorin, was discovered in the mountainous districts of Se-Tchuen (China) by l'Abbé Farges, who sent seeds to M. Vilmorin in 1897. It is a shrub from 3 feet to 4 feet in height, but will probably be grown taller. The flowers are borne twenty to thirty-five together in thyrseoid panicles, which are at first upright, and then spread horizontally; they are snow-white, measuring 2½ centimetres in diameter—that is to say, almost as large as those of *D. discolor grandiflora*. It is quite hardy, and begins to flower about the first week in June.

Philadelphus Lemoinei Rosace.—Another addition to the numerous delightful forms of *Philadelphus Lemoinei* which have become so generally popular in gardens. In this the flowers, borne three or four together in each axil, are as much as 7 centimetres in diameter, with two or three rows of petals, creamy white, changing to pure white, with the agreeable odour of the original *P. Lemoinei*.

Syringa vulgaris Réamur.—A single-flowered Lilac, whose flowers are borne in large thyrses as broad as they are long. The blossoms are of a deep carmine-red and of a satiny texture.

S. v. Deuil d'Emile Gallé.—A double-flowered variety, with very large blossoms of a mauve-carmine colour, with the buds purplish.

S. v. Waldeck-Rousseau.—Flower clusters as much as 30 centimetres in length, but lightly disposed. The blossoms are of a soft lilac-rose, with a white centre, a charming tint.

Weigela (Diervilla) précoce Conquérant.—A few years ago M. Lemoine gave us the first of the early-flowering *Weigelas* in *W. précoce*, reported to be an importation from Japan; since then he has put others into commerce. The variety *Conquérant* is said to bear very large flowers of a deep rose-lake, with the outside carmine.

W. précoce Glorieux.—The blossoms, which open about May 8, are numerous, of good shape, and in colour mauve-lake, with the reverse of a deeper hue.

W. p. Gracieux.—Flowers white, with a sulphur throat, while the outside of the blossoms and the buds are of a salmon tint. Commences to flower by May 10.

THE RED OR RIVER BIRCH.

(BETULA NIGRA.)

THIS Birch is very distinct from our own *Betula alba*, as it lacks the grace and elegance of the common kind; still it is as an ornamental tree certainly entitled to more attention than is usually given it, for the Red Birch is one of the most picturesque trees we possess. It forms a free, bold-growing specimen, often divided into several large branches at but a little height from the ground. The branchlets are not so numerous as in the common Birch, and lacking the elegance of this last, the Red Birch forms a tree of totally different aspect. The bark, however, is pretty in winter, as it partially peels off and remains attached to the stem and principal branches in flakes, which give to a good specimen of it a wild and picturesque appearance. The old bark in this semi-detached state is of a reddish cinnamon colour, while the young which is thus exposed is a kind of brownish buff. At a little distance the trunk and principal branches appear to be much stouter than they really are, by reason of the loose bark. On dry, gravelly soils the Red Birch, though it will there hold its own, is of rather slow growth, while in moister spots it makes much more rapid progress.

burnished silver. Then two varieties of the White Birch are as distinct from each other as it is possible for two members of the same species to be. I allude to the very pendulous form *Youngi*, many of whose branches hang down almost perpendicularly with the main stem, and *fastigiata*, which is nearly as upright as a Lombardy Poplar. The Paper Birch of the United States (*Betula papyracea*), the bark of which is used by the Indians for the construction of their canoes and numerous other purposes, is another of the Silver Birches, but, as a rule, less drooping than the common white Birch.

H. P.

NOTES ON HARDY PLANTS.

HESPEROCHIRON PUMILUM.

WRITING in THE GARDEN of June 18 concerning *Hesperochiron californicum*, "W. I." observes he has not seen the above plant in a living state. What was supposed to be *H. pumilum* flowered on the rockery at Hale Farm Nursery, Tottenham, in June, 1880, I believe, for

PREPARATORY WORK FOR TRANSFORMING A CINDER TENNIS COURT INTO A ROCK AND WATER GARDEN AT PARK HOUSE, READING. (See page 327.)

A group in the park, especially near water, or a single specimen on the lawn, will display the characters of the Red Birch to the best advantage. It is a native of a large district in North America, and is quite hardy in this country. As a timber tree it is in considerable demand in America, as it is said to be a close-grained, handsome wood, which can be easily stained exactly to resemble Walnut. It is just as easy to work, and is suitable for all, or nearly all, the uses to which Walnut is put. There are large forests of this Birch throughout Canada growing in various positions. From a timber point of view, that from the higher and drier districts is superior to that grown in damper spots. A group of the various Birches, now they are devoid of foliage, shows the great variation in habit that is to be found among them, even more conspicuously than can be noticed during the summer months. For instance, a direct contrast to the Red Birch are some forms of the common kind, whose bark is of such dazzling whiteness that their boles glisten in the sun like

I am writing entirely from memory. The plant I refer to Mr. Moon made a drawing of, and an illustration of the plant appeared in THE GARDEN some time later. But the plant I remember, which flowered well and freely, does not agree with the description given of it by "W. I.," who describes the white flowers as "veined with violet and with a yellow base." The plant that flowered at Tottenham had pure white flowers, without any of the colour markings I have mentioned above. As the leaf characters given of *H. californicum* by "W. I." so nearly agree with the Tottenham specimen, it may be the latter was not true to name. The Tottenham plant had decidedly oblong spatulate leaves of the size of those of *Omphalodes Luciliae*, the low, tufted growth slightly spreading, the segments of the pure white blossoms so deeply cut that the tips extended in a flattish direction. I have only seen the plant on this occasion, and have frequently enquired for it, but in vain. Doubtless the back numbers of THE GARDEN will contain a note of the plant, which at the time

interested me greatly, and possibly some other information that I am not now able, with the lapse of nearly a quarter of a century since I saw the plant, to give. If I remember, however, the plant at that time excited interest among botanists generally, as it was an entirely new genus. The plant was certainly a very beautiful subject.

Hampton Hill.

E. H. JENKINS.

SALVIA RUTILANS.

THIS *Salvia* lives out of doors unprotected winter after winter in the south-west, and forms large bushes. In Nicholson's "Dictionary of Gardening" its height is given as from 2 feet to 3 feet, but I have now in my garden a great bush over 6 feet in height and 8 feet through covered with flowers. It cannot compare for effect with *S. splendens grandiflora*, but its cherry-red bloom-spikes are pretty, and the delicious scent of its bruised foliage, which has led to its being termed the Pine-apple *Salvia*, entitles it to rank with *Aloysia citrodora*, the Lemon Verbena, and *Eucalyptus citriodora* as one of the most fragrant-leaved plants. S. W. F.

FRANCOA RAMOSA.

THIS pretty Chilean plant, better known under its English name of Maiden's Wreath, is perfectly hardy in the open in the south-west. A large plant 2 feet to 3 feet across, bearing dozens of tall, branching flower-sprays, set with numberless pure white blossoms, is a beautiful picture in early August. In the Tresco Abbey Gardens, Isles of Scilly, and in the south of Ireland it also flourishes amazingly. Two other species—*F. appendiculata* and *F. sonchifolia*—are also grown, but they lack the beauty of *F. ramosa*. Over the greater part of the country *Francoa ramosa* is grown as a greenhouse plant, and is very valuable for conservatory decoration. They may be wintered in cold frames, and take up but little room at that season of the year. They are easily propagated by division of the roots in the spring just as growth commences, or may be raised from seed, of which a quantity is produced. S. W. F.

A GENERAL CALENDAR.

HERBACEOUS BORDERS.

FROST and the necessity of making a clean sweep of all dead and decaying flowers will give an opportunity of getting to work on herbaceous borders as soon as possible with a view to most of the work being done before severe frost sets in. This will put an end to all operations of this kind. All things that are better for annual lifting and replanting should now receive attention, and unnecessary plants taken away. Borders of this kind should be planted as naturally as possible, care being taken not to have absurd mixtures, and never allow one species to encroach unduly on another. Due regard should also be taken as to the height of the different species, and if any mistake has been previously made it should now be rectified.

Aubrietas.—These beautiful spring-flowering plants are always best when propagated from cuttings if it is desired to increase special varieties. A few, such as *A. violacea*, *Hendersoni*, and *Leichtlini*, seed somewhat freely, and each one fairly reproduces its kind, but it is wisest to depend on cuttings for the perpetuation of character. Cuttings taken in the spring and rooted in nursery beds should now be in good order for planting out; if this is attended to without delay a profusion of bloom may be looked for in the spring. Old clumps may be lifted, and if carefully pulled to pieces and replanted will soon make nice plants; but these seldom do so well as plants from cuttings.

Myosotis dissitiflora.—No spring-blooming plant is more beautiful than this Forget-me-not, and no hardy plant so unsatisfactory when increased by cuttings, yet no plant lends itself to this method more readily. Now that clumps or masses of shoots

are showing incipient stem-roots, it is only needful to pull them off and dibble them in, and they are well rooted in a couple of weeks. But all such plants are very unreliable. Some do well, some do not, even the best, however, never bloom well or consistently, hence they are in the spring disappointing. There is no better way to get this interesting plant in good form than by raising from seed. Seed sown early in August in the open ground always furnishes good plants to put out in November, and if the plants when taken from the beds in May are planted out on a north border they will in all probability furnish enough self-sown plants for all requirements.

Forcing Rhubarb.—Owing to the dry weather experienced of late *Rhubarb* matured early, and should therefore be ready for forcing. If desired earlier than usual, any variety may be forced, but the early red-stalked forms are the quickest to give young stalks, and are to be preferred for early supplies. If the clumps are lifted and placed in a rather strong heat they may fail to start satisfactorily; they would do better if first subjected to a frost or two. The number of clumps likely to be required should be partially cleared of soil and introduced into heat after exposure to frost.

Horse-radish.—If neglected such a hardy subject as *Horse-radish* never pays, the roots become tough and do not swell to a useful size after they become thickly matted together from having occupied the same ground too long. To get good results the ground should be deeply dug, burying a good quantity of manure some 18 inches deep, and then planting with a dibber in holes which nearly reach the manure. By these means shapely roots can be obtained, which may be used with very little waste; advantage should be taken of the present season to do this kind of work. If left till the spring, with a rush of other work, this necessary operation may be neglected.

Tomatoes.—Stores of outdoor *Tomatoes* still being ripened up in warmth must be looked over frequently, and any fruits showing the least signs of decay must be removed, as decay spreads through a box or shelf of fruit very rapidly. For the kitchen these stored fruits are most useful, and they help to eke out the supply without coming too hard on the winter-fruited plants.

Lilium Harrisii.—Where a stock of this *Lily* is required for flowering in pots no time should be lost in obtaining the bulbs if this has not already been done. If the bulbs are potted and placed in a cold frame, the lights of which are only used to ward off the heavy rains, they will root slowly and surely, and may be had in flower nearly, if not quite, as late as those kept out of the ground so much longer. Where required for early blooming, the bulbs should of course be potted as soon as possible, so that they will at once commence to root, for it is useless to attempt to force them till the pots are well filled with roots.

Norwich.

T. B. FIELD.

THE FLOWER GARDEN.

PLANTING BULBS IN GRASSLAND.

IN this class of gardening failure is more evident than success. There is more than one reason for this. A by no means unusual source of failure closely follows on the heels of those who plant bulbs in grass lawns, in all probability the worst place in creation. Any good lawn, to keep it good, is subjected to a very heavy rolling many months in the year. In this way the under-sod becomes so consolidated that the bulbs literally have no chance whatever. This is especially true when the turf is raised, the bulb dropped in, and the turf firmly trodden down again. In the first place, the lawn is not usually a good place, and the mode of procedure is wrong. Even in woodland grass there are too many failures, and usually there is a due want of preparation. The round cheese-taster-like knife is not, as a rule, suitable for the work, and the dibber, where it can be used, is even worse. Where a real success is desired a slope, and better if rarely rolled, is one of the best

positions to deal with. In such a place the under-soil is of a "maiden" character generally well suited to the work. Much trodden woodland walks, when of grass, as they should be, are not the best, but the sides of these are invariably excellent, because less firm. In the case of the latter bulbs may be freely planted with good hope for success. Twenty-five years ago in woodland side walks and adjacent grass land I planted large numbers of spare bulbs, and to see them in flower nestling in pretty colonies or tufts was a pleasing sight. But our favourite planting tool was the grubbing axe, so-called, or mattock. With this an irregular piece of turf several feet long and 1½ feet wide was torn up, the lower soil was next picked up with the same tool, and about half removed when the bulbs were thinly placed in and covered with soil. As to the turf, we rarely replaced the one-half of it, and the little that was relaid was broken up by the hand in pieces not larger than a man's palm, and placed thinly over the spot. In this way there was a minimum of resistance to the bulb growth in spring, and with a thin carpet of grass in the first year or two we had little difficulty in establishing anything in the way of bulbs. The method is simple and easily adopted. Where larger areas have to be planted it is quite simple to repeat the above as many times as desired. Much depends on the soil below as to the amount of success. In some woodland grass, for instance, the more delicate varieties are quite happy. The white *Ajax* *Narcissus* and *Queen of Spain* are notable examples of this success. Were I using the rounded bulb planter introduced by Messrs. Barr, it would be rather for the making of the holes only. The piece of turf cut out I would discard, and instead of it, when all the bulbs were in position, some good soil would be sown broadcast and swept into the holes with a hard broom. Far too much has been made of stoppering up these nicely cut holes, and those who prefer to achieve success in grass gardening will do well to take less note of it. A bulb of *Narcissus*, if thrown down on rough grass, will not only root into the sod, but even in the first season half bury itself from view, and presently the bulbs will be quite covered up, not with decayed vegetable matter as one would suppose, but with fibre and turf. I have instances of this myself. To a considerable extent the bulb will look after itself. The ordinary pickaxe is also a good tool for bulb planting. Lay down a rope in a zigzag outline, and with the point of the pick make the most informal of groups. The same tool will speedily form channels or holes as you will. In large groups, however, it is best to take up the turf, pick up the soil thinly, and irregularly plant the bulbs. Replace the soil only moderately firmly, and break up and relay about one-half of the turf. There may be positions to be planted where this last would require modification. In woodland or pasture a good lesson may be secured from the way the fallen leaves are drifted by the wind, and the long drift is especially good for copying. I have done this very often.

E. H. JENKINS.

DAY LILIES.

No amateur should be without some species at least of these hardy and easily-grown plants, which, with their flowers of varying shades of yellow and orange, are very decorative subjects for the border, and although the individual blossoms are unfortunately fleeting, they are produced in such quick succession that the scapes, through the flowering season, are never without expanded blooms. Day Lilies revel in a moist soil, and never exhibit such vigorous growth as when planted by the waterside, where their roots are always moist. The stronger kinds are well adapted to planting in open spaces in the wild garden, but the soil should be well enriched before they are put out, and rampant-growing herbage rooted out around the space they are to occupy. They must be planted in the full sunlight, for under trees they will not flower satisfactorily, a large colony of *Hemerocallis fulva*, many yards in circumference, that I know of, which is rather shaded by trees, not having borne a single flower for ten years. Those who have no waterside

site available need not be deterred on this account from embarking on the culture of Day Lilies, for although the proximity of water induces exceptionally strong growth, they will succeed and flower well in the driest garden. My garden slopes steeply to the south and is very dry, the soil being light and stony, though fairly deep and the sorts of *Hemerocallis* mentioned all do well with me.

H. aurantiaca major.—This is undoubtedly the finest of the whole race, bearing large orange-yellow flowers over 6 inches across, the petals of which are of great consistence on stems from 2 feet to 3 feet in height. It has a lengthened blooming period, my clump perfecting its first flowers in June, and continuing to blossom until September. Complaints have now and again been made that this species is very shy in blooming, and last year a correspondent wrote: "The one reason why *H. aurantiaca major* fails in so many gardens is just lack of moisture." As in my dry garden it flowers profusely this statement is fallacious. It was introduced from Japan in 1895, so is still a comparatively new plant.

H. Dumortieri is a rather dwarf-growing species, about 2 feet or rather less in height, bearing soft yellow flowers tinged with orange 3 inches across; these are flushed with red on the outside of the petals, and are borne four or five on a scape. It is a June flowerer and its bloom-spikes lean outwards. It was introduced from Japan in 1833.

H. flava.—One of the commonest species as well as one of the best. It flowers in early June, throwing up numbers of bloom-scapes about 2 feet in height bearing clear yellow, deliciously fragrant flowers some 3 inches across. It is a native of Siberia and Japan, and has been known in this country over 300 years.

H. fulva.—A vigorous species, bearing orange-brown flowers 4 inches across on scapes about 4 feet in height in July. It is the least ornamental of the species named, but associates well with the Madonna Lily, its tawny brown forming a good contrast to the satiny-white spires of the Lily. It was introduced from Japan about the same time as *H. flava*.

H. Kwanso flore-pleno fol. var..—This is always handsome as a foliage plant, its variegated leaves being very ornamental. There is considerable diversity in the variegation, some plants having white leaves with narrow stripes of green, some green leaves with thin white lines, while in others the green and white alternate in equal proportions; of these the first is the most decorative. The flowers are semi-double, reddish buff in colour, 4 inches across, and carried on scapes 3 feet to 4 feet in height.

H. Middendorffii.—A dwarf species 18 inches in height bearing rich orange flowers, five on a scape, 3½ inches across, in June and July. It is a native of North-Eastern Asia.

H. Thunbergii.—A most attractive species, bearing pale sulphur-yellow scented flowers about 3½ inches across, on scapes branching tier above tier, in July and August, thus forming an excellent follower of *H. flava*. The scapes attain a height of about 2½ feet to 3 feet. The plant is a native of Japan.

The newly-introduced *H. citrina* I have not got. Besides the species named there are many hybrids, some of these being attractive flowers. The species *H. graminea* or minor is a dwarf plant suited for the rock garden.

In planting Day Lilies I have always enriched the soil to a depth of 2 feet 6 inches with rotten manure

and leaf-mould, so that, although their situation is a dry one, they are well provided with rich food. Doubtless the heights given would be greatly increased if the plants enjoyed abundant moisture. S. W. F.

VERBENA VENOSA.

This old-time favourite is now rarely met with. It is a pity, for the purple *Verbena* is much too good to be altogether neglected. In many places it is hardy enough to winter in the herbaceous borders, with some slight covering as a protection from severe frosts. In colder gardens the plants should be lifted at this time of the year and have the fleshy roots planted thickly in boxes and wintered in cold frames. In the spring the plants are easily propagated by division. *Verbena venosa* thrives in any well-worked garden soil, and

CAVE AND WATERFALL IN THE ROCK AND WATER GARDEN AT PARK HOUSE, READING (FORMERLY A CINDER TENNIS COURT).

does not object to a little shade; but it is seen at its best when growing in the full sunshine. On bright days it is interesting to watch the shy humming-bird hawk noth daintily fitting over its flowers, for which it evinces a decided preference. *Verbena venosa* is not liable to attacks of mildew, nor does it fall a victim to the disease which spoils the florists' varieties, and, like the *Begonias*, a heavy shower only serves to make the flowers appear the brighter. It should be planted rather thickly, and is very effective when massed. Its peculiar shade of purple contrasts well with most yellows and bronzes. A very pretty and uncommon bed may be made by mixing it with *Calceolaria amplexicaulis*, and edging the whole with *Pelargonium Manglesi variegatum*.

A. C. BARTLETT.

THE ROCK GARDEN.

ROCK GARDEN-MAKING. — XIX.

WATER IN THE ROCK GARDEN.

HAVING already pointed out the advantages of water in the rock garden, I will now deal with the various forms in which this might be most suitably introduced, such as ponds, Lily pools, waterfalls, bog gardens, streamlets, &c., and I will give practical hints and illustrations.

PONDS AND LILY POOLS.

The most favoured form of water in connexion with a rock garden is probably a Lily pool or pond, and—provided a sufficient supply of water is available to prevent its becoming stagnant—a pond is an excellent means not only of making the rock garden more picturesque, but also of providing it with a most useful element, for a pond among the rocks enables us to grow choice Water Lilies and other aquatics or semi-aquatics; it also enables us to sprinkle the rock plants with water of the same temperature as the air, and, finally, it produces, through constant evaporation, a moist atmosphere, which is most beneficial to alpine plants from high mountain ranges.

THE SIZE AND SHAPE OF A POND

must naturally depend a great deal on circumstances. The size, of course, will have to depend on the ground, the facilities for excavation, &c., and, above all, the size of the rock garden itself. It is well to bear in mind that it is always advisable to avoid a crowded appearance, and that it is most desirable to be able to walk around the greater portion of the pond and to have access to the various plants used. Rather than bringing the pond close up to, say, a high and abrupt bank of rocks, it would be a better plan to make it a little smaller and allow for a space, wide enough for walking upon, between the pond and any high rocks adjoining it.

As to the shape, we must look to Nature as our guide, and observe her ways of forming ponds and streams. I mention streams because a natural pond, after all, is in most cases only a naturally widened stream, and subject to the same natural laws

in its formation. Let us for a moment follow in imagination the course of a natural streamlet in its meandering through a rocky district. The natural consequence of flowing water coming into contact with a projecting piece of rock will be to divert the course of the stream to the opposite bank, and if that bank consists of material softer than the rock, the washing out of soil and the production of a hollow place will be the inevitable result. If, then, in the construction of the rock garden pond we wish to give that pond or pool a natural appearance we must bear this in mind. In other words, roughly speaking, in Nature's streams and ponds a convex outline of one shore-line would have a

THE ROCK AND WATER GARDEN AT PARK HOUSE, READING, NEARING COMPLETION. FROM A PHOTOGRAPH TAKEN FIVE DAYS AFTER THAT OF THE FIRST ILLUSTRATION.

more or less concave outline on the opposite bank, and *vice versa*. If, therefore, we give to ponds connected with rock gardens an outline of circular, oval, square, or any other regular shape, we blunder. It also follows that when we make a pond in the rock garden the convex portions of the shore-line which project more or less into the water should consist of more massive rocks than the concave recesses, which might well consist of green sward only and suitable plants protruding from it.

WHAT TO AVOID.

An absurdity which cannot be condemned too strongly is the making of ponds in such a way as to have ground much lower than the water-level close to the pond, or, worse still, to have them perched on a hill, or in a high part of the grounds, and to have steep banks supporting the artificially-raised surface of the water. In Nature ponds are formed by water accumulating naturally by gravitation into depressions in the lowest and not in the high parts of the ground. To have a pond on a high level, say on a rocky plateau some distance away from the low ground, may seem right enough, but a depression close to a pond would look ridiculous, as a natural accumulation of water would have filled the low place first.

Another mistake frequently made when making artificial ponds is to allow the walling or cementing of the sides of the pond to be visible above the water-line, showing a distinct line so stiff and hard that no one would ever dream of supposing the pond to be a natural one. To avoid this I construct and arrange all ponds in such a way that a shelf or shoulder runs all around the pond and not less than 6 inches below the water-level. On this shoulder turf or stones can rest, and thus appear continued below the water-line. But of this more anon.

PONDS MADE WITHOUT MASONRY.

Sometimes it happens that the ground on which it is desirable to have the pond has a

subsoil of hard, impervious clay, or that the water supply is so abundant that the soaking away of some of the water into the soil would be of little or no consequence. In either of these cases a very picturesque pond of quite natural appearance might be constructed most easily and without any masonry. If the ground is such that the pond when excavated to the

right depth holds water at the bottom but not at the sides, which consist of more porous soil, an easy method of rectifying this might be adopted. This consists in taking out a vertical trench, say 1 foot to 2 feet wide, all around the pond and at some little distance away from the actual shore-line. This trench is excavated to such a depth that it reaches well into the impervious clay subsoil; it is then filled up with clay, well worked and kneaded to the consistency of "puddle."

When neither sides nor bottom are watertight, puddling with well-worked clay is often resorted to, but as a rule this is unsatisfactory, especially if moles and water-rats abound; these sometimes play sad havoc with ponds, and leaks once made are difficult to locate and expensive to repair. In such a case cemented ponds are best and most satisfactory.

CEMENTED PONDS.

Unless the cementing of a pond is done in such a way that every trace of the masonry can be hidden from view it must be an eyesore. In THE GARDEN of May 14 I gave illustrations of a cemented pond, so masked that the presence of the cement would not be suspected. I will now describe my method of obtaining that result. It consists mainly of a firm shelf 8 inches or so wide and 6 inches below the water level. It matters not whether the bottom and sides of the pond are secured by concrete or by walling with stones or bricks as long as it is made watertight, but the shelf or shoulder is the most important part. As a case in point I give here a further illustration showing the making of a pond at various stages. This I constructed last year for Mr. A. Bartholemew at Park House, Reading when

CINDER TENNIS COURT AT PARK HOUSE, READING, TRANSFORMED INTO A ROCK AND WATER GARDEN.

during the progress of the work I took the photographs from which the accompanying illustrations were prepared. The site was most unfavourable, being, in fact, an ordinary cinder tennis court. Illustration No. 1 shows the preparatory work and the ugly cement work, with the shelf referred to running all around the pond. No. 2 shows the completed work photographed from the same spot. Since then, of course, the plants have grown and developed, and made the difference still more striking.

The third illustration is from a photograph taken only five days later than No. 1; it shows better than words the use of the shelf or shoulder referred to, which forms a firm resting place for stones or turf below the water-line. The fourth picture was also taken only five days later than No. 1, and shows how the ugly box-like structure in the background of the first illustration was transformed into a cave and waterfall. The pond is about 2½ feet deep, and the Water Lilies and other plants with which it is embellished have flourished exceedingly well. The same might be said of the Iris Kämpferi in the margin, and the hundreds of varieties of choice rock plants in other parts of this rock garden not visible in the illustration. Mr. Bartholemew, being a keen enthusiast and a most successful cultivator of those alpine plants which are considered difficult to manage, has succeeded admirably in making his favourites feel thoroughly at home. F. W. MEYER.

(To be continued.)

NEW AND RARE PLANTS.

A NEW HYBRID TEA ROSE.

MESSRS. PAUL AND SON of Cheshunt showed at a recent Royal Horticultural Society's meeting flowers of a new Rose, appropriately named Cherry Ripe. It is a seedling from Mrs. W. J. Grant, and the flowers of quite a distinct red shade, very fragrant, and most welcome in

winter, when this colour is much desired. It is very free, and a hybrid we shall hear much of.

CHRYSANTHEMUM KATHLEEN THOMSON.

AN award of merit was given on the 1st inst. by the floral committee of the Royal

give space to Chrysanthemums that do not produce an abundance of flowers of good colour and useful size and form. It was shown by Mr. Frank Lilley, St. Peter's, Guernsey.

KNIPHOFIA MULTIFLORA.

MR. W. E. GUMBLETON sends from Belgrove, Queenstown, Ireland, a spike of Kniphofia multiflora. The spike measured 19 inches in length, and is closely packed with flowers of a very soft creamy shade, the anthers a clear maize colour; the whole colouring is peculiarly beautiful. It is slender, tapering, and with certain colour associations would make an interesting garden plant. We treasure it for its colour alone. Mr. Gumbleton writes: "It is quite deciduous, and absolutely disappears underground during the winter. It seems quite hardy, as I have never given it any kind of protection. It comes into flower with K. serotina and K. grandis during the latter half of October and the first week in November, and, with the sole exception of the Christmas-blooming species K. foliosa or Quartiniana and K. longicollis or primulifolia (which are practically greenhouse plants, as they cannot perfect their blooms at that late season of the year except under glass), may be considered the last of the outdoor blooming Kniphofias."

ORCHIDS.

CALANTHES.

DURING the winter months few flowers

are more attractive than these, and when well grown none are more useful for decorative purposes. The long, graceful sprays, associated with those of Asparagus Sprengeri, are very handsome in tall vases. But how seldom do we see them in good condition. Some advocate potting the bulbs in leaf-soil, sphagnum, peat, and other mixtures too numerous to mention. Others recommend cow manure, loam, charcoal, and many other things. Few, however, would advocate a strong loam without additions of some kind. Some advocate liberal treatment, while others prefer a sort of starvation culture. Calanthes will put up with almost anything and still keep alive, but this is not growing them. To have them in that state of perfection one sometimes sees they must certainly receive something more than ordinary cultivation. A large batch I have growing in a Melon house would certainly astonish most Orchid growers. They had been under the shade of Melons the whole summer, so had to shift for themselves.

CHRYSANTHEMUM

KATHLEEN THOMSON.

(Given an award of merit in recognition of its value as a market variety.)

Horticultural Society to this Chrysanthemum in recognition of its value as a market variety. Its chief claims to distinction are its profuse flowering habit and the moderate useful size of the flowers. It is of bronze-gold colouring, and originated as a sport from Caprice de Printemps. It will doubtless prove a valuable variety. Growers for market rarely

One would think, with such treatment as this, the foliage would be flabby, and the bulbs and flower-spikes of little worth. Such, however, is not the case, for many of the bulbs are 1 foot or more in length, from 6 inches to 8 inches in circumference at the base, and carrying from three to four spikes each, which, when developed, will be from 3 feet to 5 feet long. In one pot I counted eighteen flower-spikes, and several more from a dozen to fifteen. There was one small pot in particular that attracted my attention. A bulb had been put in the centre of this, and through some cause the old bulb was broken off. Two growths started, both forming fine bulbs. One was carrying four spikes and the other three, making seven to the pot. The plants must have been liberally treated during the growing season, for though the flower-spikes were upwards of 3 feet in length the foliage was quite fresh. It would be interesting to know what some of our great Orchid growers have to say to this, and how they reconcile the no syringing and light shading with the dense shade afforded by the Melons.

Buried Park.

H. C. PRINSEP.

WORK FOR THE WEEK.

DENDROBIUM PHALENOPSIS SCHRÖDERIANUM.

THESE have for some time made a good show in the stove Orchid house, but now are ready for their well-earned rest. Until early March they will only need sufficient water to prevent their shrivelling; if they are well matured very little will be necessary to maintain the pseudo-bulbs plump. It is very desirable that the dormant eyes should not be started till spring. Good growths are only made when the weather is bright. There is nothing to gain and much to lose if they are not kept dormant till spring. This depends entirely upon the watering, for the plants are best in the stove during the winter. They should be well exposed to the light.

DENDROBIUM SPECTABILE AND D. ATROVIOLEACEUM.

Like the foregoing, these two beautiful Orchids are natives of New Guinea, but so far have proved much more difficult to manage under artificial conditions. The new pseudo-bulbs are now finishing, and it is just when the collar roots at the base of the new bulb are being emitted that potting or resurfacing should be carried out. Do not disturb them more than is absolutely necessary. If the soil is fairly good I would advise the removal of the surface material, adding fresh for the new roots to enter. It becomes necessary from time to time to repot them; when that is done remove some of the back bulbs, retaining not more than three behind the new one. Probably retaining too many old bulbs has had a good deal to do with the many failures experienced with these Dendrobiums. A compost of equal parts of fibrous peat and chopped sphagnum is the best, using ordinary pots half filled with rhizomes. Pot rather firmly, keeping the base of the plant and the surface of the compost on a level with the rim of the pot. The plants should be placed in the very lightest position in the stove Orchid house. Winter time is very detrimental to these, for, unlike *D. Phalenopsis Schröderianum*, the growths cannot be matured before the short dull days. The flower-spikes should now be in evidence, but unless the plants are making satisfactory growth they must be removed. Water should be given in limited quantities during the winter season; in fact, after the growths are finished they are best treated in the same way as advised for *D. Phalenopsis Schröderianum*.

DENDROBIUM FORMOSUM GIGANTEUM AND OTHERS.

The flowering season being now over, this useful species, if well matured, will require practically no water during the winter months. A position in the driest part of the intermediate house should be given where much light can reach them. This treatment is also beneficial to *D. Parishii* and *D. primulinum*, and they should remain there till the flower-buds are visible. The growths of *D. Farmeri*, *D. densiflorum*, and *D. chrysotoxum* are matured enough to allow of water being almost withheld, and *D. fimbriatum*, *D. moschatum*, and

the like still require a fair amount of water; but when the terminal leaf is visible allow the plants to become dry before more water is given. They can remain in the house in which they have been grown; reducing the water supply will afford enough rest.

W. P. BOUND.

Clifton Park Gardens, Reigate.

THE KITCHEN GARDEN.

VEGETABLES AT ALDENHAM.

(Continued from page 295.)

CAULIFLOWERS.—The varieties to depend upon are Walcheren and Magnum Bonum, sown early in September, wintered in cold frames, and put out in spring. For a later supply Mammoth, Early Giant, and Autumn Giant are sown in frames and outside in succession. All are given plenty of space. The last-named variety is planted among the early Potatoes, thus utilising the land to the fullest extent. To obtain the necessary succulent growth abundant supplies of sewage are given.

BRUSSELS SPROUTS are largely and well grown. Dwarf Gem, Exhibition, and Northaw Prize are the varieties. About the middle of March the seed is sown in frames, transplanting as required. One of the chief points in obtaining the finest Sprouts or buttons—I do not mean the largest, but the most shapely, firm, and deep green in colour—is the provision of plenty of space. The rows are 3 feet apart and the plants 2 feet 6 inches.

TURNS are largely dependent upon the season, but much may be done to ensure a crop of desirable roots by quick growth and a selection of the right kinds, Snowball, Red Globe, with Milan, Early Forcing, and Jersey Lily for early use.

TOMATOES are grown abundantly and in much variety. Perfection, Ryecroft Glory, Duke of York, and the best of yellow-fruited sorts are prominent. In pots on single stems the plants are grown and in all available sites. It cannot be said that an ideal spot exists at Aldenham for Tomatoes, but the most is made of existing conditions. I noted remarkably heavy crops on plants 4 feet high in 8-inch pots. These were grown sturdily inside until 1 foot high, then placed out of doors to make growth and set a full crop of fruit. In September they were removed to the vinery, where they will give abundant supplies throughout the winter months.

VEGETABLE MARROWS are grown in quantity. White Trailing, Moore's Cream, and Pen-y-byd are the best white-skinned sorts; Perfection and Prince Albert the best green.

LEeks are now highly prized in a collection in September, and onwards especially. They require much skill to bring them to that perfection seen nowadays. Prizetaker, The Lion, and International are the varieties grown. The seed is sown in January in a gentle heat, pricked off into boxes of rich soil directly the plants are large enough to handle, and are finally planted out in trenches as prepared for Celery, with plenty of manure at their base. Rich food is given to induce them to grow quickly. Blanching is carried out by means of wood boxes filled up gradually with suitable soil.

CELERY is largely grown for all purposes; quite 1,000 roots are required. Aldenham Pink, quite a high-class variety raised here, seems to be all that can be desired in an exhibition Celery, being large, solid, yet crisp and with quite a nutty flavour. Giant White, Standard Bearer, and Major Clark's are also grown. Sowings are made in February and March, the plants treated liberally, yet induced to grow sturdily. It is in this way that large, tender heads are obtained which are not pithy. The rows are not less than 6 feet apart, and the plants 18 inches in the rows. The ordinary soil-blanching is dispensed with in favour of encircling the sticks with coils of stiff brown paper, with the exception of those required for winter and spring use. Blanching with paper enables the plants to be continually fed while this process of six weeks' duration is going on.

BEETROOT is often too large at shows, and in that way loses points in competition. The best varieties only are grown at Aldenham, and rich soil is not employed. This crop usually follows the ordinary Celery crop, where the deeply-trenched soil is well suited for the growth of tapering, thongless roots. Perfection and Blood Red are the best long roots; The Globe is the most favoured round variety. The middle of April to the middle of May is chosen for sowing the seed, as too early sowing renders the roots coarse and colourless.

PARSNIPS grow here to an enormous size, yet are quite straight, free from blemish, and of good skin colour. Tender and True, Student, and Hollow Crown are the varieties chosen. The time of sowing is the first week in March on land that has previously been moved deeply. Plenty of space is given for free development of the leaves.

CABBAGES.—The Aldenham Cabbage has always taken a high position in consequence of suitable sorts being chosen and not growing them too strong. Ellam's Dwarf, Flower of Spring, and Winningstadt are the succession varieties grown. The two former are sown the last week in July, and the latter in the month of March. They are sown in boxes in a cold frame. Savoy's A1, Earliest of All, and Drumhead are favoured; the seed is sown in the ordinary way at the end of March or early in April. Broccoli receives much attention. Michaelmas White is equal to Autumn Giant Cauliflower, and is superior to Snow's Broccoli. For later supplies The Queen, Leamington, and Model are encouraged. Of Kales there are plenty to choose from. Those that find favour here are Exhibition, Moss Curled, Emerald Isle, and the Welsh.

LETTUCE in abundance is produced. Of Cos forms Paris Green and Hick's Mammoth are favourites. All the Year Round, Little Gem, and Favourite are good forms of Cabbage varieties.

The manner in which the Aldenham vegetables are arranged at shows is universally admired. Those who consider this phase of exhibiting know what an unusual quantity of Parsley is required to obtain such results. Mr. Beckett grows an exceedingly good variety for this purpose—Dobbie's Selected. It is dwarf, finely curled, and of good colour. The seed is sown in boxes in spring, and planted out in rows on a west border when large enough.

E. MOLYNEUX.

BOOKS.

Bulb Culture.—Messrs. Laird and Sinclair, Dundee, have published a booklet called "Bulb Culture: Which to Grow and How to Grow Them." There are some interesting notes about Hyacinths, Daffodils, and Crocuses in bowls, as well as full details about bulb culture out of doors.

Clibran's Foresters' and Planters' Guide contains much information that cannot fail to be of use to those interested in trees and shrubs. It contains a specially written article on "Planting for Profit," by Mr. J. P. Robertson, head forester to the Duke of Devonshire at Chatsworth. This booklet may be obtained free from Clibran's, Altrincham.

Cucumber Growing Under Glass. This is the title of a useful little book on Cucumber culture. The author, Mr. A. A. Fabius, Redlands Nursery, Emsworth, Hants, deals with the subject thoroughly. Sowing the seed, the best soil, making beds, planting, stopping, tying and training, ventilation, watering, top-dressing, &c., are carefully dealt with. In addition to these cultural details there are chapters upon insect pests, the express system of culture, seed Cucumbers, age and vitality of Cucumber seed, &c. A lecture given by Mr. Massee before the Royal Horticultural Society upon "How to Render Cucumbers and Tomatoes Immune Against Fungus Parasites," is reprinted from the Royal Horticultural Society's Journal. As the notes by Mr. Fabius deal chiefly with Cucumber culture for market, Mr. J. Chidlow has written a chapter upon Cucumbers for a private garden. This book may be had from the author post free for thirteen pence.

Calendar of Garden Operations.—An enlarged edition of this useful little book, based

on the original work compiled by the late Sir Joseph Paxton, has been issued from the *Gardeners' Chronicle* office, 41, Wellington Street, Covent Garden. In his preface the editor says: "The scope of this book has been extended so as to serve the requirements, not of the cottager and allotment holder only, but of the amateur generally." A great variety of subjects are dealt with in the 150 pages, the reader is told how to grow everything required for the kitchen garden, fruit garden, flower garden, indoor garden, and what to do in each month of the year. There are many illustrations that will be found a useful addition to the text.

RHODODENDRON AZALEOIDES.

THERE is a distinct set of *Rhododendrons* characterised by comparatively low stature, bushy habit, and freedom of flowering which are well adapted for massing in the front of shrubberies or for beds on lawns. This set is made up of species, varieties, and hybrids, and the above-named hybrid is one of the number. Apart from being a good garden plant it is interesting from a botanical point of view, as it is one of the few really good hybrids, and probably the first, raised by crossing the deciduous with the evergreen species. It is a very old plant, and has probably been raised in more than one place, as it has been known under a great variety of names, and slight differences occur in both foliage and flowers on different plants. Loudon describes it as having originated about 1820 and being a favourite in collections. Its parents are said to be the North American deciduous species *R. viscosum* and the evergreen *R. maximum* from the same country.

When mature it forms a well-furnished bush 3 feet to 4 feet high and the same through. The leaves are evergreen, and about the size of those of *R. viscosum*. The flowers are borne very freely from the middle of June to the early half of July, and are white, deeply tinged with lilac in colour, and very fragrant.

In some winters it loses a lot of leaves, but is never deciduous. It thrives under the same conditions as other *Rhododendrons*, and always flowers as well as is shown in the illustration. Among its numerous synonyms some of the best known are *odoratum*, *hybridum*, and *fragrans*.

W. DALLIMORE.

GARDENING OF THE WEEK.

FLOWER GARDEN.

CHRISTMAS ROSES.

THE earliest varieties are beginning to show signs of flowering. The surface soil should be pricked over, all weeds, dead leaves, &c., removed. Asprinkling of artificial manure will be helpful, and they should receive a light mulching to prevent the flowers being splashed by heavy rains. A spare frame placed over part of the bed of *Helleborus niger* will serve to keep the flowers clean and of better colour, will also gently force them, and so prolong the season of these useful flowers. It is not wise to close the frame suddenly, and on all fine days air should be freely admitted. It must be borne in mind that the

Hellebores are moisture-loving plants, and that when covered with a frame they will require an occasional watering; for the first few weeks a light damping early on fine afternoons will be beneficial. Failing a spare frame, a few large hand-lights, or even the sides of a fairly large box covered with loose panes of glass may with advantage be used.

VIOLETS.

Continue to remove all runners, weeds, decaying leaves, &c., and when possible hoe between the plants. If a small bed can be covered with a portable frame in the manner advised for Christmas Roses, these will furnish a considerable number of flowers, which will be of value should severe weather set in. The remarks under "Christmas Roses" on watering, ventilating, &c., are also applicable to Violets; but these should be nearer to the glass, so that unless the sides of the frame are unusually shallow it will be necessary to sink them into the ground. When planting the beds in the spring it is a good plan to mark out the size of

but with less robust plants, and those with bulbous or tuberous roots, I prefer to let the foliage remain until all the green, at any rate, has left the leaves.

HELENIUMS.

These most useful perennials have, in common with many allied composites, such as *Rudbeckias*, *Helianthus*, &c., been most showy this autumn. They increase so quickly that it becomes necessary to lift and divide them every second or third year. Where the display is required early in their season, this should be done now; but should it be desired to have the *Heleniums* in flower as late in the year as possible, the work should be deferred until spring. When dividing the exhausted centre of the clump should be discarded, and only the more vigorous growths from the outside be used. *Helenium autumnale* is the kind most frequently seen; its variety *striatum* produces extremely showy flowers. *H. pumilum*, compared with the others, is quite a pigmy; it rarely exceeds 1 foot in height, but its flowers are larger and of a bright yellow. *H. Hoopesii* is rarer than the foregoing;

RHODODENDRON AZALEOIDES AT KEW.

the frame and plant accordingly. By this method the double-flowered Violets may be successfully grown with a minimum of trouble. Of course, during severe weather covering will be necessary.

SPRING BEDDING PLANTS.

Many of the recently planted spring-flowering plants, Wallflowers especially, will require periodical waterings unless heavy rains set in. Transplanted Wallflowers usually flag considerably under sunshine, and on bright days a sprinkling will check evaporation and materially assist the plants. Slugs are unusually numerous, and any infected plants should be lightly dusted with lime or soot.

HERBACEOUS BORDERS.

The borders and beds are unusually bright for the time of year. Except in a few localities there has been no frost, and even the Dahlias are in full bloom. The fullest advantage should be taken of these favourable climatic conditions to ply the hoe freely and frequently in all beds, borders, and the shrubberies, so that the utmost cleanliness may prevail. Many strong herbaceous plants, such as the perennial Sunflowers, Golden Rod, &c., may be cut down and cleared away;

it grows to about 2 feet in height, and its bright yellow flowers are the largest of the genus. All the species and varieties last well in a cut state.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

FRUIT GARDEN.

HARDY FRUIT.

It is very necessary thoroughly to water any large trees before attempting either to root, prune, lift, or replant, owing to the dryness of the soil. Peaches, Nectarines, and Apricots generally receive first attention, and if preparations were made as advised in the calendar of the 1st ult., they will be little the worse for the operation where the work was carried out carefully.

CHERRIES.

Dessert Cherries are also among the first stone fruits to require attention. If growth is too strong the trees should be lifted, or partly so, and replanted, adding a fair quantity of lime rubble and wood ashes, and a well-drained not too rich soil. These Cherries dislike much winter pruning, therefore it is necessary to keep the growth moderately strong by root

pruning and by paying attention to summer pinching, so that little pruning is required in winter. Young trees, which have still much wall space to cover, should have as many shoots laid in as the case may demand and the shoots shortened back to a good wood bud. When selecting young trees for planting from the nursery, choose healthy two year old trees that have not been subjected to severe knife pruning. Good varieties for wall culture are Early Rivers, Frogmore Bigarreau, Governor Wood, May Duke, Black Tartarian, and Bigarreau Napoleon. The distance apart to plant is 16 feet or 18 feet, according to the aspect, east or west, and the natural richness of the soil. Morelle Cherries should also have attention in pruning and tying during this month; the work can be carried out more quickly in mild weather than when winter weather sets in.

APPLES AND PEARS.

The lifting, root pruning, and planting of these should follow, and be finished as soon as possible, as autumn is undoubtedly the best time for carrying out the work. The distance apart to plant must be governed by the soil and district. For standards of strong growing varieties, such as Bramley's Seedling, Newton Wonder, and Blenheim, 25 feet to 30 feet apart is none too much. Half standard Plums or other small fruits may be planted between. Large fruiting varieties, such as Warner's King, should have the most sheltered position, or the best fruits are often blown off and spoilt. Put a stout stake to each tree at the time of planting, and mulch them afterwards with light litter. Pyramids or bushes are the most useful form of trees to grow in a restricted garden. Pears on the Quince and Apples on the Paradise stock grow less vigorously, and may be planted 6 feet to 9 feet apart. They come into bearing early, and by careful summer pinching and periodical lifting or root pruning very little winter pruning is necessary. Deep planting must be avoided, the roots should be encouraged to keep near the surface by annual mulchings. By growing trees in this form, gathering and pruning give less trouble, and the vegetable quarters are not unduly shaded.

Impney Gardens, Droitwich.

F. JORDAN.

INDOOR GARDEN.

AZALEAS FOR FORCING.

WITH the great variety of other plants that naturally flower in the autumn it seems unnecessary to ruin the Indian Azaleas, that would render a much better account of themselves as decorative flowering plants during the latter part of January and later. Forcing, to have them in flower by Christmas, causes them to make weak growth, liable to be attacked by thrips. Azaleas of the small-flowered amena type are more suitable for early forcing, and these only should be used for the purpose. They are hardier, and after flowering they will bear rougher treatment; they are also more easily forced into flower. Before placing the plants in strong heat put them for a week or so in a close but low temperature to induce the flower-buds to swell; afterwards they will burst into flower very soon after being placed in heat.

EUPHORBIA JACQUINIEFLORA.

This should not be given a close temperature. It forms flower-buds more freely and makes a shorter-jointed growth in a temperature of 60° at night, with a rise of 5° during the day, air on all occasions being judiciously admitted. These plants do not root vigorously and stimulants are little needed, though weak soot water will impart a good colour to the foliage.

POINSETTIA PULCHERRIMA.

These are usually in small pots, and the soil should be kept moist or the leaves will soon turn yellow and fall off; especially is this true of plants that were propagated late. With a crack of air, a temperature similar to that recommended for Euphorbias, and a little weak soot water the bracts will open freely and maintain a bright colour.

LILIUM HARRISI AND L. LONGIFLORUM.

The bulbs should be potted up immediately to flower during the latter part of April and early in

May. They root freely during the winter, and thrive best in a mixture of lumpy fibrous loam, peat, and a little rough sand. The tips of the growths at this season are frequently attacked by green fly, which soon ruins the prospect of their flowering satisfactorily, and to keep it in check fumigate occasionally with XL All Vaperiser. Liliums of the lancifolium section, the growth of which has died down, should have all the old soil shaken away from the bulbs and again be repotted in a good rich compost consisting of lumpy loam and peat, or leaf-mould, cow manure, and sand. Place the pots containing the bulbs in a cool position where the soil will not dry too quickly, or plunge them in sand until growth begins to start.

J. P. LEADBETTER.

Tranby Croft Gardens, Hull.

KITCHEN GARDEN.

POTATOES.

Now that these are all under cover they should be inspected frequently. If they have been stored when damp diseased tubers are not so easily detected, and if left among sound tubers the latter soon become diseased also. Those intended for the table should be kept dark, and a quantity removed from the pit to meet requirements for a few weeks at a time. Those for seed may be placed on shelves exposed to the light, as they can be looked over frequently. New varieties may be got now, but it is a mistake to have too many sorts. Rather keep to those that are of good flavour and known to do well in the district.

JERUSALEM ARTICHOKE.

Part of this crop at least should be got up and stored in damp sand for use during the winter in case severe frost makes lifting difficult. It is not necessary to lift the whole crop, as they are quite hardy, and are even better left in the ground until spring, when the remainder may be lifted, the ground levelled, and replanting done in one operation. Globe Artichokes, if not already protected, should be attended to without delay. When the protecting material has been placed round the plants, some earth should be sprinkled on to prevent the lighter part of the covering being blown about.

TURNIPS.

These may now all be got up, except the Swede varieties, as they are much improved in flavour if left in the ground till frost comes. Let the crop be stored in a shed or against a north wall or other cool place. The roots should be left intact and the tops shortened to within half an inch of the bulb. A few may be left in the ground for use during the present mild weather. If the Carrot crop has not been lifted, it should be done at once, as these are easily injured by frost.

THOMAS HAY.

Hopetoun House Gardens, South Queensferry.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

QUALITY IN POTATOES.

[TO THE EDITOR OF "THE GARDEN."]

SIR, — IN THE GARDEN recently Mr. Egleheart expresses opinions on the above so utterly at variance with the experience of the majority of gardeners that I am tempted to trouble you with a note in reply. I have had no experience with the new varieties. Holborn Abundance, Windsor Castle, and Up-to-Date are quite good enough for me, the average yield is from 8 tons to 12 tons per acre, and we never have the slightest complaint as to quality. Some time ago a quantity of tubers of a French variety were received, and I grew them one season, but they were never asked for again. They were a pronounced yellow in colour and a consistency somewhat like soap. If a good floury Potato is so objectionable, perhaps Mr. Egleheart will explain why it is always in demand? Are ninety-nine out of a hundred palates so much in the

wrong that they do not know a good Potato? For this is practically the outcome of Mr. Egleheart's note. My memory carries me back, so far as Potato culture is concerned, to about the middle of the sixties, and right away from that time, when a white Forty-fold (a selection from the red) and the Scotch Regent were favourites down through the days of Paterson's Victoria, Schoolmaster, and Windsor Castle, the demand in all private establishments, whether large or small, has been for a good white floury Potato. Up-to-Date may be of indifferent quality on some soils. Here it is very good indeed, at least I know if I happen to run out of it and have to buy, the cry from the kitchen is always "Why don't you send the same kind of Potatoes as we have been having?"

Claremont, Esher.

E. L. B.

[TO THE EDITOR OF "THE GARDEN."]

SIR, — Mr. G. M. Taylor's object (page 318, THE GARDEN, November 5) cannot, unfortunately, be fully attained by instituting more competitions for cooked Potatoes at our (or any other) particular show. I wish it could. Only by cooking tubers of the same variety from different soils and at various periods can its true merits be learned. We are now getting a plebiscite of the best eating Potatoes, the result of which will appear in our annual report. The forms are now ready, and I shall be happy to send one to anyone who cares to give his opinion, whether a member of the National Potato Society or not. The fact of this being done will show that we are alive to the importance of the matter and doing our best to get reliable information.

Postling, Hythe.

WALTER P. WRIGHT.

DORYANTHES PALMERI AND OFFSETS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, — In your issue of June 18 (page 435) Mr. E. H. Woodall refers to Doryanthes Palmeri, and asks whether it produces offsets. It does produce offsets, though somewhat sparingly, at all events in Sydney. It is in flower in this garden at the present time. One plant flowered last year with the main flowering stem (covered with bracts) 9 feet long. Towards the end of this axis the flowers branched out. After flowering the axis continued to elongate for another 7 feet or 8 feet, and at the end of this it is now flowering as I have said. This obviously shows that when this plant first flowers the stem should not be cut, but the plant should be given an opportunity of flowering a second time.

J. H. MAIDEN.

Botanic Gardens, Sydney, September 24.

COLOUR IN THE GARDEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR, — The present season will long be remembered for the extraordinary colouring of the autumn foliage. For several years previous to 1902 the rainfall had been much under average, and vegetation, especially forest trees and shrubs, was beginning to suffer; indeed, many fine Beech trees in some parts of the country died, owing to the lack of moisture at the roots. Happily, however, we have no longer any anxiety on this score. We have had a plentiful fall of rain during the past two years, and now we have just passed through one which will be remembered for many years as being one of bountiful crops of all kinds. The outcome of all this is a wonderful colour effect in trees and shrubs. All those mentioned below have been most gorgeous in this country. The Acers are always striking at this season. The first to be noticed is A. colchicum rubrum, a valuable tree for various purposes. Next in order comes A. saccharinum; this has a little more bronze mixed with the bright yellow. Then we have the Norway Maple (A. platanoides), very beautiful at present. Coming to the smaller growing kinds, we cannot pass over A. Ginnala. It gives a fine bit of colour, only, however, for a very short time; the leaves soon fall. A. tataricum is a similar tree, and has the same fault. A. rufrum is magnificent, as fine as any Coleus one could find in the greenhouse. A. palmatum is

also just beginning to colour finely. So is *A. campestris*, our common hedge species; nothing is finer than this on the Cotswold Hills.

Leaving the *Acers*, we must mention *Parrotia persica* and the *Poison Oak* (*Rhus Toxicodendron*), both very rich. *Amelanchier canadensis* is most beautiful. *Rhus Cotinus purpurea* is a lovely tree for autumn effects, and so is *R. Osbeckii*. *Ribes speciosum* is a finely-coloured, low-growing shrub. *Liquidamba styraciflua* colours very beautifully. *Euonymus amurensis* (elata) is perhaps one of the most gorgeous low-growing shrubs one can find at this season. *Cornus Kousa* is fine. *Berberis Thunbergii* is, of course, indispensable for the front of the shrubby border, and *Cotoneaster horizontalis* is another beautiful plant for the front of borders.

These are a few of a very large number of shrubs and trees which at the present season make the countryside full of colour. Why people will continue to plant common Laurels, Box, Privets, and such like things I am unable to understand. True, they serve a very important purpose as screen plants. There is, however, no reason why a few of the above shrubs and trees should not be mixed in with these evergreens.

Cirencester.

T. A.

APPLE RIVAL AND OTHERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—On page 304 of *THE GARDEN* for the 5th inst. you say that Apple Rival was sent out by Messrs. Cheal. That is a mistake, as it was sent out by Messrs. Clibran, Altrincham. Messrs. Cheal sent out Armorer, Atalanta, and Paroquet; Messrs. Bunyard sent out Mrs. Phillimore; and the stock of Hector McDonald has passed into the hands of Messrs. Pearson and Sons, Nottingham, and will be sent out by them next year.

Welford Park, Newbury.

CHARLES ROSS.

APPLE LADY SUDELEY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—My experience of this variety is more favourable than that recorded by Mr. Crook (page 263), and I imagine our amount of moisture is equal to that at Forde Abbey, if not more so. Our trees of this variety are Espaliers, which give us some very fine fruit, and are on the Paradise stock. I had the pleasure of seeing the original tree of this variety in a garden at Petworth. When Messrs. Bunyard purchased the stock it was laden with fruit. This variety requires careful pruning. I wish I could speak as favourable of the other Midstone Apple. I am not altogether pleased with Allington Pippin.

Poltimore Gardens.

T. H. SLADE.

THE NATIONAL POTATO SOCIETY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—When we are told, on the authority of the Rev. G. H. Engleheart, that Potato Up-to-Date is only fit food for cattle and Sir J. Llewelyn is vapid and tasteless, I am led to wonder whether your correspondent has a suitable soil for Potatoes. Mr. Engleheart really attacks the Potato Society. He ignores the fact that it has not yet been a year in existence and that—apart from the recent show at the Crystal Palace, the primary object of which was to arouse more public interest in the Potato—the society has, at considerable cost, promoted no less than twenty trials of a dozen well-known varieties in diverse parts of the country, first, with a view to test the cropping merits of each variety; and, secondly, to ascertain, so far as possible, what effect diverse soils may have on flavour or table quality in each variety when cooked. Potato growers do know that in the production of flavour or its absence in the tubers soils play a most important part. To ask for varieties of raw Potatoes at a show, to be tested for flavour, would have been absurd; the environment would not admit of any such test. If, as is hoped, a large trial of varieties can be conducted at some central station on the society's behalf another year—say at Wisley or Rotherham—then the flavour or cooking test may be applied freely. It is not everyone who

knows that in relation to main cropping Potatoes there always has been since 1848 some subtle connexion between high flavour in Potatoes and the disease. We had in Victorias, Regents, Lapstones and some others, varieties of the highest table quality, but they decayed wholesale under the destructive influence of the disease. Under the circumstances that then prevailed we had to obtain real disease-resisting varieties first, and, whilst not one variety resists disease absolutely, very many do materially; hence to have secured such a fine race of Potatoes as now exists and which give us such huge, clean crops is great gain. But even now, the moment we admit into these strains any infusion of the yellow flesh, Ash-leaf, or other weak but good-flavoured varieties, then does disease become very prevalent. At all hazards we must keep a firm hold of what we have so far gained. The booming seen in a limited direction affects very few Potato growers only. The great mass of Potato merchants regard the Potato as an important article of food.

A. DEAN.

HEMEROCALLIS DR. REGEL.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Mr. Gumbleton does well to write so favourably of this Day Lily. I grow twelve sorts and consider this much the best of all. The intense golden orange colouring is the great attraction. The six petals vary in width, the three upper ones being $1\frac{1}{2}$ inches wide. The blooms altogether measure from 4 inches to 5 inches in diameter. It has a spike carrying the flowers well above the foliage.

E. M.

POLYGONUM BALDSCHUANICUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I grow this Polygonum in our strong soil with little trouble, but I notice that in a spell of dry weather its leaves quickly droop with hot sun. Directly the roots are well soaked it quickly regains its normal appearance. I therefore now supply the roots liberally with water in dry weather and the plant grows vigorously and flowers profusely. The first year planted I placed a 10-foot pole for its support, and it not only reached the top in a short time but it grew halfway down again. I have lately seen this plant trained up the supports and on the crosspieces of a pergola, but do not think this situation suitable to its growth, which is semi-weeping.

E. M.

LINUM ARBOREUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This pretty yellow Flax, which forms the subject of an interesting note by Mr. S. W. Fitzherbert in *THE GARDEN* of the 29th ult., is much harder than many suppose, although it does not appear to like a wet winter followed by severe frost in spring. I have seen it doing well and proving quite hardy as far north as Stirling, and I know that it stands the winter of Scotland still further north than that. It is difficult to choose between it and *L. flavum*, but one may well grow both of these pretty plants. So far as I have been able to learn, it is even harder in Scotland than *L. flavum*, and it is certainly much more common, if one may apply that term to a plant which is not too plentiful. As Mr. Fitzherbert remarks, *L. arboresum* rarely produces seeds, but *L. flavum* seeds freely, and self-sown plants are generally plentiful.

Carsethorn, by Dumfries.

S. ARNOTT.

TROPEOLUM AZUREUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In your issue for October 8 your correspondent "J. C." rightly says how seldom does one see the above in our greenhouses, and I may add how seldom does one get the true plant when ordering. We procured two bulbs from a trustworthy seed house in the autumn of 1901, and to our great dismay the following spring both bulbs turned out to be *Tropeolum brachyceras*, a yellow-flowered sort, that grows and blooms abundantly in the open in the south of France I am told. The seedman in question, upon being told of the disappointment,

kindly offered to replace them the following autumn, which he did, after telling the Continental firm who supplied the first bulbs that they were not true to name. This latter firm sent two more tubers to our seedsmen, and when they flowered this spring both turned out to be *Tropeolum brachyceras* as before, which, I need not say, was both disappointing as well as annoying. This autumn we have received two more tubers from the same source, as well as a pair from another firm, and hope to be able to chronicle better results after a third trial. I have also been told by a famous lady gardener that it is most difficult to get this *Tropeolum* true. As it is a weak grower, and slow of increase, this may partly account for inferior sorts being substituted. There is little to add to the treatment "J. C." advocates, except that as soon as growth begins thin twiggly pieces of Birch, or similar wood, be placed in the pot for the slender trailing shoots to cling to, or pieces of trellis trained near to the glass roof. This they soon take to, and show their flowers to great advantage. *T. tricolorum* grows very much stronger, reaching 15 feet or more. One small item should not be overlooked, and that is to keep a sharp look out for slugs and snails when growth commences or they will quickly devour the lot. Red spider appears their greatest enemy while in active growth, and we find light dewing overhead with the syringe morning and evening to be beneficial to the plants. Repotting should be done in July, before growth commences, or many are liable to get broken. A little weak manure water may be given from January onwards.

J. MAYNE.

SALVIA HORMINUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—*Salvia Horminum*, a native of the Mediterranean region, well merits the praise meted out to it by Mr. J. Crook on page 262. This year it was seen in good form at Castle Drummond, Perthshire, and Powerscourt, County Wicklow; it is there massed by hundreds in the flower gardens. On dry banks, in warm situations, it may be easily naturalised, self-sown seed springing freely. Around Edinburgh it occurs as a casual. I also saw this annual at M. Correvon's establishment at Geneva, where, together with *Coris nonspeliensis*, several species of *Vernonia*, and other interesting plants, it gave a good bit of colour in the fall of the year, as rough weather was setting in.

The coloured bracts, rather than the flowers, are the attractive portion of this *Salvia*, and as these remain in good condition over a considerable period it is desirable to get them on early. By sowing in heat in February or March good plants will be ready at the end of May for setting out at 8 inches apart. In the open sow in April. Plants gathered in their southern home are from 9 inches to 16 inches in height, the shoots terminating with six to a dozen bracts, each measuring from half an inch to 1 inch long. Under cultivation the bracts are much larger. The typical *Salvia Horminum* has purple bracts, but a form exists with red ones, and in another they are white. Does anyone in this country grow these two?

D. S. FISHER.

Royal Botanic Garden, Edinburgh.

POTATO AND WHEAT CROPS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Although only a farmer I take *THE GARDEN*, and I garden usually much more than 100 acres of Potatoes and more than that of Wheat; and, when I read the opinion of such men as Mr. A. D. Hall and Mr. E. Molyneux, I stand aghast, thinking that if others can make £12 and £35 per acre of Wheat and Potatoes respectively there must be something wrong in my management. I know of many abnormal prices when either of the articles are of a special kind or grown for seed, but over vast areas I am inclined to think that Mr. Hall's figures should be just halved, and £6 and £17 10s. would then be nearer the price that has been made the last few years. Prices of Wheat have, of course, been a little better lately, but $4\frac{1}{4}$ qrs. have not been grown nor 28s. been made on the average of the last few years. When, also, I see letters

and articles advising the eating Potatoes ("ware" we call them) to be carefully placed on the latticed shelves of the Potato houses we see in large gardens, I then think that gardeners do not know what good tubers are like, for I assure you they will not retain their quality if kept out of the pits more than a fortnight or so. The advice, too, that the diseased haulms ought to and must be burned is no doubt very good, or sounds so; but, given suitable weather and a tender variety of Potato, the all-pervading countless myriads of spores will attack the leaves, resulting in the present sad condition of the Up-to-Dates, which were smitten at the same period of warmth and moisture that sprouted sadly our Wheat and Barley in the stook. The very best Potato farmer on the very best Potato farm in the kingdom, when I saw it, was feeding 180 bullocks, and every morsel of haulm was saved for them to tread into manure for the next Potato crop. And no one grows sounder tubers.

The great Potato show at the Crystal Palace is no earthly use if held when everybody is taking up their tubers and no one knows how this or that sort has yielded or withstood the disease. If the society could take the minor hall at the Smithfield Show we should all put in an appearance, and we might then buy a few pounds of one boomed variety or 100 tons of another. NORTH LINDSEY.

NURSERY GARDENS.

MESSRS. W. WELLS AND CO.'S
CHRYSANTHEMUMS.

MESSRS. W. WELLS AND CO.'S large double-span greenhouse, 126 feet in length by 54 feet in width, is at the time of writing one of the finest sights within easy distance of the great Metropolis. The collection of Chrysanthemums is a remarkably comprehensive one, and the blooms of all the season's novelties are always produced in such a way as to enable the connoisseur to form a pretty accurate judgment of their capabilities in the future.

Novelties abound, many of them Continental, many of them home-grown seedlings, and others from our distant Australasian Colonies. There are some excellent examples of recent additions, which have proved worthy of a second, or even third, year's trial. Among them we note a fine batch of noble blooms of General Hutton, a grand Japanese of unusual dimensions, deep golden yellow, slightly tinted bronze. Miss Elsie Fulton is a noble white, already well known to the grower for show; and the more recent Mrs. J. Dunn is also conspicuous in a number of capital examples. Rich and attractive is W. R. Church, a massive broad-petalled Japanese that needs no recommendation, as its peculiar shade of crimson makes it everywhere an effective variety. William Duckham is a deep solid-looking variety with incurved florets, colour silvery pink; and other shades of varying intensity in this colour are represented by such varieties as Mrs. George Mileham, Mrs. Barkley, Countess Harrowby, &c. Among the very biggest is Mrs. White Popham, pale purple; and hard by is Florence Penford, a big Japanese with grooved florets, globular in form and deep in build, colour pale buff. Mrs. W. Knox, a fine deeply-built flower, close and compact, with intermingling florets, colour pure pale yellow, is also worthy of note. Miss Mildred Ware is now well known, and maintains its reputation for size and colour wherever we have seen it. Very fine are the noble examples of Mme. Paolo Radaelli, pale blush pink, a big solid flower peculiarly useful on the show-board. Mrs. Henry Weeks, Mme. Ferlat, and Miss Stopford are among some of the best of the whites.

Yellow is essentially the primary colour of our famous flower from the Far East, and, indeed, it is the colour most esteemed by the Chrysanthemum specialists of the Celestial Empire. A Chinese author, who wrote about Chrysanthemums in 1783, tells us that this colour is more highly appreciated than the others, and in his descriptive list he places the yellow kinds first. At Merstham among

the yellow varieties are many examples of the best novelties of recent introduction, the most striking and effective being Colonel Weatherall, Merstham Yellow, Mand du Cros, Chelton, the yellow sport from Miss Nellie Pockett, and another, a sport from Miss Elsie Fulton called Souvenir de Mme. Baron. Mrs. W. Duckham is also a grandly-built globular flower with medium-sized florets, in which the body colour is slightly tinted carmine. Bessie Godfrey has been seen everywhere in good form this season, and is certainly one of the finest in its form and shade, while Calvat's grand seedling, named after that champion grower Mr. F. S. Vallis, is one of the most popular of its kind.

A few others of various tones occur to us as worthy of a brief mention. They are Mrs. F. W. Vallis, which has long drooping florets, colour crimson, shaded apricot yellow, reverse old gold; Henry Perkins, a large bloom of great depth, florets long and drooping, colour bright red-crimson, reverse golden; W. A. Etherington, also of great size and of excellent form, colour flesh pink, shaded mauve; Leila Filkins, fine blooms of very deep build, close and compact, the florets intermingling, soft pinkish lilac-mauve.

Novelties of much more recent introduction abound, but our space will only allow of the most superficial mention, as they would form a sufficient

MR. GEORGE DINGWALL.

theme for a special article to themselves. Of these we like Valerie Greenham, a fine seedling of English origin, with medium-sized florets, colour lilac-mauve; Dora Stevens, long drooping florets curly at the tips, bright shade of rosy amaranth with straw reverse; Mrs. H. W. Partridge, florets of medium size, colour rich fiery crimson, old gold reverse; Hettie Wedge, Japanese, with florets grooved and incurving, colour lovely shade of golden amber; J. H. Doyle, the colour of this may be described as a salmon cerise with golden reverse, big fine blooms with long florets; Mrs. George Heaume, a fine novelty, globular and deep in build, the florets are of medium width, colour golden buff; E. J. Brooks has rather broad florets, blooms big and solid, plum-coloured amaranth; Mrs. J. E. Dunne, a grand flower of great size, florets long and drooping, colour salmon rose, passing to golden buff in the centre. C. H. P.

A WELL-KNOWN SCOTCH GARDENER.

MR. GEORGE DINGWALL.

In the course of this month Mr. George Dingwall, head gardener and forester to the Right Hon. Sir Henry Campbell-Bannerman, G.C.B., at Belmont

Castle, Meigle, N.B., leaves Belmont after a long period of service. Mr. Dingwall is a native of Ross-shire, and served his apprenticeship at New Tarbatt House, Parkhill, in that county, under the late Mr. James Laing, brother of the late Mr. John Laing of Stanstead Park, London, and, as Mr. Dingwall remarks, one of the best all-round gardeners he ever knew. In 1857 Mr. Dingwall left for the Lothians, where he was a journeyman for two years. In 1859 he went to East Bank Gardens as foreman, remaining there until November, 1860, when he left to enter upon his first appointment as head gardener. This was with Mr. John Hall Maxwell, C.B., Dargavell House, Renfrewshire. In 1863 Mr. Dingwall entered upon a similar appointment with Mr. G. Kelly McCallum, Braco Castle, Braco, Perthshire, where he remained until 1869, when he was appointed gardener to Mr. G. Stirling Home Drummond at Ardoch House, Braco. At Ardoch Mr. Dingwall laid out the gardens anew and made a new flower garden. To the successful carrying out of these works Mr. Dingwall largely attributes his securing his next appointment in 1886—that of gardener and forester to Sir Henry Campbell-Bannerman, who had recently purchased the estate of Belmont, Meigle. At Belmont Mr. Dingwall remodelled the whole of the gardens and grounds, and carried out the important works which have made Belmont such a beautiful and well-kept property. Mr. Dingwall has purchased a property at Newtyle, not far from Belmont Castle, where, it is to be hoped, he may long be spared to work. He does not intend to relinquish horticulture entirely, however, as he means to devote a part of his time to seed-growing. Some of his strains are already well known for their excellence, and he purposes to enter still more largely into seed-growing, as he has a greater demand for his stocks than he can meet. Mr. Dingwall is a most able all-round gardener, and the gardens at Belmont Castle show the evidences of high cultivation in every department. He takes great pleasure in landscape gardening, for which he has a special aptitude, and he has contributed papers of great ability upon this subject to meetings of such horticultural associations as that of Dundee, where he lectured last year. He has also frequently acted as judge at flower shows, where his services were highly esteemed. Among his other acquirements is that of basket-making, and he has taken prizes at industrial exhibitions for his handiwork of this kind, which is exquisitely done. He is a keen antiquarian, and a man full of interesting information on many other matters besides those connected with his calling. S. ARNOTT.

SOCIETIES.

REDHILL, REIGATE, AND DISTRICT GARDENERS' ASSOCIATION.

THIS society held its fortnightly meeting on Tuesday, the 25th ult., in St. Matthew's School, under the presidency of Mr. W. P. Bound, when a most interesting paper was read by Mr. C. J. Salter of the Gardens, Woodhatch Lodge, Reigate, on the "Zonal Pelargonium and its Culture." As usual there was a very large attendance, over 100 members being present. That the lecturer was thoroughly at home with his subject there was no doubt, judging by the very able manner in which he dealt with it. The introduction of the zonal Pelargonium was briefly touched upon; then followed notes upon striking the cuttings, potting, soil, temperatures, and the best houses. Many members took part in the discussion which followed. A hearty vote of thanks was accorded the lecturer, which brought the meeting to a close. F. C. L.

DULWICH CHRYSANTHEMUM SOCIETY.

THE eleventh annual exhibition of the Dulwich Chrysanthemum Society took place on the 8th and 9th inst. The society is in a most flourishing condition. The initiation of a summer show of Sweet Peas, &c., and the remarkable support given to it, especially by the amateur members, points to increasing interest in the neighbourhood. A capital programme of lectures for the winter session has been arranged. The first, by Mr. R. B. Leach, on "Begonias," on Tuesday, October 18, was of a most interesting character, the various stages of Begonia culture, from the initial difficulties of seed fertilisation to the finished and dried-off tubers, were practically and minutely described. The peculiarities of various types were referred to. The hearers were greatly interested and instructed, and the questions which followed the paper were answered in a manner which can only come from a life-long intimacy with the subject.

Later papers on "Sweet Peas," by Mr. C. H. Curtis; "Horticulture in Canada," with lantern, by Mr. Cheal; "Members and their Gardeos," &c., are included in the programme.

SOUTHAMPTON ROYAL HORTICULTURAL SOCIETY.

"BETTER than ever" was the universal verdict in connexion with the exhibition of Chrysanthemums and autumn fruit held by the above society on the 2nd and 3rd inst., in the spacious building known as the Skating Rink, the entries being at least 100 in excess of any previous year. The large hall, 130 feet by 90 feet, proved hardly large enough, and it taxed the ingenuity of the secretary to provide space for all the exhibits.

There was a slight falling off in the number of cut blooms, but the plants made a much more imposing array than usual. The best collection of Chrysanthemums in pots was shown by Mr. C. Halsey, gardener to J. C. E. D'Esterre, Esq., Elmfield, Southampton, his group being well arranged, and most of the blooms were fit for any exhibition board, the plants ranging from 18 inches in the front to 6 feet at the back. The same exhibitor secured the first for four plants suitable for conservatory decoration. Mr. B. Henley, florist, of Woolston, being second in the first-named; and Mr. C. Dymott, florist, Millbrook Road, in the latter. Some immense bush plants were shown, Mr. Dymott being first, and Mr. Halsey second. Two more competed in each of the above. The amateurs' groups were also very good, Mr. F. Chandler winning the first prize, in addition to a silver medal and the Mazawattee Challenge Cup.

The five mixed groups, Chrysanthemums arranged with other flowering and foliage plants, were the best ever seen at the autumn shows. The first, exhibited by Mr. E. Willis, Winchester Road Nurseries; and the second, put up by Mr. T. Hall, gardener to Sir Samuel Montagu, Bart., South Stoneham House, being especially bright and effectively arranged; third, Mrs. Ubbell.

CUT FLOOMS.

This section comprised 130 vases, three to five blooms in each and about 400 blooms on boards. In the principal class, thirty-six Japanese, twelve varieties, in vases, Mr. George Hall, gardener to the Dowager Lady Ashburton, Milchet Court, was placed first, thus winning the Victorian Challenge Trophy for the fourth time in succession. His collection contained some very fine blooms, remarkable for their freshness. The best were Bessie Godfrey (premier bloom in the show), Miss M. Ware, Mme. P. Radaelli, G. Mileham, J. Dunn, and F. S. Vallis. Second prize went to Mr. B. Hollis, gardener to Major Chichester, Embley Park, Romsey; third, Mr. L. Dawes, gardener to Mrs. Ogilvie Hambleton.

For six white Japanese, two varieties, Mr. George Hall was first, with Mrs. J. Lewis and Mme. C. Nagelmaker; Mr. L. Dawes being a close second, with Mme. G. Henry and Miss A. Byran; the third going to a very successful amateur at this show, Mr. F. Chandler.

For six Japanese, any other colour, two varieties, Mr. G. Hall was again first with grand blooms of Bessie Godfrey and F. Vallis; Mr. B. Hollis securing second. Six others competed.

In the class for eighteen blooms, not more than three of a variety, Mr. H. Pearce, gardener to Mrs. Tragett, Awbridge Dunes, Romsey, was first, with flowers very little behind the first in the cut class, the best being F. S. Vallis, Ethel Fitzroy, Mrs. E. Mitcham, and Mrs. J. Lewis; second, Mr. A. J. Marsh, gardener to M. Hodgson, Esq., Morton House, Kingsworthy, who had some wonderful blooms of Sensation and Exmouth Rival; third, Mr. F. Chandler; and fourth, H. E. Sugden, Esq.

Incurved flowers were not largely shown, but those from the gardens of M. Hodgson, Esq., were very fine both in the vase and board classes, including C. H. Curtis (premier incurved in the show), Baron Hirsch, Mme. D. Marnet, Miss V. Foster, Paton Ralli, Edith Hughes, and Mme. Zerlat. The amateur vase classes were very meritorious, Mr. Chandler and Mr. Love, of Cowes, showing the best blooms.

In the class for two vases, single Chrysanthemums, Mr. George Elwood, gardener to W. H. Myers, Esq., Swanmore Park, secured first, with an effective arrangement; Major Chichester being second. Five others competed.

The exhibits in the class for twenty-four blooms were not so numerous as usual, but the three stands put up were all good. Mr. George Hall, Milchet Court Gardens, secured first prize. The following were very fine blooms: Bessie Godfrey, Mme. Nagelmaker, Mrs. H. Weeks, George Penford, Beauty of Leigh, J. S. Silsbury (grand), Ethel Fitzroy, and Countess of Hassorby. Second prize, Major Chichester; third, Mrs. Ogilvie.

There were several classes for twelve blooms of Japanese and one for incurved, the following being most successful: Lady Ashburton, Major Chichester, Mrs. Ogilvie, and M. Hodgson, Esq. There was also some strong competition in the classes open to amateurs and cottagers, the most successful being Mr. F. Chandler and Mr. J. Love. The first-named also secured the subscription challenge cup.

MISCELLANEOUS DIVISION

Palms, table plants, and Begonias were all shown well, the last-named making a very bright display.

Bouquets were more than usually numerous. Those from Messrs. Perkins and Sons, Coventry, were very beautiful, composed almost entirely of Orchids, and easily secured the first prize both for ball and bridal.

For table decoration (Orchid excluded), Mr. George Elwood, Swanmore Park Gardens, was deservedly first, with a pretty arrangement of single Chrysanthemums, sprays of Ampelopsis, Veitchii, &c.

FRUIT.

The wonderful display of fruit was, no doubt, the special feature, comprising eighty bunches of Grapes and nearly 700 dishes of Apples and Pears, and the whole, with the exception of two trade exhibits, were the produce of the home county. As Mr. Challis, one of the judges, remarked at the luncheon, "it was doubtful whether any other county in England could produce such a display as they had seen that day: certainly not with Grapes, and the wealth of colour on the Apples was remarkable."

For three varieties of Grapes, Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Chilworth Manor, was first with fine

bunches of Mrs. Pince, Muscat of Alexandria, and Black Alicante; Mr. O. Eastwell, gardener to L. Walker-Munro, Esq., Rhinfield, Brockenhurst, was second with bunches only a point or two behind, showing Aluwick Seedling, Muscats, and Lady Downe. Three others competed.

In the class for two bunches of Black Alicante, Mr. Eastwell was placed first with a beautifully finished bunch of medium size, Mr. Bowerman, gardener to Lord Bolton, Hackwood Park, being second, and Mr. J. Hughes, gardener to A. P. Ralli, Esq., Twyford Lodge, third. There were five other competitors.

For two bunches, any other variety, Mr. Fleming was an easy first. For two bunches of white the prizes were awarded in the same order as in the three varieties. The best single bunch of white was shown by J. W. Fleming, Esq., and the best single bunch of black by A. P. Ralli, Esq.

For four dishes of dessert Apples there were twenty-one entries, the first prize going to Mr. T. Hall, gardener to the president, Sir Samuel Montagu, with King of Pippins, Ribston, Allington, and Cox's Orange Pippin, the second and third going to Mrs. Ansteth Thicket, Bishop's Waltham, and W. H. Myers, Esq. There were several other classes.

Pears were represented by nearly sixty dishes. In the class for four dishes, Major Chichester was placed first with Marie Louise, Beurre d'Or, President, and Ormanville, and also took first for a single dish with Piton Duchessa. Sir Samuel Montagu was second in the former, and Lord Bolton in the latter.

VEGETABLES.

We always expect to see good vegetables at Southampton, and were in no way disappointed on this occasion, the whole of the twenty collections staged being of excellent quality. In the society's open class Mrs. Tragett was placed first, Mrs. Maltby second, and H. E. Sugden, Esq. (gardener, Mr. W. Valentine), third. Mr. H. Lee of Gosport had the best collection in the amateurs' and cottagers' class. For Messrs. Toogood and Sons' and Messrs. Carter and Co.'s special prizes Mr. Bowerman, gardener to Lord Bolton, Hackwood Park, staged grand specimens, and secured first in each class, Mr. Elwood, Swanmore Park Gardens, being second for the former, only a point or two behind Mr. Bowerman; A. Searl, Esq., Bassett, being second in Carter's class.

Messrs. Toogood and Sons, the King's seedsmen, Southampton, presented the following medals: Silver medal for the best collection of vegetables in the show, exhibited by a gentleman's gardener. Won by Lord Bolton. Silver medal for the best collection of vegetables in the show, exhibited by an amateur. Won by Mr. H. Lee. Silver medal for the best collection of vegetables in the show, exhibited by a cottager. Won by Mr. H. Broom. Silver medal for the best Carrot in the show. Won by W. H. Myers, Esq.

NON-COMPETITIVE EXHIBITS.

Amongst these we must give pride of place to the magnificent collection of fruit exhibited by J. W. Fleming, Esq. These were artistically arranged by Mr. Mitchell with small plants and coloured foliage. Mr. Mitchell staged, in addition to the fruit, a splendid collection of vegetables, consisting of twelve varieties. Sir Samuel Montagu, Bart. (gardener, Mr. T. Hall), also staged sixty dishes of fruit, for which he was awarded the society's silver medal.

Sir S. Montagu and W. Garton, Esq., Roseland, Woolston (gardener, Mr. J. Martin), each lent a large number of Palms and other decorative plants, which added greatly to the general effect of the show, for which they were accorded a vote of thanks.

The following also contributed extra exhibits: Messrs. Toogood and Sons, Southampton, Potatoes, bulbs, &c. (silver-gilt medal). W. H. Rogers and Sons, Limited, Red Lodge Nurseries, collection of fruit, &c. (certificate of merit). B. Ladham, Limited, Shirley Nurseries, perpetual Pinks, hardy plants, flowers, &c. (certificate of merit). Jarman and Co., Chard, Somerset, sixty dishes of fruit, &c. (certificate of merit). P. H. Cousens, fruit grower, Swanwick, Southampton, fifty dishes of fruit, &c. (certificate of merit). Charles W. Bredmore, seedsman, Winchester, fruit, Potatoes, and cut flowers (certificate of merit). J. Peed and Sons, Rongel Park Nurseries, Norwood, collection of fruit (certificate of merit). E. Willis, Winchester Road Nurseries, floral devices (certificate of merit), miscellaneous exhibit. C. Dymott, Freemantle Nurseries, Southampton, group of Chrysanthemums (highly commended). T. Tyler, Waterloo Nurseries, Freemantle, Begonias, Ferns, &c. (vote of thanks). W. Wells and Co., Limited, Earlswood, Redhill, Chrysanthemum novelties (certificate of merit). F. Cozens, Rownham, Dahlias (vote of thanks). A. Maple, Nursling, miscellaneous exhibit (vote of thanks). H. Longster and Co., Southampton, miscellaneous exhibit. W. Palmer, Andover Nurseries, new seedling Apple, new double Primula. R. S. Ekliss, Esq., Bittern Park, Apples (award of merit for new seedling Apple). Perkins and Sons, Coventry, standard cross (very highly commended). J. Ambrose, F.R.H.S., Cheshunt, Herts, black Grane Melon C. stable (first-class certificate), and Beckwith's Carnations, which attracted much attention.

AT THE LUNCHEON

Mr. Challis said, in congratulating the council on the show, "I also congratulate your secretary on the excellence of the arrangements. I am in the habit of visiting many shows, but nowhere do I find such completeness and method as I find at Southampton."

CARDIFF SHOW.

THE annual autumn display was held, as usual, on the 2nd and 3rd inst. in the Park Hall, which was taxed to its utmost to contain the exhibits entered. It was a grand display, and reflected much credit on all concerned, especially Mr. H. Gillett, the energetic secretary, who had all the arrangements well in hand. Cut blooms were a strong feature. The leading class was for eight vases of Japanese varieties, three blooms in each. The Thomas Andrews Challenge Cup, with a liberal cash prize, was offered in this class. Mr. W. Drake, 44, Cathays Terrace, Cardiff, was again successful,

securing the coveted award with handsome blooms of the following varieties: Mme. Paolo Radaelli, Bessie Godfrey, Mrs. J. Lewis, Mrs. F. W. Vallis, and Henry Perkins as the leading blooms. Mr. John Duff, gardener to Mrs. Wilkins, Bryn Glas, Newport, was second with heavy blooms; Mr. W. Iggulden, Frome, a close third. No fewer than ten competed for twelve Japanese. Mr. Duff was here successful with heavy, richly-coloured blooms of popular sorts; Mr. Iggulden was a close second. Mr. Drake had the best stand of twenty-four incurved, large, neatly-finished examples of popular sorts; Mr. Bible, gardener to Prince Hatfield, Draycot Park, Chippenham, second.

Mr. Allen, Penarth, won the Courtis Cup for twenty-four Japanese, while Mr. A. F. Hill easily won premier honours for twelve Japanese, and in a similar class for the Empire Challenge Cup Mr. Hill asserted his superiority quite easily, as well as for six, any variety other than white, with really fine examples of Mme. Paolo Radaelli. Single-flowered kinds were well shown in six varieties in vases by Mr. T. Bindon, gardener to Dr. T. Wallace, Cardiff.

Bouquets and wreaths were extremely fine, Mr. W. Treseder, Cardiff, securing most of the prizes. Mr. Bindon had the best trained plants, as well as those naturally grown. Messrs. G. Williams and Son had the best Chrysanthemum group.

Orchids were well shown by Mr. C. Brooke, gardener to — Gratte, Esq., 83, Commercial Road, Newport, and Mr. W. Carpenter, gardener to J. Buckley, Esq., the former winning for six, and the latter for three specimens. Gold medals were awarded to Mr. Busham for a collection of fruit, and to Mr. W. Treseder for Dahlias; and a silver medal to Messrs. Cypher for Orchids.

WINDSOR CHRYSANTHEMUM SHOW.

AS usual, the annual autumn show was held in the Albert Institute on the 4th inst., and was quite a success. The leading class for cut blooms was that for twelve Japanese and twelve incurved: three competed for the silver challenge cup offered. Mr. G. Lane, gardener to Miss Ridge, Englefield Green, was the winner with heavy Japanese and good incurved blooms, all well displayed. Mr. J. Mioty, gardener to Sir D. Gooch, Clewer Park, Windsor, was second.

Japanese blooms, arranged in a space of 5 feet by 3 feet, received four entries. Mr. Heaver, gardener to Miss E. Goodlake, Denham, was first with fine blooms, but lacking in arrangement; second, Mr. Lane. Incurved sorts were best shown by Mr. Lane, who won for two dozen blooms in eighteen varieties, and also for six, any one sort, with typical examples of C. H. Curtis.

Six blooms, any one Japanese variety, were strongly represented. Mr. J. Elkington, gardener to Owen Tudor, Esq., Old Windsor, was first with Bessie Godfrey in grand condition; second, Mr. Mioty, with Duchess of Sutherland in true character.

Twelve Japanese blooms, arranged in a basket or vase, were asked for, and brought a good entry. Mr. H. Hearn was first with well-built flowers of popular varieties. Single-flowered kinds were best staged by Mr. W. Cole.

Mr. Page of the Dropmore Gardens, Maidenhead, was a successful exhibitor.

The best group of Chrysanthemums was arranged by Mr. W. Cole, gardener to Miss E. B. Foster, Clewer Manor. Mr. Lane had the best group of miscellaneous plants.

HEREFORD FRUIT AND CHRYSANTHEMUM SOCIETY.

WITH respect to Apples, at least, the show held on the 2nd and 3rd inst. in the Shire Hall was a record one for Hereford, on no previous occasion have the classes been so well filled with fruit so generally excellent in every way. Grapes were remarkably good, especially the Lady Downe's Seedling staged by Mr. Grindrod. Pears, vegetables, and Chrysanthemums were also shown in good condition. All available space in the hall and the ante-rooms was occupied by the exhibits. The arrangements were perfect, but must have taxed the powers of even the able secretary, Mr. E. S. Jones.

Pears, twenty-four dishes: There were two exhibitors in this class, the leading collection coming from Mr. Humphries, gardener to the Earl of Chesterfield, Holm Lacey; Mr. Jones, gardener to H. L. Lutywche, Esq., Kynaston, was second. Dessert Pears, twelve dishes: Here, Mr. W. C. Hyde, gardener to W. Maynard, Esq., Holt, Ledbury, took the lead; Mrs. Bashill, Bridge Sollars, Hereford, followed closely. For eight dishes there were nine exhibitors. Here Mr. Foster, gardener to the Rev. H. Brierley, Bridston, was placed first with capital fruits; Mr. Grindrod was a good second.

Apples, fifty dishes, not more than twelve, or less than five fruits in each dish: There was very keen competition in this class, in which six exhibitors staged very fine collections. Mr. Watkins, Pimond Farm, Withington, was placed first, and had the largest and slightly the best coloured fruit, though his rivals, the King's Acre Nursery Company and Mr. Whiting of Credenhill, who were respectively placed second and third, followed very closely, each staging splendidly grown examples of the best varieties; Mr. Roe, gardener to E. W. Caddick, Esq., Caradoc Ross, was awarded an extra prize. Mr. Grindrod, gardener to G. T. Bates, Esq., Whitfield, Hereford, was the leading exhibitor of thirty dishes, and arranged a good selection. The second place was taken by Mr. W. E. Hyde.

Twelve culinary and twelve dessert varieties attracted six exhibitors, whose collections were of an even character. Mr. W. Jones, gardener to C. W. Hazelhurst, Esq., Moreton Court, was placed first; Mr. Wootton, Byford, and Mrs. Bashill were respectively placed second and third. The class for eight dishes of dessert varieties was closely contested by eleven exhibitors, among whom Mr. J. E. Jones secured chief honours; second, T. Llanwarne, Esq., and third, Mrs. Bashill.

Dessert Apple, Cox's Orange Pippin, was shown twenty times, Mr. Roe being first with large brilliant fruit; second, Messrs. Campbell and Gettings. Ribston Pippin was best shown by Mr. Watkins, followed by Messrs. Campbell and

Gettings amongst eighteen dishes. Messrs. Fewtress Brothers won with Blenheim Orange, and Mr. W. E. Hyde was second, thirteen dishes being staged. Amongst eighteen rivals Mr. C. Thomas led with King of the Pippins. Mr. Hyde being second. C. W. Radcliffe Cook, Esq., was placed first, with Worcester Pearmain, followed by Mr. Watkins among seven-teen exhibitors.

Kitchen Apples, Bramley's Seedling, brought Mr. Thomas again to the front, with Mr. Watkins following, while Messrs. Campbell and Gettings and Mr. Thomas were respectively first and second amongst nineteen exhibitors, with Lane's Prince Albert. There were fourteen entries for Peasgood's Nonsuch, the leading position being taken by Mr. Grindrod, and the second by Mrs. Bashill. Thirteen dishes of Newton Wonder were shown, Messrs. Roe and Grindrod taking respectively first and second places with grand dishes. For any new Apple introduced during the last seven years, seven dishes were staged, Mr. Whiting being first with King's Acre Pippin; Mr. Watkins second, with Lord Hindlip; and Mr. Roe third, with Caradoc Scarlet.

Pears: Nine dishes of Marie Louise were staged, the best coming from Mrs. Bashill. Mr. Humphries was a good first with Doyenne du Comice. Ten dishes of Pitmaston Duchess were shown, the Rev. G. H. Davenport, Foxley (gardener, Mr. Cume), being placed first.

Champion classes: For the best bunch of Grapes Mr. Grindrod won with a remarkably fine one of Lady Downe's Seedling. Rarely is this Grape seen in such grand condition. Dish of dessert Apples: Mr. Roe was deservedly awarded the prize with splendid fruits of Cox's Orange Pippin. Dish of culinary Apples: Mr. C. Thomas, with a perfect one of Bismark, was the winner. Mr. Powell, Warham Farm, had the best dish of Cider Apples, and staged Kingston Black.

Collection of fruit, six dishes: Here Mr. Grindrod won an easy first: Mr. Froggatt, gardener to J. Walker, Esq., Belmont, was placed second, and J. Corner, Esq. (gardener, Mr. Williams) third. Five excellent entries were staged in a class for Gros Colmar Grapes, Mr. Tanott, gardener to A. W. Foster, Brackhampton, being first; Mr. Talbot, gardener to Sir G. Cornwall, Moccas Court, second.

Prizes offered by Mr. Wilson, seedsman, Commercial Street, Hereford, for a collection of ten varieties of vegetables. This class was keenly contested, and Onions, Potatoes, Leeks, Celery, Carrots, Parsnips, Beetroot, Cauliflower, Tomatoes, &c., were splendidly staged, Mr. Grindrod being the leading exhibitor.

The only group of miscellaneous plants, which was an exceedingly creditable display, was arranged by Mr. Cox, gardener to Sir J. Cotterell, Garmons. Mr. C. Whiting, White Cross Nursery, Hereford, was the leading exhibitor, with a group of Chrysanthemums. The leading exhibitors of vases and other blooms of Chrysanthemums being Mr. Sampson, gardener to Mrs. Hope, Whitney Court, Mr. Humphries, and Mr. Tanott.

READING AND DISTRICT GARDENERS' ASSOCIATION.

"The Naturalisation of Plants and Bulbs on Grass" was the title of a paper read by Mr. G. Stanton of Park Place, Henley-on-Thames, before a large attendance of members. The president, Mr. Leonard Sutton, presided. Mr. Stanton in his opening remarks referred to the charm imparted to the half-kept pleasure grounds, woodland walks, and the nooks and corners that abound in most gardens by the naturalisation of plants and bulbs. He credited Mr. William Robinson as having done more for this movement than anyone in the country. In commencing this style of gardening, lessons should be drawn from the way some of our wild flowers cluster together in shade, partial shade, open positions, dry and moist situations. The most suitable plants for various positions were recommended, such as coloured Primroses, Polyanthus, Violets, Foxgloves, Hellebores, German Irises, Dandelions, Forget-me-nots, Yuccas, Spiraeas, &c. As to bulbs, much thought and care should be devoted to selecting the best and most suitable positions. Daffodils were specially recommended, and the varieties most adapted for the work were named. Different methods of planting were explained at some length. In conclusion the lecturer said that we were much indebted to the great natural garden at Kew for many lessons and much valuable information on the subject. A good discussion followed, in which the president, the Rev. Canon Fowler, and Messrs. Barnew, Powell, Tunbridge, Howlett, Neve, Dore, Cox, and Lever took part.

The exhibits were of exceptional merit. Mr. F. Bright, The Gardens, Whiteknights, staged a remarkable exhibit of Sutton's Discovery Potato, namely, 52lb., which he had produced from one tuber 1oz. in weight. Mr. W. Wilson, The Gardens, Lower Redlands, set up a splendid collection of Apples and Pears, consisting of about two dozen varieties.

Letters respecting the British Gardeners' Association were placed before the members, and after the subject had been discussed a proposition that the correspondence lie on the table for three months was carried unanimously amid acclamations. A vote of thanks to the lecturer and exhibitors brought a very pleasant evening to a close. Several new members were elected.

WEYBRIDGE.

The Parish Hall was taxed to its utmost to contain the exhibits arranged here for the autumn show, which was a great success. Cut blooms were numerous and good. The leading prize was a Japanese silver cup for twelve Japanese blooms, distinct, and for which seven entered. Mr. J. Lock, gardener to Sir C. Swinfin Eady, Outlands Park, was the prize-winner with a stand of heavy bright blooms of popular varieties. F. S. Vallis, Mme. Nagelmaker, Mrs. G. Mileham, and Mrs. F. W. Vallis were well represented. Mr. T. Stevenson, gardener to E. Mcatta, Esq., Addlestone, was a good second with smaller yet high-class flowers. Mr. H. Buckmaster, gardener to F. W. Smith, Esq., won the premier award for twelve vases of Japanese, three blooms in each; a capital exhibit. Mr. W. Shorte, gardener to Mrs. Machin, was a close second, both staging popular varieties. Mr. Lock won for eighteen Japanese and twelve incurved, as

well as for the best display in a tray 3 feet by 2 feet 6 inches with foliage of any kind. This last was an effective exhibit, showing how well under proper treatment large Japanese Chrysanthemums lend themselves for decoration.

Single-flowered varieties were quite a feature, and so were the Pompons, so well they were staged. Mr. Pagram, gardener to J. Courtenay, Esq., Weybridge, won the premier award in the former section, staging well-formed, richly-coloured blooms of Eureka, Edith Pagram, Grace, and Mrs. Walton. Mr. Caryer, gardener to W. G. Meisner, Esq., Weybridge, in the latter had beautifully developed blooms, not too large but shapely, of Mlle. Elise Jordan, Mlle. Marthe, President, and W. Westlake. Amateurs were well represented by Mr. Wheatley, Thames Street, Weybridge, who staged twelve Japanese blooms of a high order of merit.

Orchids were well shown by Mr. E. Watford, gardener to A. Hertman, Esq., Weybridge. Cattleya labiata, Oncidium Rogersii, and O. varicosum Rogersii were well flowered. Salvia, Begonias, Solanums, Primulas, and table plants were all well represented, and so were fruit and vegetables. Space, however, does not admit of a further mention of the classes separately.

BECKENHAM HORTICULTURAL SOCIETY.

LECTURES AND MEETINGS.

NOVEMBER 25.—"Vines and Peaches," by Mr. J. W. Barks. December 9.—"Popular Horticulture," by Mr. W. Torney. December 16.—"Alpine Gardening," by Mr. Edward Lovett (illustrated by lantern slides). 1905: January 6.—"Decorative Chrysanthemums," by Mr. P. Waterer. January 20.—"A Chat About Potatoes," by Mr. H. J. Jones. February 3.—"Horticulture in Egypt and Syria," by Mr. J. Cheal (illustrated by original lantern slides). February 17.—"The Management of Young Fruit Plantations and Inter-cropping," by Mr. S. Deadman. March 3.—"Bottling Fruit" (illustrated), by Mr. R. B. Leach. March 17.—"Hardy Flowering Plants of the Spring Garden," by Mr. M. E. Mills. March 31.—"Forced Vegetables," by Mr. W. A. Cook.

The library at the Church House, Beckenham, contains upwards of 500 volumes on horticulture (catalogues may be had on application), with seven of the weekly magazines on gardening. The reading room is open every Friday evening from 7 to 9.30 p.m.

MAUD HORTICULTURAL SOCIETY.

THE annual meeting was held in the Victoria Hall, Maud, recently, the Rev. W. Cowie, vice-president, in the chair. The financial statement, submitted by the treasurer, Mr. Smith, showed an income of £74 7s. 7d. and an expenditure of £65 4s. 9d., leaving a balance to the credit of the society of £9 2s. 9d. The statement was approved of, and it was agreed to continue the operations of the society. The retiring office-bearers were reappointed. Mr. John Michie was appointed a member of committee in place of Mr. A. Dempster, who retires from the committee this year.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE monthly meeting of the Scottish Horticultural Association was held in Dowell's Rooms, George Street, Edinburgh, on the evening of the 1st inst. The chair was occupied by Mr. R. W. E. Murray, Blackford House, one of the vice-presidents of the association, and there was a large attendance of members. A number of exhibits were shown, and four certificates were awarded. These were cultural certificates to Mr. M. Todd, for Roses, shown in a vase; to Mr. W. W. Lamont, gardener to the Rev. R. M'Nair, Colinton Road, for excellent Chrysanthemums; to Mr. Pirrie, Dalhousie Castle, for Cattleya Portia; and to Mr. David Lorne, for Potatoes, these being Northern Stars. Among the other exhibits were an excellent dish of St. Joseph Strawberries from Mr. T. Leslie, Trinity Cottage; fine Chrysanthemums from Mr. James Fraser, Kirravock; and early Chrysanthemums from Mr. Todd. The paper of the evening was contributed by Mr. W. W. Lamont, and was on the seasonal subject of "Chrysanthemums Mainly for Exhibition." As might be expected from a grower like Mr. Lamont, it was a highly practical and valuable one, although, of course, many points familiar to good growers were touched upon. It could not fail, however, to be of great value to many present, and was interesting to all growers of the Chrysanthemum. Mr. Lamont dealt principally with growing Chrysanthemums for exhibition, and, among other points, laid great stress upon the necessity of having the varieties exhibited up-to-date. The cultivation of Chrysanthemums for exhibition was well described, one question upon which emphasis was laid being that of the best places for growing plants. Mr. Lamont considered that the environment was of even greater importance than the individual who grew them; and in touching upon this he took occasion to support the action of the council of the association in offering prizes at the annual Chrysanthemum show confined to growers within the municipal boundaries of Edinburgh and Leith. He considered that growers in or near large towns were at a great disadvantage compared with those in the country. A reference was also made to the future of the flower, and the lecturer was strongly of belief that the day when the Chrysanthemum would no longer be cultivated would never come. A most interesting discussion followed, and Mr. W. W. Lamont was heartily thanked for his excellent lecture. The annual Chrysanthemum show of the association takes place in the Waverley Market, Edinburgh, on the 17th, 18th, and 19th inst., and there is every prospect of a magnificent display.

DUNDEE HORTICULTURAL ASSOCIATION.

The usual monthly meeting of the Dundee Horticultural Association was held in the Technical Institute, Dundee, on the evening of the 1st inst. There was an excellent attendance, and the paper of the evening was listened to with keen interest. The lecturer was Mr. Charles Comfort, Broomfield, Davidson's Mains, Midlothian, his subject being "The Gardener's Education and General Equipment." Mr. Comfort

treated his subject in a very able way, and few of the papers read to the members of this association have been so well calculated to inspire in the minds of the younger members a desire for improvement in their calling. He urged upon his hearers the desirability of improvement in their work and methods, and pointed out several ways in which this could be done. Mr. Comfort has evidently a high ideal of the equipment of a truly successful gardener, and he pointed out, among other things, the necessity of his having some knowledge of science and art, and of taking advantage of the opportunities of the winter evenings for attending classes and reading horticultural works. The advantages of visiting other gardens were also pointed out, and a thoroughly useful and suggestive lecture was given. Mr. Comfort was very heartily thanked. The next lecture of the course on the syllabus is on "Our Cone-bearing Trees," with lantern illustrations. The lecturer is Mr. J. E. Corr, Dundee, and the date is December 6.

EASTBOURNE CHRYSANTHEMUM SHOW.

THE Floral Hall, Devonshire Park, is an ideal building for a Chrysanthemum show, resembling, as it does, a large conservatory, and no better display has been seen at Eastbourne than that on the 3rd and 4th inst. The cut flower classes were filled throughout with first-class flowers, although in some instances lacking somewhat in freshness, having done duty the previous two days at Brighton.

In the open classes leading prize winners were as follows: For twenty-four Japanese blooms in not less than eighteen varieties, Mr. A. Simmons repeated his Brighton success, closely followed by Mr. J. Pitts, gardener to Mr. E. Ascheron, Charing, Kent.

Mr. A. Simmons also secured first prize for twelve Japanese. Mr. A. Wilson, gardener to the Marquis of Abergavenny, was second.

Six Japanese yellow or white in a vase with foliage or berries: First, Mr. G. Whitehouse, gardener to Mr. C. Diplock, Polegate. For the same number in any other colour: First, Mr. A. Wilson.

Table decorations were a good feature. Mr. G. Grigg, gardener to the Earl of Ashburnham, brought the best table of Orchids, arranged with Ferns, &c.

In the open fruit classes Mr. F. W. Thomas, Wannock, was first for both culinary and dessert Apples, Mr. G. Grigg taking like honours for stewing and dessert Pears, and also for three bunches of black Grapes; Mr. W. Allen, gardener to Lord Brassey, Normanhurst, winning for three bunches of white Grapes.

In the second division open to members the principal winners were the following: Eighteen Japanese, distinct: First, Mr. C. J. Dicker, gardener to the Hon. Miss Canning, Frant Court; second, Mr. E. Hopkins. Twelve Japanese, distinct: First, Mr. C. J. Dicker.

For six incurved, distinct: First, Mr. G. Grigg, who likewise took similar honours for a table of plants arranged for effect, and other prizes Mr. W. Ereach won for a collection of Potatoes; second, Mr. A. Brown.

Non-competitive exhibits were staged by Mr. G. T. Scott, Eastbourne, who had a large group of plants, flowers, &c., as also had Mr. Durrant Young of Eastbourne. Messrs. W. Wells and Co., Redhill, had some flowers of new large-flowered Japanese Chrysanthemums.

Mr. M. T. May, gardener to the Duke of Devonshire, had a large display of plants, &c., tastefully arranged. Mr. J. Gore, Polegate, exhibited some fine specimens of Grapes Canon Hall, Muscat, Black Alicante, Gros Colman, and Muscat of Alexandria.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.

THE Chrysanthemum show of the above society, held in the Dome and Coin Exchange on the 1st and 2nd inst., was a decided success, the exhibits both for quantity and quality leaving nothing to be desired. Interest as usual centred round the large cut bloom classes, where many magnificent specimens of Japanese varieties were staged.

The leading class, that for thirty-six blooms in twenty-four varieties, brought out nine competitors with not a second-rate exhibit in the lot. Mr. A. Simmons, gardener to Sir Francis Osborne, Bart., The Grange, Framfield, for the second time won the first prize, consisting of a silver bowl, silver medal, certificate, and £3 in cash. Amongst other fine flowers were Duchess of Sutherland, F. S. Vallis, Bessie Godfrey, Miss O. Miller, Kimberley, Mme. P. Esdaelli, W. R. Church, and Geo. Lawrence. Mr. R. Draycott, gardener to Colonel Dudley Sampson, Ludfield, was a very close second, with deeper blooms; Mr. J. Pitts was third.

Mr. A. Simmons also carried off the first prize for twenty-five Japanese flowers, arranged in five vases, with their own foliage.

A feature of the show were six enormous blooms of F. S. Vallis, which were placed first in a class for six blooms, one variety, and were shown by Mr. J. Pelling, gardener to the Rev. E. C. Mackenzie Stuart, Framfield.

Mr. G. Hart, gardener to H. Head, Esq., Buckingham, Shoreham, was first for twelve incurved, followed by Mr. W. Hill.

Groups were greatly in evidence, the largest class, that for a group 14 feet by 8 feet, bringing out several fine arrangements. Mr. G. Sims, gardener to E. A. Wallis, Esq., Sunning-side, Upper Lewes Road, Brighton, carried off first honours, followed by Mr. H. Head, The Drive Nursery, Hove. For a group 11 feet 6 inches by 6 feet 6 inches Mr. H. Skinner, gardener to J. Dunk, Esq., Brighton, was first.

Trained plants are usually good at Brighton, and this year Mr. Lambert, 17, Begnor Road, Chichester, had the best four dwarf specimens, showing large plants well covered with flowers of good size. Mr. G. Eastwood, gardener to Mrs. Gould, Downs Hotel, Hassocks, had the finest twelve pots of single Primulas, and Mr. George Chandler, Lea Hurst, Withdean, was first for twelve pots of Begonias in flower.

A class not often burdened with a numerous entry is that for a collection of Orchids arranged on a table with Ferns, &c. Mr. H. Garrett, gardener to R. G. Fletcher, Esq., Withdean, was first, and Mr. George Stratford, Dyke Road, Brighton, second.

Mr. J. Davis, gardener to Major E. H. Thurlow, Buckham Hill House, Uckfield, arranged the first prize lot of nine Japanese blooms and any foliage in one vase; Mr. A. Findlay, second.

Mrs. Ruxley, East Grinstead, scored for an arrangement of Chrysanthemums and foliage suitable for a dinner-table, the best table of Chrysanthemums, Ferns, &c., coming from Mr. George Miles, Dyke Road, Brighton.

In the amateur and gardeners' classes, Mr. W. E. Anderson, gardener to B. Parish, Esq., Melodia, Preston Park, took the lead for a group of Chrysanthemums, 11 feet 6 inches by 6 feet 6 inches, followed by Mr. A. J. Blake, and the Brighton Amateur Challenge Trophy, to be won three times, for blooms to be grown within three miles of the Pavilion, went to Mr. T. Wells, The Bugle Inn, Brighton, there being considerable dissatisfaction over the decision of the judges.

In the fruit classes the competition was severely keen, some fine specimens being on view.

No less than twenty-two exhibits were seen in the class for four dishes of dessert Apples, Mr. Charles Crane, gardener to Mrs. Alexander, Hinton, Maidstone, being first. He showed Barnack Beauty, Ribston Pippin, Cox's Orange Pippin, and Swedish Reinette; Mr. F. W. Thomas, Waincock, was second. Culinary Apples were scarcely less numerous. Mr. F. W. Thomas was a good first in the class for four dishes.

Amongst exhibits not for competition were the following: Messrs. Wells and Co., Redhill, a few large-flowered Japanese, chiefly new, the best being Mrs. J. E. Dunne, something after the type of Miss M. Ware, but deeper, more decided colour; Mr. W. Knox, a large reflexed yellow; and Mrs. H. Partridge.

From Messrs. J. Cheal and Sons, Crawley, came a large number of Apples and Pears in variety.

Messrs. W. Balchin and Sons, Brighton and Hove, had very beautiful floral designs, composed of cut Chrysanthemums, Orchids, &c.

Mr. L. R. Russell, Richmond, Surrey, ornamental trees and shrubs in pots, and Messrs. Tilley Bros., Brighton, bulbs.

PORTSMOUTH.

The eighteenth annual exhibition of the above society took place in the beautiful Town Hall, on the 2nd, 3rd, and 4th inst. The exhibits generally were said to have excelled all previous attempts in quality as well as entries.

OPEN CLASSES.

For a group of Chrysanthemums, Mr. J. Agate, Havant, was first, showing a good arrangement with first-rate blooms; second, Parks and Open Spaces Committee; third, Mr. E. W. Gill.

Twelve plants of Chrysanthemums, not less than twelve blooms to a plant, brought forth good competition. Mr. G. Lambert was the first prize winner with well grown plants.

Perhaps the greatest interest centred on the class for forty-eight blooms, to consist of twenty-four Japanese and twenty-four incurved. This brought seven entries. The coveted award was handsomely won by J. B. Hankey, Esq., Fetcham Park, Surrey (gardener, Mr. W. Higgs). Included in the Japanese were Duchess of Sutherland, F. S. Vallis, highly coloured, S. T. Wright, Mafeking Hero, and Mildred Ware amongst the many highly finished blooms. The incurved were excellent in colour, size, and form. F. W. Flight, Esq., Twyford, Winchester (gardener, Mr. Neville), second; W. G. Adams, Esq., third.

For twenty-four blooms Japanese, Mr. J. Love, East Cowes, gained the first prize with a good collection; Mr. J. Agate, second, Mr. Neville, third.

For twenty-four incurved, not less than eighteen varieties, F. W. Flight, Esq., was awarded the first prize; Charles Curtis, Globe d'Or, and Duchess of Fife were the best selected; Mr. J. Agate, second; and Mr. C. White, third.

Amateurs exhibits were very good and numerous, the few selected here being specially so.

For eighteen blooms Japanese, Mr. Love won with capital blooms, followed by Mr. C. White.

For twelve blooms, Mr. C. White was easily first.

In the amateurs' section no less than eighteen classes were provided, each being well filled.

For a miscellaneous group, arranged in a space of 50 square feet, Messrs. W. Turner and Co., nurserymen, were awarded first prize with a very nice arrangement. B. Burridge, Esq., second; Messrs. Brickwood and Co., third.

For twelve table plants, W. H. Myers, Esq., first; Mrs. Hulise, second; Messrs. Brickwood and Co., third. Primulas were well shown and in quantity. For twelve, Mr. G. Lambert was first.

Table decoration, open to ladies only: Mrs. L. Fay, Portsmouth, first with Chrysanthemum Source d'Or and foliage very lightly arranged; Mrs. W. Sturt, Emsworth, second, and Mrs. W. Stanley, Coulsell, third.

FRUIT AND VEGETABLES

were largely shown in the open classes. The principal prize winners were Mr. C. Johnson, W. H. Myers, Esq., M.P., Swanmore Park (gardener, Mr. G. Ellwood); Mrs. Hulise, Haslemere, Surrey; Mr. H. Lee, Mr. H. Adams, W. Wadding, Esq., Mr. W. J. Ower, Sir William Pink (gardener Mr. W. Cheates), and Mr. W. M. Clay.

For six varieties of vegetables (prizes offered by Messrs. Sutton and Sons), eight competitors staged, W. H. Myers, Esq., being first.

CROYDON AND DISTRICT HORTICULTURAL SOCIETY.

A CAPITAL attendance of members and friends assembled at this society's rooms, Sunflower Temperance Hotel, on the 1st inst. to listen to a lecture given by a popular lecturer. The subject was "Birds of Our Garden," and at the hands of Mr. P. F. Bunyard, a member of this society and a local ornithologist, it was well expounded, both from the beneficial and

deleterious aspects of these feathered friends and foes. He had provided exceedingly good lantern slides of his subject, so that with the kind assistance of Mr. J. H. Bullock, who operated with the lantern, the illustrations thrown on the screen were lifelike representations. Some of the views were unique, and showed the extreme patience and energy displayed in getting snapshots from life of these timid creatures. In some instances the photographer had been obliged to wait days before his object was accomplished.

BIRMINGHAM CHRYSANTHEMUM AND FRUIT SHOW.

On Tuesday, Wednesday, and Thursday last this exhibition was held in the Bingley Hall, and was larger than ever before. There was hardly any space left vacant in the huge building that could be conveniently occupied. We should like to suggest that the groups of plants, both competitive and non-competitive, might be arranged so as to produce a much more pleasing effect as a whole. The pots and sticks and bare plant stems that were exposed to the gaze of visitors sitting on the seats provided in the centre of the hall to listen to the music were anything but pleasing; in fact, they detracted considerably from the beauty of the display. Why could not the competitive group be arranged in circular fashion in the centre of the hall, round the pillars perhaps, and the beautiful trade displays arranged on the ground around them? Then much ugly staging would be dispensed with, and when viewed from the gallery as well as from the ground floor, the effect would be much more pleasing. Our flower shows are not to be compared with those on the Continent for decorative effect, yet from the point of view of the public, a beautiful exhibition generally is of as much importance as a beautiful flower or group individually.

PLANTS.

The first class was for a collection of British-grown fruit to be grown by the exhibitor, and to occupy a space not exceeding 40 feet. The first prize was won by Mr. H. Weeks, gardener to Lady Byron, Derby. His Apples were richly coloured, the Pears very fine, the Grapes good, and the arrangement very pleasing. The tinted leaf-sprays of Ampelopsis were used effectively in decoration. Second, Mr. J. Reid, gardener to the Earl of Carnarvon, Burton. The fruits were very good, though they lacked colour on the whole. Third, Mr. W. E. Hyde, Ledbury.

The best nine trained plants of large-flowering varieties were shown by E. Martineau, Esq., Elghaston (gardener, Mr. O. Brasier), and J. A. Kenrick, Esq. (gardener, Mr. A. Cryer), was second. There were no other exhibitors. Mr. Brasier was first for six similar plants, and was the only exhibitor. The six trained plants of Japanese sorts were most attractive, being less stiffly trained. Mr. Brasier was again first, Lady A. Buller (yellow) being the finest. Mr. A. Cryer was second. Mr. Brasier was also first for three plants of Japanese sorts, for one Japanese, and for one large-flowering.

A group of Chrysanthemums, to be arranged in a space 20 feet wide, brought three competitors, the first prize being won by Mr. W. Thompson, gardener to J. Whitfield, Esq., Moseley. There were many good blooms and some indifferent ones. This group, which although the design was excellent, was somewhat stiffly arranged. Second, Mr. W. Sinford, Hall Green, with rather a heavy group; third, Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Elghaston.

CUT BLOOMS.

The class for eight vases of Japanese varieties, five blooms of each, made a handsome display. The first prize was won by Mr. E. J. Brooks, gardener to Lieutenant-Colonel Beech, Coventry, with some splendid blooms of much value for bold decoration. Henry Perkins, red, with yellow reverse to petals, was the finest; Bessie Godfrey, with yellow curling petals, was also very fine. Mr. C. Crooks, gardener to the Dowager Lady Hindlip, was a good second, such sorts as Mrs. G. Miteham, F. S. Vallis, and Mme. Radelli being well represented. Mr. F. May, gardener to H. O. Lord, Esq., Charlton Kings, was third.

For six vases, each containing five blooms, distinct, Mr. E. J. Brooks, Coventry, was first with handsome flowers; second, Mr. Crooks, F. S. Vallis being excellent; third, Mr. F. May, Charlton Kings.

For one vase each of four distinct sorts of Japanese, five blooms of each, Mr. Crooks was first, Florence Penford and F. S. Vallis being his best; second, the Leamington Nurserymen, Limited; third, Mr. Martin, Erdington.

For two vases, each containing five blooms of one variety only, the first prize was won by Mr. C. Crooks, Hadsor, Droitwich, with Mme. Paolo Radelli.

Mr. F. May, Charlton Kings, was first for one vase of a crimson Japanese Chrysanthemum, showing the variety Lord Hopton. The Leamington Nurserymen, Limited, had the best vase of white Japanese in Mrs. J. C. Neville, and Mr. Crooks, Hadsor, the best vase of yellow with F. S. Vallis.

The best eighteen blooms of incurved Chrysanthemums were shown by Mr. Goodacre, Elvaston Castle Gardens, Derby. The bright yellow C. H. Curtis was the best; second, Mr. W. J. Bastin, gardener to Sir A. Henderson, Birt, M.P., Raringdon, Berks; third, Mr. W. Manning, Dudley.

Mr. Brooks, gardener to Lieutenant-Colonel Beech, Coventry, was first for eighteen blooms of Japanese; these, with curling florets such as Duchess of Sutherland, Guy Hamilton, and Mme. P. Radelli were finely shown; second, Mr. J. N. Bush, gardener to F. J. Myers, Esq., Banbury; third, Mr. C. Crooks, Hadsor.

The best twelve incurved blooms were from Mr. Goodacre, Elvaston, Derby. C. H. Curtis, Giles, and A. Hills were the best. Mr. W. J. Bastin was a good second, and Mr. F. May was third.

For twelve blooms of Japanese Mr. W. Igzuden of the Flower and Fruit Company, Frome, was first, Guy Hamilton (white) and J. Kepton (yellow) being the most attractive blooms; second, the Leamington Nursery Company; third, Mr. F. May.

Mr. T. W. Piggett, Moseley, showed the best twelve blooms grown within four miles of Birmingham. Mr. Piggett also

had the best twenty blooms grown under similar restrictions. Mr. E. J. Byrne, Gravely Hill, was first for twelve blooms in the class open to those who have not taken a first prize before. In a local class for twelve blooms Mr. W. Manning, Dudley, was first out of several competitors.

The dinner-tables decorated with Chrysanthemums made a very pretty display. They extended the length of the hall, and were, with one exception, decorated with bronze and yellow flowers. The first prize was won by C. A. Palmer, Esq., Hadsorworth (gardener, Mr. C. Thomas); second, Miss Woolman, Tysley; third, the Leamington Nurserymen, Limited.

Mr. C. Kelland, gardener to A. H. Griffiths, Esq., Edgbaston, was first for a small group of plants.

Mr. A. Jeffs, gardener to E. Ansell, Esq., Bromsgrove, won first prize for twelve blooms of Japanese sorts on long stems.

FRUIT.

Mr. Goodacre, Elvaston Castle Gardens, Derby, was first for six bunches of Grapes, three varieties, with Muscat of Alexandria, Gros Maroc, and Alicante. Mr. J. Jones, Malvern, was second. He showed the variety Lady Hutt well.

Mr. T. Bannerman, gardener to Lord Bagot, Rugeley, had the best three bunches of black Grapes, and Mr. Goodacre the best three white bunches.

Mr. H. Folkes was first for two bunches of white Grapes, showing Golden Queen. The first prize for two bunches of black Grapes (local) was won by Mrs. Martin, Edgbaston, and in a similar class for white Grapes Mrs. Martin was also first.

For six dishes of culinary Apples Mr. W. Rose, gardener to E. W. Cradick, Esq., Ross, was first with handsome richly-coloured fruits; second, Mr. Crooks, Hadsor, Droitwich.

Mr. Charles Ross, Welford Park, Newbury, had the best six dishes of dessert varieties, all of his own raising; second, Mr. H. Wright, gardener to W. Waldron, Esq., Kingswinford.

The best eight dishes of Pears were shown by Mr. S. Postings, gardener to W. Williams, Esq., Wolverhampton; and Mr. Crooks, Hadsor, was first for four dishes.

VEGETABLES.

Mr. H. Folkes, gardener to the Right Hon. T. F. Halsey, M.P., was first for a collection of vegetables. Prizes offered by Messrs. Webb and Sons, Wordsley.

The first prize for a collection of vegetables (prizes offered by Messrs. Sutton and Sons) was won by Mr. E. Beckett, Aldenham House Gardens, Elstree.

Messrs. W. H. Simpson and Sons also offered prizes for vegetables.

Mr. Robert Sydenham, Tenby Street, Birmingham, offered numerous prizes for vegetables and a silver challenge bowl to the winner of the greatest number; it must be won three times to become the property of the exhibitor. Mr. H. Folkes, gardener to the Right Hon. T. F. Halsey, M.P., Hemel Hempstead, won the bowl with 32 points. Next on the list was Mr. T. Jones, Raddon, with 31 points. Mrs. W. A. Marrian (gardener, Mr. T. Griffiths) won the local cup with 28 points. The maximum number of points was 60.

TRADE EXHIBITS.

Mr. T. H. White, Worcester, exhibited hardy fruit and a collection of hardy shrubs; the Leamington Nurserymen, Limited, showed hardy shrubs; Richard Smith and Co., Worcester, sent shrubs; W. B. Child, Acock's Green a group of shrubs and flowering plants; John Waterer and Sons, Limited, Epsom, shrubs, e.g., conifers, Hollies, and Skimmias; Hewitt and Co., Solihull, shrubs in variety; the Vineries, Limited, Acock's Green, made a delightful display with hardy free-flowering Chrysanthemums; Baker's, Wolverhampton, exhibited a wonderful lot of Potatoes; T. C. Rivers, Edgbaston, sent trees and shrubs; Johnston and Son, Sutton Coldfield, showed single Chrysanthemums; W. B. Rowe and Co., Worcester, exhibited a grand lot of hardy fruit; Pewtre Brothers, Tillington, Hereford, and Mr. John Bisham, Bissley, also showed hardy fruit well; Gibbons, Altrincham, showed some beautiful single Chrysanthemums; floral decorations were shown by Messrs. Hewitt and Co., Birmingham; Perkins and Sons, Coventry, and Gunn and Sons, Olton; Mr. William Sydenham, Banworth, made a splendid display of border Chrysanthemums in some beautiful sorts; hardy fruit was shown by Messrs. Peed and Son, West Newbold, S.E., and by Messrs. R. Smith and Co., Worcester; Webb and Sons, Stourbridge, made a fine display with Potatoes and Begonias; Thompson and Co., Birmingham, sent Chrysanthemums and vegetables.

The King's Acre Nurseries, Hereford, showed hardy fruit extensively and well; Mr. Ambrose, Cheshunt, sent his new black Grape, as well as Carnations, Roses, Lilies, &c., tastefully displayed; Messrs. Wells and Co., Redhill, exhibited some very pretty Chrysanthemums; vegetables were shown by Messrs. Yates and Son, Birmingham; and Chrysanthemums by Mr. W. B. Child, Acock's Green. Mr. Robert Sydenham showed table decorations; and hardy fruit was shown from the Worcestershire County Council's Experimental Garden at Droitwich.

An exhibit of bottled fruits from the Lady Warwick College, Studey Royal, attracted much attention; Mr. W. Godfrey, Exmouth, Devon, had a splendid display of blooms of Japanese varieties, including many novelties, and hardy plants were sent from Bick Brothers, Olton.

The group set up by Mr. Deacon, gardener to the Right Hon. Joseph Chamberlain, M.P., was bright with Chrysanthemums, Begonias, Pelargoniums, Lilies, and stove plants in variety. Acalypha sanderiana was very handsome.

GARDENING APPOINTMENT.

MR. JAMES BETHEL, who has been gardener to Mrs. Walker, Westwood, Newport-on-Tay, for a number of years, is leaving to enter upon an appointment as foreman in the nurseries of Messrs. Storrie and Storrie, Dundee and Glencairn. Mr. Bethel has done splendid service as secretary of the Dundee Horticultural Association, and he has been a frequent prize taker at the leading local shows.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 5, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Names of plants.—T. W. Matthews.—*Boussingaultia baselloides*, a native of South America, from whence it was introduced in 1835. It is now fairly well known over a considerable portion of the globe. It belongs to the same natural order as the spinach.

Names of fruits.—F. E. S.—1, *Mere de Meaoge*; 2, *Emper Alexander*; 3, *Washington*; 4, *Damejew's Seedling*; 5, *Blenheim Orange*; 6, *King of the Pippins*; 7, *Alfriston*; 8, *Saundersham*; 9, *Cox's Orange*.

Begonia leaves diseased. (A. S. COLLINS).—We were rather puzzled by the *Begonia* leaves sent, and have shown them to several successful cultivators of this class of plants, nearly all of whom concur in the opinion that the discoloration of the leaves is caused by a very minute kind of yellow thrips, that do a considerable amount of damage before their presence is suspected. An examination of the young unfolding leaves may detect some of these pests, which are almost microscopic in character. The XL All Yapper is an effective cure for these, and nearly all other insect troubles, and that, too, without any damage to flower or foliage. One grower mentioned that he had observed much the same results from an excessive use of stimulants.

Clivia leaves diseased. (HOLT EN).—As far as can be judged by your letter there is nothing in the treatment accorded your *Clivia*s to account for the leaves being so severely attacked by rust as those sent. You say nothing about the condition of the roots—a most important item—and we are inclined to think that a good deal of the trouble lies there. Have you used any stimulating manure? If so, it may have acted injuriously on the roots. Our reason for making this suggestion is that two or three years ago we were consulted with regard to a collection of *Clivia*s whose condition left very much to be desired, the leaves of many being badly rusted. Enquiries elicited the fact that when reported a certain stimulating manure was mixed with the soil, and this acted so injuriously to the roots that on turning them out of the pots it was found that none of them had taken kindly to the compost, and the roots were altogether in a bad state. By our advice they were immediately after flowering shaken clear of the old soil, the decaying roots cut off, and the plants then repotted in just such a mixture as you describe. As most of them lost a good many roots they were put into smaller sized pots than before. After this the plants were kept rather closer and warmer than they were previously, and especial care taken not to overwater. The result of this was pots full of good healthy roots, and, though the amount of flower the next season was not great, the young leaves were quite free from rust, and they have gone on improving ever since, being again potted into the large pots from which they were removed.

Laurels as undergrowth. (HAZELDEANE).—All the Laurels may be used to form undergrowth beneath trees of large size, but they should be kept low by annual pruning. Where the groups of trees are large, the wide breadths of Laurel are very effective. Specially attractive are the groups of Birch springing out of masses of dark-leaved Laurel. But when Laurels are planted beneath large old trees, the ground should be well broken up, even if a few of the roots of the trees have to be sacrificed, and some old leaf-mould or charred rubbish worked in round the roots to give the plants a start. We think the round-leaved Laurel better adapted for planting beneath trees than the common variety. It is dwarfier and closer in growth, the leaves are smaller, and the plants will not require so much cutting back. Once get a plantation of Laurels established, and the plants can be kept in good condition for many years by layering a few of the young shoots annually. The shoots layered need not be touched or cut in any way. All that is required is to bend the shoot to the ground and throw two or three spadefuls of earth upon the branches where they touch the ground. Treated in this way, these wide breadths of Laurels are virtually indestructible, no matter what the weather may be if the annual pruning is not neglected.

Draining land for fruit growing. (HAMPSHIRE).—Every year adds to the acreage of land devoted to fruit culture. In very many instances the trees are not properly planted, as merely digging holes and thrusting in the roots can hardly be called good practice. One of the most important of what may be called preliminary operations is draining. Where any extent of land is laid down for fruit trees, if the soil is of an adhesive character, it would pay to put in good drains 3 feet deep and not more than 18 feet apart. After the drains are in, if the steam cultivator could go over the land two or three times so as to break it up thoroughly the work would be expeditiously and economically done. This breaking up would be of the greatest possible benefit, the water would pass away freely to the drains, the air would follow, and the whole mass of moved and aerated soil would soon be in splendid condition for the roots to work in.

Strawberries in pots. (R. E. JOHNSON).—The growth of these will soon be complete, but they are best left in the open as long as possible, so as to thoroughly mature the

crowns. The plants when standing on a hard, well-drained coal ash bed will take no harm. It is when they stand in places flooded with water and worms are allowed to get inside the pots that the mischief is caused. In wet seasons there is more difficulty with worms, but if the drainage is good and the pots stood as advised, there is little danger. We do not like the system of placing the plants along the sides of walks, as often they get more water than is good; the sides of walks being the lowest, the water is slower to run off and the plant is soddened. We would advise the use of strips of rough wood or racks when in such positions, as then feeding can be better attended to. Worms do less mischief and the walks are not disfigured. The resting or protection of these fruits when in large numbers is often a difficult matter. There is no better position for them than cold frames, plunging the pots in ashes or leaves, as in such places the lights can be removed in suitable weather and extra covering given if necessary.

Transplanting Oaks. (FOREST TREE).—Differences of opinion prevail respecting the advantages to be derived from Oaks raised direct from the Acorns in the woods as compared with those which are transplanted from the nursery; but there is every reason to believe that as good timber can be obtained by the one method as by the other. Where the young plants are inoculated in the nursery they generally flourish more vigorously after removal, and the process of heading down bark-bound and unhealthy-looking plants often in a few years gives them the lead of the more robust ones. Too much importance is attached to an undisturbed tap-root by those who forget that its main functions are lessened, or cease altogether, when the tree gets well established in the soil. Thus, when the top of an Oak assumes a rounded form, the tap-root ceases to descend, even though the lateral roots may still continue active.

The Elder as a nurse tree. (DOUGLAS COX).—We think you would find the Elder to be the most suitable for your purpose. In places where the strong west wind blows for several months in the year, and where even common Gorse looks as if it were rolled, the Elder will grow and thrive, and anybody about to start a plantation in such places would do well, as a preparatory step, to plant the ground in the interior thinly over with Elder bushes, but as thickly as possible along the margin, especially on the windward side. This skeleton plantation of Elder, filled in with timber trees, will have a massive and telling effect. Elder will also withstand sea breezes as well, and perhaps better, than any other shrub or tree. No other tree or shrub will grow in the shade or stand the drip of trees better than the Elder. In woods, the darkest and gloomiest spots may be made cheerful and lively by means of the Elder planted freely. As cover in woods and plantations, where little else would live, the Elder is valuable. Lastly, the Elder makes a good plant for filling up gaps in hedges, especially where they pass under trees, and for boundary fences, where nothing else will grow. It will preserve the continuity of a hedge right up to the trunks or stems of even Beech and Horse Chestnut. Moreover, a well-developed, full-grown Elder tree in full bloom when seen at a distance is a noble object.—R. B.

Black Currant tree diseased. (AN ENQUIRER).—The buds of your Black Currants are most decidedly attacked by the Black Currant mite (*Eriophyes ribis*). If you examine one of the buds which has been cut open under a microscope you will find that it contains any number of them. There is no positive remedy for this pest except pulling up and burning the infested bushes. Cutting off the infected shoots has been tried with but little success as a rule, but it has been known to be effective. I should certainly advise the more heroic method, unless the bushes had very few shoots affected.—G. S. S.

Ferns for baskets. (J. K. L.).—The culture of Ferns in suspended baskets might well be considerably extended. Either in the fernery or in the ordinary stove or greenhouse few objects are more attractive than hanging baskets filled with suitable Ferns. Many of the most beautiful species are only seen to advantage when grown in elevated positions where the long drooping fronds can mature their growth without coming in contact with other subjects or being smothered up with their own foliage. Either wire or wooden baskets may be used, but we prefer those made of wire, as they are more durable. The size of baskets should be regulated according to the requirements of the various Ferns, and also the accommodation that can be given them. Where space is limited the larger growing sorts should be avoided. In large conservatories, where plenty of space can be given, the larger baskets may be filled with a mixture of suitable sorts, but we prefer to use only one variety for each basket, for where several sorts are used the strong-growing ones soon cripple the weaker ones.

Protecting Celery. (W. H. KEELE).—Much unnecessary work is often entailed in the covering and uncovering of Celery. A little protection is beneficial, as, for instance, when a sharp and prolonged frost is imminent and where it is not covered with snow, but to cover up as some people do is not only unnecessary, but injurious, as it often causes decay to set in. Celery not forced on with heavy feeding and also well earthed up will not require covering up until very severe weather sets in. At this time a layer of straw or bracken should be laid along each side to facilitate the getting up, a little of the cleanest and longest being laid lightly along the top. Heavy coverings must be avoided. Protection from wet is far more needed, especially in those districts which are low-lying and in which rainfall is heavy. The best protection in these cases is to place a "cap" along boards together. These coverings must be laid along the tops, so that light will enter freely, this also allowing a

Autumn-flowering rock plants. (M. C. E.).—As all or most of the true alpine plants have their flowering season before the end of July, one cannot expect an autumn display of flowers in the rock garden if it is limited to these plants alone. Therefore, if flowers are wanted after this time, it can be managed by introducing some of the dwarf

and more compact growing herbaceous plants. These, however, should be planted so that they do not injure the smaller and choicer plants, which would have no chance if smothered by these coarser-growing subjects. Some of the autumn-flowering species of *Crocus* would prove useful, and might be planted between the looser-growing carpeting plants, such as mossy Saxifragas, Stonecrops, &c. The best of these are *Crocus speciosus*, *C. zonatus*, *C. hadriaticus*, *C. medius*, *C. longiflorus*, and *C. asturicus*. The *Colchicum* are also useful in the late autumn, providing a varied display of form and colour with their single and double purple, white, and other shades. The best are *C. autumnalis*, of which there are the above-mentioned varieties, *C. speciosum*, *C. giganteum*, and *C. byzantinum*. Among the dwarf herbaceous plants which may be mentioned as late flowering are: *Erigeron mucronatus*, *E. glaucus*, *Linum monogynum*, *Statice tatarica*, *S. sinensis*, *Pentstemon campanulatus*, *Isula Hookeri*, *Verbascum phoeniceum*, *Senecio pulcher*, *Stokesia carynea*, *Sedum Eversii*, *Liriope spicata*, *Polygonum vaccinifolium*, *P. affine*, *P. capitatum*, *Veronica Bidwillii*, and other kinds, *Hypericum polyphyllum*, *Spiraea lobata*, *Aster acris*, *Careopsis lanceolata*, *C. grandiflora*, *Lippia nodiflora*, and *Ceratostigma plumbaginoides*. *Cyclamen neapolitanum* is a very useful and pretty plant for the rock garden, as it takes up little room and remains in flower for a considerable time.

The dwarf Furze. (PLANTER).—The Furze has been frequently praised as a really useful and beautiful plant to grow in bold masses where other things are not likely to succeed, but the variety under notice is choicer still, for it bursts out into full flower when most things are putting on their autumn garb, and is bright and gay with blossom long after many shrubs are leafless. A slender, graceful bush rarely more than 3 feet high, somewhat drooping in habit and elegant in aspect, it might be planted in many places where the common Furze would be too large and coarse. Its flowers are much smaller than those of the ordinary kind, but profusely crowded on the shoots and of a bright yellow colour. Large groups of this Furze would give a welcome brightness to many spots about the garden grounds at this time of the year, and in coverts where ornamental effect is desired there is nothing to compare with it at the present time. All the *Furzes* transplant badly, and this no doubt is the reason of their scarcity in gardens, but they are easily established by sowing seed. A piece of ground just dug over to make a seed-bed and sown with seed of this Furze would want no more attention, as the seeds soon germinate, and the young plants manage to hold their own and get the better of native vegetation if they have a little start.

Jerusalem Artichokes. (CHESNIER).—These will now come in serviceable as a winter vegetable. They are best left in the ground and lifted as required. The newer white is a great advance on the old ragged form and equally hardy, but it is best to reserve as the lifting proceeds the most even tubers for seed, as with care in selection this form more resembles a Magnum Bonum Potato. This is a great gain, as there is much less waste in preparation and less trouble. Many condemn the old form on account of its rough, irregular shape, but even that can be much improved by careful selection. The Chinese Artichoke (*Stachys tuberifera*) is now ready for use. When crowded the tubers are small and less valuable. This variety makes a nice dish, and is often much valued as a change from the ordinary run of vegetables. The roots may be lifted at the end of the month and stored in earth or sand in the root store or left in the soil and covered with litter. The latter plan is best in mild winters, as the roots keep plump and are of much better flavour.

Striking Apple cuttings. (BEDS).—Directly the leaves fall select vigorous growing and healthy shoots of the current year's growth, but not too sappy. These make the best cuttings, and instead of cutting them from the tree in a haphazard manner, select those with which a small portion of old wood can be secured. By holding the shoot in one hand and the branch in the other and giving the former a sharp downward tug, the shoot is pulled out with the necessary appendage attached. Trim away from the base any jagged bark so that the "heel" will quickly callus over and remove the point of the cutting, leaving it not less than 10 inches or 1 foot long. A border with a western aspect is suitable for cuttings. The soil should be thoroughly broken up to allow the roots when formed to run freely. Dibble the cuttings in in rows 1 foot apart and 6 inches wide in the rows, dropping a small quantity of sand at the bottom of the hole, on which the cutting should rest. It is important that the cuttings be made quite firm and inserted not more than 4 inches deep.

TRADE NOTES.

A GOLD MEDAL FOR MESSRS. KELWAY AND SON, LANGPORT. The American Exhibition authorities have given a gold medal to Messrs. Kelway's beautiful exhibit at the St. Louis Exhibition.

A GOLD MEDAL FOR MR. JOHN FORBES, HAWICK, N.B. MR. FORBES'S beautiful exhibition of Antirrhinums, Pentstemons, Phloxes, East Lothian Stocks, &c., at the St. Louis Exhibition, U.S.A., was awarded a gold medal.

MR. AMOS PERRY, Winchmore Hill, London, has been awarded a silver medal at the St. Louis Exhibition for a collection of hardy plants in the "Old English Garden," all, with one or two exceptions, of Mr. Perry's own raising at Winchmore Hill.

CATALOGUES RECEIVED.

Trees, Shrubs, Roses, &c.—Messrs. Little and Ballantyne, Carlisle.

THE GARDEN

No. 1722.—VOL. LXVI.

NOVEMBER 19, 1904.

TREES AND SHRUBS WITH COLOURED FOLIAGE.

ALTHOUGH many of the so-called variegated leaved trees and shrubs are too poor ever to become popular, there is still a good number with foliage, of other colours than green, which collectively form a very important group, and which year by year become more and more popular with lovers of the outdoor garden. A few of them are very old favourites, and handsome specimens exist in many places. In plenty of gardens a fine Copper Beech may be seen conspicuous among surrounding greenery, while large patches of yellow turn out, on close inspection, to be due to the presence of the common golden Elder. Here and there the white variegated *Acer Negundo* adds colour to the surroundings, while the bronze leaves of *Prunus Pissardi* (of which, by the way, the correct name is *P. cerasifera* var. *atropurpurea*) are to be seen in almost every garden. These few things may be taken as worthy representatives of the group of which many striking examples are mentioned below.

The positions suitable for coloured leaved trees and shrubs are many and varied. The stronger-growing ones make noble groups or single specimens for important positions in garden or park, while those of dwarfer growth are eminently fitted for mixed shrubberies or for specimen beds on the outskirts of lawns and other places. In a large garden or park very fine effects can be obtained by massing coloured foliage trees, as, for instance, a group of Copper Beeches, silver *Acer Negundos*, variegated Sycamores, golden Catalpas, golden or variegated Elms, and other similar things. For a small or moderate-sized garden, however, the dwarfer things are probably more useful, and a mixed shrubbery has much to commend it, for by a judicious mixture of shrubs a very pleasing colour effect can be obtained. For specimen beds the plants require special selection, a few of the very best only being reserved for such places. In the list to be given those most suitable for the purpose will be mentioned.

Exception may be taken to some of these ornamental leaved shrubs—in fact, to the greater number—on the score that their flowers are of no garden value, but it must be remembered that, while the flowering period of most shrubs at the most extends over a few weeks, the period of beauty of these coloured leaved shrubs extends from the time the young leaves

appear in early spring until they fall in late autumn. Anyone who intends planting a group or shrubbery of these coloured leaved shrubs next season would do well, if not thoroughly acquainted with the plants, to pay a visit to some garden or nursery where they are grown during the summer, so as to become conversant with the material to be used, or, through not knowing the plants, one or another colour may be emphasised too much.

(To be continued.)

BRITISH GARDENERS' ASSOCIATION IN IRELAND.

At a meeting of the Irish Gardeners' Association, held on October 22 in its rooms, Grafton Street, Dublin, Mr. F. W. Moore, Curator of the Glasnevin Botanic Gardens, in the chair, Mr. F. W. Burbidge, M.A., Curator of Trinity College Botanic Gardens, in the course of his lecture on "Gardens and Gardeners," said, concerning ourselves as gardeners, you cannot organise a show of gardeners, but was it impossible to "grade" and lift gardeners as a class or body to a higher plane? Was it impossible to give the gardener a higher social status than he got from average society? All the learned professions seemed to have a stone wall round them. One reason was, of course, that professional men were all college men and educated at the university, and they got social status before they entered into their profession at all. It was impossible for most gardeners to get an education of the kind. But there was a beginning. There were colleges in connexion with the universities now starting, at which gardeners were being trained, such as at Reading, Durham, Edinburgh, and other places, and the chances were that the gardener would rise in the social line in that way. The head gardener's social position was legally that of a domestic servant. Mr. Burbidge thought that was a grievance. He might be, of course, a very superior domestic servant, but no more. Another thing was that at the present time any man might call himself a gardener, no matter what his education might, or, worse still, might not have been. Now, he asked, was it wise, was it desirable, was it right that gardeners, as a class, should rest content to be safe-guarded by a broken wall and an open door. Should they, as gardeners, suffer the bad effects of competition, of free trade, which was not fair trade, and was not some sort of co-operation and protection desirable? Nothing in the shape of an aggressive, domineering trade union would ever suit gardeners. It was possible to found an association that would secure the interests of the worker and also the interests of the employer. The experiment of founding such an association in England had already been taken up under the name of the British Gardeners' Association. The lecturer then dealt

in detail with the objects of this association, which, briefly put, were to compile a register of gardeners and gardens, and to regulate wages and working hours, &c. It was proposed to establish a branch of the association in every large town wherever there were sufficient gardeners to form one. This was, as far as Mr. Burbidge could remember, the first real attempt to organise gardeners of all classes under one flag, and if it proved a success, as he firmly believed it would, there was no doubt that it would not only elevate the social status of gardeners, and lead to their material advancement and protection, but also safeguard the interests of employers. He asked the officials of the association to consider the claims of the newly-formed organisation.

We are informed that an evening has since been appointed by the association for consideration of the question.

THE NATIONAL POTATO SOCIETY.

MR. A. DEAN says it is absurd to ask that Potatoes should be tested for flavour at a show. It is infinitely more absurd that an important food product should be judged simply by eye. What happens now is that variety after variety receives high awards for its size, shape, and colour on the exhibition table, and for its reported health and yield in cultivation, while, apparently, nothing is stated or even asked about its quality when cooked. I read my horticultural papers as carefully as most men, and did not succeed in discovering the word "flavour" in any report of the National Potato Society's show. I have never heard or read a single word as to the eatableness of Eldorado. It was announced the other day that the latest invention in Potatoes, The Pearl, changed hands at £1,000 per ton, but no one can tell me whether it is good to eat for man or beast, or either. There may be difficulties in cooking Potatoes at a show—I do not know that they are insurmountable—but there must be some way out of the ridiculous practice of judging food by looking at it. For instance, awards might be made provisionally, and subject to confirmation after a cooking test by a sub-committee. Mr. Dean seems to me to be on much firmer ground when he practically acknowledges that flavour pertains to the weaker races of Potato, and has dropped out of the coarser but more robust modern strains. If it is a fact that high flavour necessarily implies disease and extermination, then, of course, we must be content with these inferior, starchy monsters, though it will still remain true that they are inferior. But I should much like to have evidence that "any infusion of the yellow-flesh Ashleaf" necessitates disease. I may be wrong, but my impression is that the Ashleaf has been singularly overlooked by recent hybridists, and that practically no attempt has been made to infuse its fine

qualities into later and stronger varieties. I put down the insipidity of the modern white-fleshed Potato principally to the American blood, which it will invariably be found to contain, if pedigrees are traced. That most objectionable trick of quickly boiling soft outside and remaining hard in the middle is also due to the same source. It was very noticeable in Early Rose, Beauty of Hebron, &c., when they were first imported, as compared with English Potatoes.

I am afraid that "E. L. B.'s" argument that Up-to-Date, &c., must be good because they satisfy the cook, does not impress me. My whole argument has been that, unfortunately, the current taste is very low in the matter of vegetables and fruit. Let a Potato be big enough and starchy enough and the average cook is quite content. "E. L. B." might as well argue that a big, coarse, insipid Grape such as Gros Colmar must be of fine quality because the consumption is so enormous.

G. H. ENGLEHEART.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

PEAR CONFERENCE.

We have received from Mr. E. Carlyon, Belvedere House, Fontley, Fareham, Hants, fruits of the Conference Pear, which, it may be remembered, was raised by Messrs. Rivers and Son, Sawbridgeworth, Herts, in the year 1892. Our correspondent writes: "It takes its name from the Pear conference held at Chiswick at that time. It has received a first-class certificate from the Royal Horticultural Society. It grows and bears equally well on the free, Pear, or Quince stock. It has a good constitution, and is a most profitable variety for market. The unripe fruit is most excellent when stewed, and this is a very good way to utilise those fruits that fall or are damaged. The tree was planted in my garden at Fontley four years ago, against a wall with a south aspect. It was then three years old, and is trained to wire projecting 3 inches from the wall. The garden is situated in a clay pit. The border was well trenched, also well drained with brickbats. The clay was burned and the roots of the tree were spread out on the border, and a covering of 4 inches of the border soil laid over the roots, bringing it to a raised mound. This year the tree has borne over forty Pears like the specimen enclosed; in fact, the tree has borne a good crop each year. I consider it a reliable and profitable Pear to grow. Last year was a very bad fruit season, yet Conference bore a splendid crop. The roots were well watered during July, August, and September."

[The flavour is excellent. It is a handsome and shapely fruit, reminding one somewhat of Beurré Bosc.—ED.]

KERR'S CIGARETTE POTATO.

Mr. J. H. Ridgwell sends from The Gardens, near Histon, Cambs, a few tubers of this variety grown with Packard's Special Potato Manure. We have seldom seen finer or cleaner tubers, and the flavour is excellent. The following note is of great interest, and should be read by practical gardeners

and others who wish to achieve the best results from the land: "The tubers were planted the last week in June, and on land on which Brussels Sprouts had stood for two seasons (being saved for seed). No other manure was put on but 4 cwt. to the acre of this preparation. Messrs. Packard of Ipswich have evidently prepared an excellent Potato food, which quickly results in a grand crop of tubers of good quality. All growers of Potatoes should try this manure for themselves."

FLOWERS FROM THE ISLE OF WIGHT.

Mrs. Gwytherne-Williams sends from Belvedere, St. Lawrence, Isle of Wight, many interesting flowers, with the following note: "I am tempted to send you a small bouquet from my garden. The list is as follows:

<i>Tulbaghia violacea</i>	<i>Cassia corymbosa</i> (a mass of flower now)
<i>Swainsonia galegaefolia</i>	<i>Diplacus glutinosus</i>
<i>alba</i>	<i>Gowkera triphylla</i>
<i>Salvia angustifolia</i>	<i>Lagunaria Patersoni</i>
<i>Cyclamen persicum</i>	<i>Sutherlandia frutescens</i>
<i>Bouvardia triphylla</i>	<i>Manettia bicolor</i> , and a <i>Cypripedium</i> .
<i>Alfred Neuner</i>	
<i>Romneya Coulteri</i>	

All except the last have been out for years, but the *Sutherlandia* is not to be trusted to endure every winter unprotected, and the *Cypripedium* was put out only last spring."

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

November 23.—Annual Dinner of the National Chrysanthemum Society, Mr. C. E. Shea in the chair.

November 24.—Dramatic Performance, Cripple-gate Theatre, S.15, in aid of the Gardeners' Royal Benevolent Institution.

November 29.—Royal Horticultural Society at 1 p.m. Exhibition of Colonial-grown Fruit.

December 8.—Annual Meeting and Dinner of National Rose Society; National Amateur Gardeners' Association, Annual Dinner.

The Royal Horticultural Society.

Twenty-three new Fellows were elected at the general meeting held on Tuesday last, including Lord Armstrong, Lady Alexander, Mrs. Disraeli, and J. Lea Smith, Esq. The Peshurst Gardening Association was also associated to the society. The next exhibition and meeting of this society will take place on Tuesday, the 29th inst., subsequent to which the society will hold the first exhibition of colonial-grown fruit and of British, colonial, and foreign jams and preserved fruits, which promises to show what the colonies can produce for the home market, and will at the same time afford a comparative exhibition of the varying products of home, colonial, and foreign origin, which come under the description of jams and preserved fruit.

Horticultural Club.—A delightful lecture was given by Professor Boulger at the meeting of the Horticultural Club on Tuesday evening last on "Gilbert White and the Selborne Society." A report will be given next week.

National Rose Society.—At a meeting of the committee of this society, on Tuesday last, touching reference was made to the death of the Rev. A. Foster-Melliar. No less than eighty-three members have joined during the present month, thanks to the circulars in the nurserymen's catalogues setting forth the objects of the society. The metropolitan show next year will probably take place in the gardens of the Royal Botanic Society, Regent's Park, the Benchers of the Inner Temple having declined to allow the use of the gardens on the Embankment, owing to the disturbance to their members. A donation of twenty-five guineas was made to the New Horticultural Hall Fund, and it was decided to hold an autumn show next year.

National Amateur Gardeners' Association.—The fourteenth annual dinner will take place in the Crown Salon of the Holborn Restaurant, on Thursday, December 8, at 6.30 punctually. The chair will be taken by the President, Mr. T. W. Sanders, F.L.S. It is

earnestly hoped that every member will endeavour to be present, together with their friends. The tickets are 5s. each, and may be obtained from Mr. Richard Cordwell (hon. sec.), 35, Medusa Road, Catford, London.

"The Story of the Plants."—On the evening of the 8th inst. Professor R. Stewart Macdonald, Edinburgh, gave another of the lectures of his course on the above subject in the Blythe Hall, Newport-on-Tay. There was a large attendance, and Professor Macdonald's lecture was followed with the closest attention. The processes of pollination were lucidly explained, and interesting accounts given of the various methods adopted by Nature to provide for the fertilisation of flowers. The parts of the plants and their uses were also fully explained.

The planting season.—The young fruit grower is often puzzled about the selection of hardy fruit trees for planting. This refers more to Apples and Pears than any other, though such fruits as Plums, Peaches, Nectarines, and Cherries also are fairly numerous. With regard to planting I have very few remarks to make, but I would point out how necessary it is for future growers to think seriously before selecting their trees. There is no gain whatever in mere variety; indeed, in a private garden, unless it is for exhibition, it is a great loss, as by having so many sorts it often happens that there are not enough fruits of the variety most liked. The selections in THE GARDEN, page 314, should therefore be most useful and valuable to those who have not grown these fruits, but I would add it is of far greater advantage to grow say ten trees of one good variety than ten all different. To make my meaning clear I would much rather plant one hundred trees in ten varieties from the list given. In a few years the grower will then have a valuable asset, whereas if so many varieties are planted they may be interesting but not profitable. It may be urged that by having a large number some fruit, while others do not. I can safely say some of our most striking Apples at shows are very shy bearers, and some are of poor quality also.—GROWER.

Potatoes to eat.—I am extremely pleased that Mr. Engleheart has taken up the cudgels on behalf of the humble Potato, which, although of a naturally retiring disposition, has of late cut rather a dash. In this part of the country, where Potatoes are largely grown, only a moderate number of growers have become infected with the new disease, which has been diagnosed as "Potatoitis." I am acquainted with several growers who invested money in the much-boomed Northern Star. They grew an enormous crop, and now I suppose the long-suffering British public will be called in to consume it. With us, as with the majority of growers here, the variety Sir John Llewelyn is uneatable. At the present moment I am seriously thinking of forming a society for the protection of the public against horticultural "fakes," and shall be pleased to hear from any reader of THE GARDEN who is willing to co-operate. "E. L. B." has amused me. He seems to imagine that because Up-to-Date is popular its quality is beyond reproach. It is the old story of false ideals over again. As long as the grower has an enormous crop, and the produce which is put before the public is pleasant to the eye, the question of flavour is immaterial. What a dark day it will be for the market man when the palate of the public becomes so discriminating as to refuse Worcester Pearmain Apples and Beurré Clairgeau Pears! Perhaps "E. L. B." will explain to me why these fruits are (like Up-to-Date Potato) "always in demand."—ARTHUR R. GOODWIN, *The Elms, Kidderminster.*

Mr. M. J. Sutton.—The Corporation of the County Borough of Reading have taken a new departure in choosing as Chief Magistrate for the coming year a gentleman who has never hitherto been connected with the active work of the municipality; but that this epoch-making selection of Mr. Martin John Sutton, of Henley Park, Oxon, the head of the great Reading seed firm, gave as great satisfaction to the members of the Council as it has done to the burgesses at large was fully demonstrated when their choice of a new Mayor was formally ratified with the usual picturesque ceremony.—*Reading Mercury.*

School children and bulb growing.

With the view of encouraging a taste for flowers among the children attending the schools at St. Cyrus, N.B., the chairman of the School Board, Captain F. G. Forsyth Grant of Ecclesgreig, has again given over 3,000 Hyacinths, Narcissi, Tulips, and Crocuses to the children for cultivation during the winter. This is the second time Captain Grant has given bulbs, and the experience of last year showed that good results had followed his generous action. He is also going into the question of establishing garden schools.

"The Picturesque in Parks and Gardens."

This was the subject of a valuable lecture to the members of the Edinburgh society on the evening of the 2nd inst. The lecture, which was by Mr. James Craig, was illustrated by lantern slides, showing admirable examples of picturesque spots in parks and gardens in various parts. There was a crowded attendance.

Chrysanthemum Mrs. Chas. Davis.

Those who saw this variety on the stand of Mr. Norman Davis, at the recent National Chrysanthemum Society's Crystal Palace Show could not fail to be impressed with its rich beauty. It is an English-raised seedling, and is the result of a cross between two popular exhibition varieties, viz., Duchess of Sutherland and J. R. Upton. The blooms have all the grace and elegance of the first-named flower, and also possess more substance than that variety. The petals are very long and broad, drooping and curling most pleasingly. The colour is very striking, being a deep rich shade of orange-yellow aptly describing the tones represented. There is no other flower of Japanese origin so rich and beautiful. The floral committee of the National Chrysanthemum Society have asked to see the variety again.—D. B. C.

Silver variegated Elms.—Both the broad and narrow-leaved varieties are very effective in the form of well-developed specimens. They are slow of growth, and for that reason the ground should be well prepared for them. If small trees are to start away freely, and the owner wishes to reap the full benefit of his outlay in the shortest possible time, he must deeply stir and well manure the ground before planting.—J. C., *Byfleet*.

Chrysanthemums at Ballathie, Blairgowrie.

On Thursday, the 3rd inst., through the kindness of Colonel Richardson, Ballathie, the public had an opportunity of visiting the gardens there, and of enjoying the magnificent display of Chrysanthemums and other flowers of the season. Visitors from a considerable distance entered the gardens, and greatly enjoyed the display. The Chrysanthemums are remarkably good this season, and Mr. Davis, Colonel Richardson's gardener, was much complimented on his success. Many of the blooms are superb.

Milnathort Horticultural Society.

At a dinner held in connexion with the Milnathort Horticultural Association on the evening of Friday, the 4th inst., a presentation was made to Mr. Mann, who has acted as hon. secretary for seventeen years, as a mark of recognition of his valued services to the society during that time. The presentation was made by Mr. Stark of Struan Park, and Mr. Mann suitably acknowledged the gift, which consisted of a handsome gold Albert with appendages, suitably inscribed.

Memorial to the late Dean Hole.

The Mayor of Rochester (Mr. F. F. Smith) writes: "At a recent meeting held at the Guildhall, Rochester, it was decided that there should be in the city some permanent memorial of the late dean, and amongst those who expressed their approval and sympathy with the movement were the Bishop of Rochester, the Bishop of Southwark, the Lord-Lieutenant of Kent (Earl Stanhope), the Earl of Darnley, General Sir R. Hart, Admiral Craigie, C. Tuff, Esq., M.P., the Chapter of Rochester, the Mayors of Chatham and Gillingham, and several prominent residents of the district. It was also decided to form a large general committee, with an executive committee, and Mr. F. H. Day, of The Precinct, Rochester, was appointed hon. secretary, and Mr. W. J. Upton, of the London and County Bank, Rochester, hon. treasurer. Among the suggestions received for the

form of the memorial were (a) a recumbent figure of the late dean in the cathedral, (b) a new pulpit in the nave, (c) the restoration of some particular portion of the cathedral. It was thought best that the committee should make no decision until the views of the various subscribers were known, and it was seen what amount of money was likely to be available. It is desired to make the general committee as influential as possible, so that the movement may become generally known and receive support, and as there are many in different parts of the country who would be glad of the information of what is to be done, I should be glad if you would publish this letter in your paper. I shall be glad to receive communications from any persons who would be willing to contribute to the memorial, or who would desire further particulars sent to them." We may remark that the National Rose Society will have its own memorial of its late president.

Royal Scottish Arboricultural Society.

Information has been received that a silver medal has been awarded at the St. Louis International Exhibition to the Royal Scottish Arboricultural Society, for their interesting exhibit of photographs of American conifers grown in Scotland. There are twelve pictures, enlargements of photographs taken at Scone and Murthly by Mr. A. D. Richardson, landscape gardener and forestry expert, Edinburgh, the photographer of the Royal Scottish Arboricultural Society.

Chrysanthemum Miss Elsie Miller.

This is another of the beautiful acquisitions of the present season, and subsequent to the meeting of the floral committee of the National Chrysanthemum Society at the Crystal Palace was seen on Mr. H. J. Jones's stand. This new Japanese variety was raised by Mr. George Mileham of Leatherhead, who has given us so many fine sorts in recent years. In the present instance the plant is a seedling from the beautiful flowers of Miss Olive Miller, and the blooms exhibited on the occasion referred to represent an ideal type of the Japanese flower. The florets are very long and drooping, and they are also of medium width. It belongs to a type of Japanese bloom, of which there are too few representatives. The colour may be described as mauve-pink on a white ground. This variety was recently certificated by the National Chrysanthemum Society's floral committee.—D. B. C.

LILIES IN 1904.

(Continued from page 322.)

FOURTH in order of merit I must place *L. RUBELLUM*, which was as sweet and pretty as ever. One stem carried four flowers; one or two were unfortunately blank, but the rest had twos and singles, and the combined effect of their chaste pink blossoms against the dark background of Ferns and Lilac shoots was most pleasing. I saw this Lily spoken of rather contemptuously in *THE GARDEN* not long since as being "miffy" and short-lived, but I think the writer of such a character should give poor *rubellum* another trial. It seems quite happy here anyhow, in a poorish light soil full of stones and brickbats on a bank sloping to the north-east, which is overshadowed and robbed by a hungry, aggressive Lilac bush. I moved all my bulbs to this spot from a peaty *Rhododendron* bed in full sunshine, where they had previously merely existed for two years, in consequence of a letter in *THE GARDEN* from Mr. Barr describing the natural habitat of the bulbs he met with in Japan. It is a lovely Lily, and has lasted so long and done so well with me that I have promoted it to the "reliable" list, though, for all that, it is quite possible that pride will have a fall some day. After *rubellum* I suppose I must put

L. SZOVITSIANUM, though my old clump was very erratic and not as floriferous as usual, and

the bulbs elsewhere, planted from two to three years only, did not come to much. The six bulbs in the original group sent up their spikes most irregularly; one was in full flower when the last straggler had only just poked its nose through the ground, and there was consequently no great display at any one period. Still, there was a lot of bloom on the whole of a very satisfactory kind. A good sixth was

L. PARDALINUM, which flowered strongly and well, though the blooms lasted but a short time.

L. giganteum, seventh, was a success, three spikes flowering, and one of them being very fine.

L. Grayi did well, though not so well as last year, and the *Martagons* were quite satisfactory, especially *L. M. dalmaticum* and the variety *Catanii*. The *elegans* section were very handsome, too, and *croceum* was, as usual, admirable.

Then, a long way behind the leaders, "walking in with the crowd," as the racing phrase has it, were all my other poor *Lilies*, headed by *Parryi* and whipped in by *speciosum* and *sulphureum*. Though healthy-looking and quite free from the suspicious brown blotches on the stems and shrivelled leaves of last year, *Parryi* was rather feeble and diminutive. I do not think there were more than fifty flowers on the whole lot of the old bulbs, though a few of the seedlings of 1899 had a flower or two, both those grown in pans in a cold frame and those sown out of doors in a peaty corner. I have now just planted the former in the so-called "bog," where the old ones are. The seed I saved this summer was small, and though I did sow some in a pan I do not believe it will ever germinate.

L. SPECIOSUM seems to die out gradually with me, almost as surely as *longiflorum*. *Melpomene*, which was very fine last year and the year before, did nothing at all this autumn, while *Kraetzeri* and *rubrum* were very weak.

Either I have yet to discover the proper site and soil for this brilliant species or I must reluctantly give it up, as I have *longiflorum*, except for greenhouse treatment. It would be a great boon to Lily growers if one of their number who has really succeeded in establishing the *speciosum* section would kindly give the rest of us the benefit of his or her experience in the pages of *THE GARDEN*.

I have already mentioned *sulphureum*, and can only add that one of my two bulbs never came up at all, though it bore a single flower on a 7-foot stem last year, while the other produced a short stem about 3 feet high, thickly dotted with bulbs, but flowerless. Nevertheless, though I prefer to pin my faith on the bulbs, I do not despair of better luck with both bulbs another year, for in the cultivation of *Lilies* out of doors one soon gets accustomed to the caprices and vagaries of these coy divinities, some of whom seem to find it a pleasant and desirable change to "sleep the clock round" and mislead a year's labour in the upper world now and then.

L. Brownii was unsatisfactory, some of them refusing to show themselves at all, and those that did come up carrying a poor display of bloom.

L. excelsum, too, was nothing like as good as it has been, and my old-established *tigrinum*s were also poor. *Auratum*s in their second year were fairly good, and as they flowered most irregularly they made a useful show for a long time. My original bulbs, planted five and six years ago, are apparently done for. I have no suitable place for them, and must reluctantly abandon all hope of ever establishing them here, though my friend Mr. Herbert Green of Tovil, in this neighbourhood, had a fine display

from quite old bulbs in his Rhododendron beds this year.

This is about all of any interest I have to say about my "senior" Lilies. Of the "juniors," or those planted last autumn, some came up and some did not. There were certainly more labels than Lily stems, though I took no end of trouble in making a comfortable peaty bed in a sheltered spot for them, and expected a grand show.

A few were, however, quite worth working for, notably some new (to me) forms of *speciosum*, one of which, *monstrum*, was truly splendid.

Pomponium verum did well also (my old bulbs refused to flower), and so did *Humboldtii magnificum*, while I was very much pleased with the doings of *Wallacei*, a handsome apricot-coloured species which I had not tried before. Some new *canadense* flowered weakly, as did the old ones; but they are not really in a suitable place, and I cannot hope to do any good with them in the comparatively dry soil of even my dampest peat bed.

I had a nice bloom on a single *colchesterense* (odorum) in a Rhododendron bed, and am going to try one or two more bulbs. It is a handsome flower, and if the bulbs are planted on their sides, Japanese fashion, and covered with sharp sand in a well-drained soil, they should be a welcome addition to our *Enlirion* Lilies. *Superbum* gave a few flowers, but I am sadly in want of a swampy place for this Lily, as for *canadense* and others. Two bulbs of *tenuifolium*, though planted in a very special soil and warm corner, did no more than produce weak flowerless stems. I do not think it is much use attempting the cultivation of this delicate gem out of doors.

This completes, I think, my sad story of the Lilies for 1904, the result, in a great measure, of the cruel weather of 1903. I cannot, even in the words of the fairy tale, say of my poor bulbs, "and they lived happily ever after." Some of them, indeed, may do so, but I fear many

are permanently disabled or killed outright by the long periods of combined cold and damp they have been exposed to. Perhaps—and let us hope it may be so—we shall have a real good bloom in 1905, after the far more genial summer and autumn we have fortunately just been through. But if fate be still unkind let us not be disheartened. Let us remember that it is the damp rather than the cold that is against us, and let us take up and replant our old Lilies and put in new ones with yet more care, and more attention to the all-important subject of drainage. Stagnant moisture is responsible for far more failures and deaths among Lilies than a thermometer down to zero for weeks on end.

Yalding.

S. G. REID.

TREES AND SHRUBS.

THE BUSH OR TREE IVIES.

IT should be more widely recognised that in the finer varieties of the bush or tree ivies we have some of the most perfect of evergreens. There is a freshness, cheeriness, and distinctness about these shrubs that commend them to all who wish for a permanent feature in the garden of an evergreen character without a fear of introducing a dull and monotonous effect. The day will come, and, let us hope, soon, when diverse forms of Ivy will be much sought for, and why?—because of their manifold merits. We enjoy them as groups on the margin of the lawn, or in front of existing shrubberies; and it should be remembered that the green varieties are of the greatest use for planting under trees and in smoky towns. The gardener near a great city, such as Birmingham or London, is frequently perplexed as to the plants to select for their growth under such conditions. A

IVY AMURENSIS, SHOWING ITS VALUE AS A POT SHRUB.

hundred things that succeed elsewhere fail miserably; but not the Ivies, which even seem to enjoy their sooty environment. When September merges towards October the little balls of flowers appear, and every observer of the English hedgerow when all else is bare knows the sweet scent and colouring of the flowers of the Ivy, the one winter flower-picture to carry one's thoughts to the sunny time of spring. Bush Ivies may be planted now with perfect safety. The best selection comprises the following, all of which we have seen in large groups in Messrs. Fisher, Son, and Sibray's nursery at Handsworth, Sheffield, where these shrubs receive special attention. Of the green varieties none is daintier than *Amurensis*, which we have had occasion to describe before; *Canariensis*, *Rhomboidea obovata*, *Taurica*, and the yellow-berried variety with bright golden fruit which shines in the winter sunlight. The golden-leaved forms have their foliage splashed and blotched with yellow of various shades, and one of the best is *Gold Blotched*, a name that indicates the character of the leaf-colouring; *Palmata aurea*, and *Spectabilis aurea*.

GINKGO BILOBA.

THIS, the Maidenhair Tree, although introduced into this country so far back as 1740, does not seem to have found much favour with planters, a rather remarkable circumstance when we consider that it is an absolutely unique tree. Many exotics resemble in foliage either a fellow foreigner from some other country, and in some instances our own native trees, but this cannot be said of the Ginkgo. Also, it may be claimed in its favour that it is equally as beautiful. It may, I think, be safely asserted of this tree that it is admirably adapted for any site where a deciduous tree of average size is required. It may with advantage find a place in any

WALL OF THE BEAUTIFUL IVY AMURENSIS AT HAIFIELD (THE SEAT OF THE MARQUIS OF SALISBURY).

ornamental planting, and should be assigned a prominent position. Attention has been directed to the fact that it is a fine autumn tree, the decaying foliage very clear and pronounced in tint, and it may also be noted that the foliage is retained a considerable time, as many exotic trees, if a sharp early frost comes, are often completely stripped in twenty-four hours. B.

JAPANESE MAPLES.

I REMEMBER seeing a collection of the then newer forms of these Maples exhibited in London some forty years ago, and at that time there appeared to be a future for them, for they were very bright and interesting. But somehow they failed to hold their ground where introduced in the eastern counties and one or two other places where they were tried, though I think in the south they have been more satisfactory. The fault has been, where I have seen them planted outside (I am thinking now chiefly of the palmatum varieties), that they refused to grow freely and develop their lovely tinted foliage. In one sheltered spot where the soil had been specially prepared they have done better. But, even where they are not a success planted outside, they are worth growing for their decorative value under glass in the conservatory or in corridors in pots and tubs. There seems to be an increased demand now for Japanese plants, and these Maples are certainly worth attention for tub work on terraces or in the cool conservatory. Among the varieties worth notice are *Acer palmatum atropurpureum*, *dissectum palmatifidum*, *roseum variegatum*, *septemlobum*, and its varieties *elegans*, *laciniatum*, and *viride*. Of course, everyone who loves country life knows how beautiful the American and Norway Acers are in woodland scenery. E. HOBDAY.

COLOUR IN THE MIXED BORDER.—VI.

FOR section 7 we have again to employ blue flowers, and this can be dismissed with a few words. I should advise, as the next colour with which we have to deal is orange, that as far as possible the deeper and richer shades of blue at command be selected. These will assimilate better with the compound colour than the paler tints, and, again, I would use foliage plants. *Bocconia cordata* is very effective, as it will grow under favourable circumstances some 8 feet high, so it must be planted well back. This and the *Tiarella cordifolia* are both too little used; the latter is a lovely thing, and should be planted in the white section. Its leaves make a compact mat of tender green; it must be divided every two years, and it will thrive anywhere and everywhere. It would do equally well among the pink flowers, as its pretty creamy blossoms are tinged with pink.

For the orange section, No. 8, plant for a hedge the charming old-fashioned *Kerria japonica* or Jew's Mallow. It will supply an abundance of its pretty orange-tufted flowers for the spring months, providing it is never pruned. *Rudbeckia Newmanii* and Miss Mellish *Helianthus* are fine tall subjects for autumn flowering, as also are the *Kniphofias*, and there is actually an orange Hollyhock (Prince of Orange), which was one of Sutton's novelties last year. *Heliopsis scabra*, or, better still, Latham's *Heliopsis*, have fine rich orange blossoms. A good clump of Oriental Poppy, also called Prince of Orange, and in front of these, which are apt to grow very tall and somewhat coarse in rich soil, plant a handsome group of day Lilies, *Hemerocallis Dumortieri*, and *Lilium tigrinum* and *L. croceum* for different months of the summer. *Trollius Gibsonii* or *Fortunei*, *Orobis auran-*

tiacus, *Geum miniatum*, and *Gaillardias*, selected for their orange tints, will make quite a splendid show; but stake the *Gaillardias* early, so as to train them in the way they should go, and they will repay you. There are some lovely *Mariposa Lilies* of the right colour, but I do not think it is any use attempting to plant these exquisite and too little cultivated subjects in a mixed border, as they want special treatment as to soil and position to secure success in their cultivation. Wallflowers of the old double orange variety are difficult to get now, but the colour is marvellous. I should also select a few *Cannas*. *Chrysanthemums* for early flowering may be had, and in the foreground alpine and Iceland Poppies. I should have plenty of these

invaluable little perennials, for one must make the most of all our orange flowers. I think some of the Parrot Tulips might be admitted, and also the Orange Phoenix *Narcissus* and *Polyanthus Narcissus*. Of annuals there are not many, and here we certainly must not despise the homely Marigold culled by Simple Susan, for it now figures as Sutton's Orange King, and so reaches a height undreamt of by the ancient *Calendula officinalis* of the apothecary. Next in smartness come *Gazania splendens* and *rigens*, which, being half-hardy, must be grown in heat and planted out in May. These Sunflowers, I warn you, close when their monarch sets. For the rest we can have *Eschscholtzia crocea* (*Lasthenia glabrata*), a pretty annual from 8 inches to 1 foot high. Sow this in autumn for flowering with Wallflowers. Plant it thickly, but thin it out well. *Nemesia Strumosa Suttonii*, too, has an orange variety, and you must sow double Sunflowers for autumn flowering in the background. Of course, it would save a great deal of trouble, and doubtless be more effective

if the yellow and orange flowers were mixed in the sections 3 and 8, but I am not sure it would be as artistic. This, however, must be left to the taste and fancy of the reader. I have undertaken to carry out a certain colour scheme as well as I can, but after all it must be theoretical. The softer mauves and lilacs accommodate themselves equally well to orange or yellow. The mingling of ornamental Grasses and foliage plants will prevent any harshness of effect, and will increase the values of the yellow and orange, these colours being very assertive in half lights. The mauve or lilac flowers are a little confusing

if they are to be kept distinct from the purple tones. So many horticulturists persist in calling mauve flowers blue. There are two tints really, a bluish tint which is mauve, and a pinkish tint which is lilac; both tints are stolen from purple, and are therefore not true colours, but mauve is not blue, which is a primary colour. We can find a true mauve in a variety of named Phloxes and in an infinity of Michaelmas Daisies; but there are no blue Asters, any more than there is a blue Primrose, though there is an exceedingly disappointing little flower that figures as such. There are beautiful Hollyhocks, double and single, the Fig-leaved form (*Althæa ficifolia*) being exceedingly pretty, while the Sweet Peas Countess Radnor and Mrs. Walter Wright are

THE MAIDENHAIR TREE (GINKGO BILOBA) IN THE ROYAL GARDENS, FROGMORE.

not bad attempts at the colour, and there is the earliest flowerer of all, a Sweet Rocket. The next tallest perennial is called *Erigeron speciosus superbum*; this, too, is wrongly described as blue. To my thinking this is a charming plant; it is extremely floriferous, and blooms from early summer to late autumn, but this, too, wants careful tending and tying up. Then, of course, there are plenty of early-flowering *Chrysanthemums*. What a useful race of plants these are, just coming in when they are most wanted! I wonder what we did without them! The colours of the Canterbury Bells, too, are increasing in number,

and among last year's novelties was a mauve *Campanula calycanthema*. This colour is charmingly seen in Sweet Williams, Spanish Iris, Iris sibirica, and *Verbascum phoeniceum*, while for the foreground double and single Primroses and Violas, *Hepatica lilacina*, and *Aubrietias* are awaiting your orders, with pale *Anriculas* and *Anemones*, double and single. There is an old-fashioned Pink, without a name, that is of a most delicate shade of mauve. We have not done badly, and we still have annuals to complete our collection. China Asters, of which the pale lilac are the prettiest of all, and Mauve Beauty Stock, Linum, Scabious, and *Collinsia bicolor*: Poppies, too, in the French variety, and Phlox Drummondii, mauve, with a white eye, and Lobelia, though this perhaps is a little too purple. Foliage plants can be used with great advantage, and variegated sorts look well with the mauve tones. Soon, I believe, we shall have mauve Delphiniums. I had a sport in my borders quite a true mauve, but lost it again. We want a few taller plants to give strength to the centre of the plots, and then we should have a charming and delicate bit of colour in contrast to the vivid orange.

AUGUSTA DE LACY LACY.

SOME GOOD AUTUMN ROSES.

AS I write from a Midland garden, in mid-November, the wind blows half a gale, the sky is leaden all around, and the first real storm of autumn is evidently about to burst. Were it not for this untoward weather, I might, with quite a moderate stretch of imagination, describe the picture before me as summerlike. I am looking across a Rose garden that was planted some two years ago. The Roses are in beds, with grass paths between. Most of the plants bear at least one or two good flowers, on many one might count a dozen, and some are still in full blow of blossom and bud. The autumn has been an ideal one for Roses for the garden, whatever it may have been for exhibition blooms, and in this Midland garden from which I write Roses have been cut uninterruptedly from June till now, and still one could gather basketfuls of passable flowers. One cannot see a profusion of Roses in November without realising how much the gardener owes to the hybridist for his untiring efforts in the direction of improving old and raising new varieties, varieties that not only produce beautiful flowers, but produce them unceasingly as long as the plants are green. Easily best among the Roses of which I write is

Corallina.—The strong, reddish 3 feet high shoots bear quantities of coral-red flowers, and make a unique, delightful display. As with most other Roses that bloom in the autumn, the flowers have not the clear colouring that distinguishes this sort in the summer time, but the Rose enthusiast easily overlooks a small matter like that. In the case of

Liberty, however, one is liable to be disappointed for a similar reason. This Rose, whose colour in summer out of doors or in winter under glass, leaves nothing to be desired, assumes a purplish tint as autumn approaches that is not pleasing. It blooms freely enough late in the year, and if the buds are cut early and allowed to open in water the purplish tinge is not so apparent. A Rose that is comparatively little known is

Mrs. Stephen Treseeder, a white variety of that lovely Tea Rose Anna Olivier. It is a most valuable Rose, wonderfully free both in summer and autumn. The flowers are delicate, however, and are liable to be disfigured at this time of year by wind and rain.

G. Nabonnand has often been mentioned as a lovely Rose and a good one for flowering late in the season. Although the blooms have not quite the delicacy of rose and yellow colouring that distinguishes them earlier in the year, they are still most welcome.

Augustine Guinoisseau is not the last Rose of summer, but the last Rose of autumn. This variety yields flowers later than any other, it is always the last to say good-bye. Its loose, curled petals, always irregularly disposed at various angles, give to the flower an oddly though quaint appearance that makes it many friends. In the disposition of its petals, perhaps more than by any other character, this variety shows its affinity to La France. A white La France was the raiser's description of it.

Clara Watson gives some delightful buds at this time of year, and they are produced on such strong stems as to make a most useful decoration for a large vase. The pale flesh-coloured flowers are borne in profusion.

La Tosca is a Rose that one does not hear very much about. The pale silvery pink blooms that are now fairly plentiful on the ten or a dozen plants seem to show that it is as valuable an autumn Rose as it is a beautiful one.

Armosa, a Bourbon variety, is more often seen. Two beds of it are almost bristling with buds and flowers in this Midland garden, and for quantity of bloom it would be hard to excel. It needs to have a bed all to itself to show to advantage, then the deep pink flowers are seen at their best.

Zephyrin Drouhin, another Bourbon Rose, still has flowers, though these are not remarkable so much for their profusion as for their sweet fragrance, which is most marked. This Rose may be described as a low climber, and is perhaps best suited when planted against a short trellis.

General Schablikine, with its cherry-red buds and glaucous red-spined stems, makes a delightful plant for the garden in autumn, and should certainly be planted by those who like to have Roses out of doors as long as possible.

Grüß an Teplitz hardly needs any further recommendation, for it has so often been extolled in THE GARDEN. The crimson-red flowers on the strong erect shoots are produced almost as freely now as in summer. A valuable characteristic of this variety is that it is rarely, I might almost say never, attacked by mildew.

Laurette Messimy is also charming now. The flowers have lost a little of their delicate tints of course, but still they are very beautiful. It is curious to note the variation of colour in the summer and in the autumn flowers of the same Rose. Lady Roberts that is rich orange when typical is now quite white. Anna Olivier does the same thing, and so do other pale yellow Roses, while many of the reds lose some of their attractiveness in a purplish tinge.

Y. Z.

A GENERAL CALENDAR.

VIOLETS.

SINCE the plants were lifted and placed in frames the weather has been most favourable for them. The flowers have been abundant until now, and the plants quite free from spider, in spite of the dry weather during July and August. Many growers make a great mistake in coddling the plants after putting them into frames in October, keeping the lights over the plants and sprinkling them daily to enable them, as they say, to become established in their new quarters. Such treatment is quite unnecessary and injurious, and results in the leaves being drawn up. Plants properly grown and furnished with good balls of roots require no coddling or sprinkling, but simply a good soaking and full exposure day and night as long as the mild weather lasts, drawing the lights over at night, but tilting them up when slight early frosts occur.

Hepaticas.—These will not thrive in all places alike. Near large towns, with smoke and fog, they never look quite happy, often losing their leaves in winter, and with them much of their beauty. They also dislike compact and heavy soils, and should not be planted in north borders. With sufficient moisture most kinds thrive best in half shade, or, rather, screened by summer-leaving trees, and at other times exposed to light and air. When well planted Hepaticas may be left for many years, with only an occasional dressing of rotten

leaves or manure to correct their tendency to rise out of the ground. Where old tufts show signs of exhaustion these should now be taken up and carefully divided, and, if skilfully done, the plants soon recover from the check and grow with renewed vigour, fresh rich soil will always improve the flowers. Cut blooms are very useful for button-holes and small vases. A few plants should be wintered in frames and flowered under glass to provide early and perfect flowers for decoration.

Fig trees on walls.—Where it is necessary to lift or root-prune the work ought to be proceeded with without delay. The shoots should be freed from the walls and thoroughly cleaned before frost sets in. It is far better to do this work now than in spring, when the buds and young Figlets are swelling. In some places it is necessary to protect the growth during winter. Protection should be delayed as long as possible, in order that the shoots may get hardened previous to being covered. To those who contemplate reewing their trees I would not advise planting in the open till spring, for as plants may usually be procured in pots there would be less risk of their suffering should the winter be severe.

Forming Asparagus beds.—The work of preparation should now be begun. Naturally well-drained, free-working soils will produce good Asparagus without any special preparations for the crop, but cold clayey soils are not suited to Asparagus culture. Care must be taken in preparing the sites accordingly. Beds 4 feet wide and raised above the ordinary level answer well in the case of cold positions and heavy soils. A single pipe drain may be run down the centre of each bed, sinking this below the subsoil. Cover with coarse mortar rubbish, and on this wheel various accumulations of a nature to decay steadily and yet retain porosity, the upper layer to be formed of leaf-soil, fine mortar rubbish, sand, ashes from the garden fire, decaying stable manure, or any other material that will lighten and otherwise fit the soil for the production of Asparagus in large quantities, and for many years in succession.

Protecting Strawberries in pots.—There are several methods of protection, the old system of placing the plants one above the other is not good, for by this treatment the plants often get very dry. Strawberries for forcing should never be allowed to get dry, even when at rest. Cold frames are by far the best places in which to protect the plants. Here they may be plunged well over the rim of the pots in fine ashes, or, what answers equally well, dry leaves. These may be had in abundance at this season of the year. There need be no hurry to get them under glass as long as the weather remains open. Give a thorough watering before placing in their winter quarters, and care should be taken to see that the drainage is perfect.

Turnips.—These should be lifted before the frost is sharp enough to injure them, and for present use a few may be stored away in sheds or pits and covered with a little straw. For those to be kept through the winter I know of no better plan than to set them in rows, just as they are brought in from the beds, under a fence facing east, and nearly covering them with dry leaves. In this we always keep ours, and I invariably have good Turnips until the end of April.

Norwich.

T. B. FIELD.

RIVIERA NOTES.

A SUMMER of great heat and drought has left its mark on this coast, but the Palms, where sufficiently watered, have grown well, and the Australian and Cape shrubs and trees are all the better for the severe baking they have undergone. Roses have not yet made much growth, as the rain has been so long in coming, but in well cultivated ground they have not really suffered. It is the softer-growing things, such as Veronicas, some of the Buddleias, and Eupatoriums that are stunted or dwarfed by what they have had to endure. The heavy dews at

night are now refreshing vegetation, and preparing for the rain that doubtless will soon fall. Each year, on returning, the eye seeks for the combinations or contrasts of colour that have proved themselves in other seasons, and I note that nothing gives more lasting pleasure on the south walls than *Heliotrope* and white *Lantana*, with a good hedge before it of the deep red *Geranium* Paul Crampel, or *Denil de Miribel* if a taller one is required. The coral-pink *Fratelli Ferrairo* makes a good variation when reds are not needed. *Bignonia venusta* and the ever-flowering *Bougainvillea sanderiana* are a startling combination of orange and rosy mauve. *Tacsonia ignea* and white *Lamarque* Rose are matchless for pillars, but loveliest of all just now is the climbing annual *Mina lobata*, which wreathes pillars, posts, trees, and hedges with its forked sprays that shade from cream to crimson, and set off the sky blue *Ipomæas* or the blazing *Tropeolum lobbianum* that climbs so high. There is no flower that I know of that is of so pure a shade of light blue as this Indian annual *Ipomæa*, but it does not last as the *Ipomæa ficifolia* does, which persists into January in good seasons.

Everybody grows the well-known *Salvia splendens*, but how few know or grow the noble *Salvia frutescens*, which waves its large heads of scarlet bracts and flowers in the breeze at a height of 12 feet or more from the ground, when allowed to develop itself properly. By its side the fragrant *Buddleia asiatica* scents the air with its small white flowers in countless sprays, and rises to much the same height with a little help in the way of a strong stake. This should not be omitted from any winter garden, as its flowering is so prolonged and its fragrance so delightful.

Owing to the drought the growth of *Roses* and bulbs is much retarded, and probably December or January will give us better *Roses* than this year's November can offer. I see, however, one rather new pink climbing *Rose* that has already some good blooms, and promises to give a long succession in the coming months. *Mme. Ernest Calvat* is a strong growing *Rose*, said to be a seedling (or sport it may possibly be) of *Mme. Isaac Péreire*, a *Rose* of great value in England, but which is here quite put into the background by this bright pink flower of good size and great fragrance. The richly-coloured and very vigorous *Noëlla Nabonnand* is an excellent contrast and companion to this newer *Rose*, but it needs hard autumn pruning and abundant watering to make it start in such a season as this.

Big bushes of the orange-flowered *Leonotis Leonurus*, with many whorls of blossom on every shoot, are gorgeous when well set off by spreading masses of the old but ever welcome *Aquatum mexicanum*, which, when cut to the ground in August, makes now an enduring patch of soft and restful grey so welcome in this land of winter sunshine.

Rhus trifoliata is another very fragrant and elegant habited tree now in flower. It is so curiously like an *Acacia* in foliage and growth that, until its little greenish star-shaped flowers are fairly open, it is hard to believe it is not an Australian *Acacia*. As it flowers in November, it is not now so much grown as it deserves. Its elegance of growth, its freshness of slender green foliage, the fragrant flowery panicles that feather the length of the pendent shoots—all combine to make it attractive in the highest degree.

Perimenium discolor is bright with its little bouquets of golden *Daisies* on slender shoots, with narrow grey foliage. It is a plant that

has thoroughly enjoyed this dry hot season, so I fear it would not be very satisfactory under glass; but it is well worth a place here, as is also the old Cape shrub *Eriocephalus capensis*, which, with its neat heads of white *Daisy*-like flowers, is an excellent foil to *Perimenium discolor*. Both are in beauty in November and December, but *Eriocephalus* has another season of interest, as its flowers turn to white silky heads of fluff that remind one of *Cotton Grass* that is short in staple.

Nice.

EDWARD H. WOODALL.

THE FLOWER GARDEN.

CLEMATIS MONTANA.

THERE are many larger-flowered species and varieties, but there are few more beautiful than the Mountain Clematis. Not only is it very beautiful outside, but the shoots may be had of almost any length for decoration, and the individual blossoms are fine for any purpose. When placing on the turf or in borders robbed by tree roots the plants should be given a good start by taking the soil out to the depth of 2 feet, and filling this in with good loamy compost. Obtain plants, if possible, that have not become badly pot-bound, as these are the longest in starting. Plant firmly, and only loosely tie the branches at first, this giving the soil a chance to settle without straining the branches. The plants need a season or two to get thoroughly established, but after this flower profusely. H.

SOME NEW GAZANIAS.

THE *Gazanias*, especially those recently introduced, are so little known that it may not be out of place to give a short description of them. The distinctive characteristic of these beautiful South African plants is a conspicuous ring of spots, which adorns the base of the florets and forms a clearly-drawn and well-marked circle round the disc of the flower. Some species or hybrids are self-coloured, but more often the flowers are spotted. The spots are black, deep violet, or maroon in colour; frequently a white dot in the centre of each spot or the irregularity of the design heightens the

effect of the flower. In a monograph on these plants, recently published, the different species, hybrids, and variations which can be obtained in the horticultural market were described, and some of these have been used for the creation of the new hybrids whose description we now give. The following six have been chosen from more than 400 seedlings, and, in order that their qualities as flower-producers and for good shape might be well judged, they have been grown for two years. We can therefore recommend them with every confidence.

Diapré.—Vigorous, floriferous plant; large, well-shaped, full flower of a rich bright yellow; yellow disc, surrounded by black spots, with a white dot in the centre.

Bicolore.—A dwarf plant, rather inclined to spread, with lovely white flower, tinged with sulphur on opening, then becoming pure white; yellow disc, surrounded by a yellow border, then with a row of black spots; sometimes has a white eye.

Fleur d'Or.—Vigorous plant; large flower, rising well above the foliage, of a beautiful deep yellow, with the disc surrounded by a crown of black-brown spots.

Etoile.—A very beautiful variety; linear foliage; very large flower, star-shaped, white at the edges, sulphur-white towards the base, where there is a row of black spots; a very free and beautiful variety.

Papillon.—It might almost be said of this variety that it is a *Gazania splendens* with white flowers. The plant is dwarf and spreading; flowers beautiful and large, white in colour, adorned round the disc with black spots, dotted with white in the centre; an excellent plant for borders.

Rayon de Soleil.—Vigorous; flowers very elegant and well opened, of a beautiful pure bright yellow; very distinct, and remarkable for its colour. At the time I wrote the description of these flowers (August 15) the plants had been in blossom since May; this shows how free and continuous flowering they are. If to this it be added that the *Gazanias* accommodate themselves to almost any soil, and that they delight in full sun, in situations where few other plants could stand it, it will be acknowledged that these novelties, which are distinct from any hitherto existing, should be well received by those who love the beautiful among flowers. These varieties can now be obtained from M. E. Thiébaud.—JULES REDOLPH, in *Le Jardin*.

(From a photograph kindly sent by Mr. W. J. James, Woodside, Farnham Royal.)

NOTES ON HARDY PLANTS.

LOBELIA FULGENS.

FEW plants can be found to give a finer effect during late summer and autumn than *Lobelia fulgens*, especially in its robust garden form known as Queen Victoria. It is surprising that this variety is not more popular, for the maroon-coloured leaves and stems and vivid scarlet flowers never fail to attract attention. It may be a little tender as a herbaceous perennial, and probably is so in the colder parts of the country, but on the South Coast it gives no trouble, except that after the flower-stems have been removed the crowns, for precaution's sake, are covered with a slight mound of light soil, which is raked off again when all fear of frost is over in the spring. We find this better than taking up and sheltering the plants in a cold frame, a plan which is often recommended. If division or renewal of soil is advisable it is a simple matter to lift the crowns in April, replanting them at once in the fresh site or compost, when they will grow away without a check. Enquiries are often made for good plants suitable for permanent bedding. Here is one that may be suggested and recommended. Before the flower-stems begin to rise, the tufts of dark leaves cover the soil, and their sombre colouring is not amiss in the universal greenery of early summer. Later on the tall spikes, 3 feet to 4 feet high, are brilliant enough to satisfy the most ardent lover of colour. If a combination should be desired, bulbs of *Galtonia candicans* may be interspersed and will flower at the same time as the *Lobelia*, and such an effect has been much admired, but nothing looks better than the *Lobelia* massed by itself.

It is quite easy to work up a good stock as it grows freely from seed, plenty of which has been ripened this year. Most of our plants have been raised in this way, with scarcely any variation as to quality. Seedling plants, however, must not be expected to flower the first season. If possible, the seed should be sown as soon as ripe, and the seedlings, which are very minute, pricked off as soon as they can be handled into small pots, which can be set in saucers kept frequently replenished with water. *Lobelias* of this class are almost, though not quite, water plants, a fact learnt in gathering *L. cardinalis*, a nearly allied species to the Mexican *L. fulgens* under notice, amongst the water-washed stones on the bank of a Canadian river, as well as our native *L. urens*, a rare bog plant of Devon. The difference in the progress of seedlings treated liberally with regard to water and those grown in the ordinary way, and possibly kept rather dry, is remarkable. A thorough soaking now and then helped our clumps through the late dry season whenever they showed the least sign of drooping, an attention which was amply repaid.

A variety with deep rose-coloured flowers, which was seen in great beauty a year or two ago in Mr. Maurice Pritchard's nursery at Christchurch, is also very fine and well worth growing. K. L. D.

ANTHOLYZA PANICULATA MAJOR.

The broad, fluted leaves of the typical *Antholyza paniculata* are so handsome, and its scarlet and yellow flowers so striking, both in colour and in

form, in late autumn that it might well be planted with advantage in many gardens. It is also hardy enough in most parts of these islands if planted 6 inches deep, and, in cold and heavy soils, slightly protected with dry ashes or litter. Those who wish for a plant of distinct appearance may well grow it, keeping the crowns in dry sand until spring, or planting them in pots until March or April, when they may be planted out in their permanent situations.

It is not generally known that there is a larger flowered and larger leaved form, which is called *A. paniculata major*. It has, however, with me at least, the drawback of being rather too late in coming into flower, so that in seasons which are rather later than normal or very cold it fails to bloom. Next year I am going to try it in a more sunny position, and I anticipate that it will give more satisfaction there. It is a very handsome plant indeed, and those who wish a flower of such

PENTSTEMON BRIDGESII AT EXETER.

(From a photograph sent by Messrs. R. Veitch and Son.)

character may well grow it. The leaves resemble those of the *Gladiolus*, but are more ornamental. *Carsethorn, Scotland.* S. ARSOTT.

PENTSTEMON BRIDGESII.

This beautiful perennial comes from California, and will, no doubt, soon become popular. The accompanying illustration is from a photograph sent by Messrs. Robert Veitch and Son, Exeter, and represents one of the plants growing in their nurseries. As will be seen from the illustration the plant is of an elegant and light habit, and is most valuable for cutting. The plants at Exeter have flowered continuously since the end of July, and are now (the middle of September) still in

bloom. *Pentstemon Bridgesii* grows 2½ feet to 3 feet in height and flowers abundantly, a single plant often producing over thirty large, elongated panicles, each bearing hundreds of bright scarlet flowers of tubular appearance about an inch in length, with a cleft upper and a three-lobed lower lip. A closer inspection reveals a yellow mark inside the tubular corolla, from which protrude one sterile and four fertile stamens, bearing cream-coloured anthers. The green five-lobed calyx is small and, like the thin wiry pedicels, covered by very minute hairs. The main stems are glabrous, and are much longer in the lower part of the panicle. The leaves are opposite lanceolate, sessile, with a glabrous surface and margin entire, slightly undulating. They vary in length, being 5 inches to 6 inches long near the ground, but diminishing to the length of 1 inch or 2 inches towards the top. As the flowers are produced in great abundance *Pentstemon Bridgesii* will form a most desirable acquisition. It has proved perfectly hardy, and its culture is of the easiest. At Exeter it is growing luxuriantly in ordinary loam.

F. W. MEYER.

ROSE GARDEN.

HINTS FOR THE PRESENT SEASON.

THE following useful and seasonable information is taken from the excellent pamphlet "Hints on Planting Roses," issued by the National

Rose Society:

TREATMENT OF THE PLANTS ON THEIR ARRIVAL FROM THE NURSERIES.

When a bundle of Roses is received from a nursery care should be taken in unpacking it, so that in separating the plants none of the shoots or roots be broken off or bruised—any that are found so injured should be cut off. A shallow trench should be dug for their reception in any convenient spot, and the roots at once placed in it at right angles to the line of the trench, keeping as far as possible the different varieties distinct, so that when wanted any plant may be found without disturbing the others. The roots, as well as the lower parts of the stems, should then be well covered with soil. It will be found a good plan to pour some water over the roots, and also to sprinkle some over the shoots, before filling in the trench. If, owing to delay in transit, or any other cause, the bark on the shoots presents a shrivelled appearance, a deeper and wider trench than that required for "heeling in" the Roses (as the process is called) should be opened, and the entire plants placed lengthways in the trench. They should receive

a good soaking of water, and be covered completely with soil. After being left for three days the shrivelled appearance will have disappeared, and they can then be planted.

PLANTS ARRIVING WHEN THE GROUND IS FROZEN.

Should the ground be frozen when the plants are delivered, so that "heeling them in" is impracticable, they are best left unpacked in their straw covering. The bundle should be placed in a cellar or other unheated place, from which frost is excluded, until a thaw sets in, when they must be at once unpacked and "heeled in."

HOW ROSES OUGHT TO BE PLANTED.

Whenever it is possible Roses should be given a bed to themselves in an open spot, away from trees,

and not planted among other flowers. A bed 3 feet wide will hold two rows of plants, and one 4 feet 6 inches wide three rows. The distance between the plants for dwarfs should be about 18 inches, and for standards about 2 feet 6 inches. The beds having been made ready, and the position of the Roses in them marked out, the next thing, and the most important of all, is to see that they are properly planted. Some of the plants should be carefully removed from the trench where they had been "heeled in" and brought to the side of the bed they are intended to occupy. A mat should always be thrown over them to keep their roots from drying by exposure to sun or wind. A hole should then be dug about 1 foot square, and of sufficient depth, in the case of dwarf (or "bush") Roses, to allow the junction of the stock and scion to be about an inch below the surface of the bed when the operation is completed. In the case of standards the hole should be 6 inches deep. A plant should then be taken from beneath the mat, sprinkled with water, and held with the left hand in the centre of the hole, while with the right the roots are spread out horizontally and evenly in it, taking care that the roots cross each other as little as possible. Some of the finest soil available should next be sprinkled over the roots so as just to cover them. Over this light covering place 3 inches more soil, which may then be trodden in and the hole filled up. Tread the soil firmly round the plant when this has been done. Firm planting is very necessary for the future well-being of Roses.

In the case of heavy soils, or where the ground remains for any length of time in too wet a condition for the planting of Roses to be satisfactorily carried out, it is an excellent plan to secure some light gritty soil, such as the clippings obtained

from the sides of roads when the grass edges are being cut. A spadeful of this material may then with advantage be placed both above and beneath the roots instead of the natural soil. Soil of this character may be firmly trodden without caking together, and the grit in it encourages the early formation of roots. When planting Roses singly on lawns or elsewhere the same method should be followed as when inserting them in beds. Where Roses are planted in the spring the shoots should be pruned before planting.

(To be continued.)

NOTABLE GARDENS.

THE GARDEN AT THE MANOR HOUSE, SUTTON-COURTENAY, BERKS.

AT this beautiful place the garden is divided up into three parts—the Long Garden, the Pleasaunce and Wilderness, and the River Garden. The Long Garden, with its high clipped Box hedges and enclosing stone walls, is devoted entirely to masses of Roses, herbaceous borders, Lavender and Rosemary hedges, pergolas of creepers, and carefully kept grass lawns. By proper and careful planting colour is assured throughout the summer.

Walking under an avenue of immense dark Yews, one emerges into the roseroy. A Yew

hedge surrounds the carefully mown grass, in which are formally planted standard Rose trees of various kinds. In the centre stands a fine white marble Venetian well-head and iron top. Walking through the roseroy one turns into the Pleasaunce, a delightful place in spring as well as in summer. In spring the carpets of Daffodils, Jonquils, Narcissi, and Crocuses are very lovely, as they grow out of the grass and are overhung by the old gnarled Apple trees. In summer, when the spring flowers are over, the flowering shrubs, Roses, Brooms, and Gorse, with the shady trees, make the Pleasaunce a pleasing place indeed. Leaving the Pleasaunce, one crosses the drive to reach the Wilderness, a more open spot, but surrounded by many fine timber trees. Returning through the house, one wends one's way down towards the river Thames, which is less than 200 yards distant. Before the river is reached a word must be said for the River Garden; here no garden beds exist, but everything is a profusion of green grass, damp-loving shrubs, and Roses, which surround an expansive lawn. Here you look down an alley of climbing Roses, which overhang the Water Lily walk; there, down a pleached Lime avenue; and, further on, you look out into the old lush meadows, with the river gleaming beyond. A winding path leads down to the boathouse and river. The Water Lily path, made a few years ago, turned out to be a complete success. A long red-brick path, bordered by grass, extends for 100 yards or so; in the brick path are sunk tanks of water, in

THE LONG GARDEN AT THE MANOR HOUSE, SUTTON-COURTENAY (THE RESIDENCE OF CAPTAIN H. LINDSAY).

which various-coloured miniature Water Lilies live, while overhead is a wooden pergola of climbing Roses, the effect being very pretty. In hot summer weather the effect of the River Garden is a cooling one, with its rank-growing shrubs and grass. At Sutton-Courtenay the river Thames is seen at its best and quietest—broad winding reaches, bordered by meadows and fringed with trees, Willows, Osiers, and Rushes.

CHRYSANTHEMUMS.

NEW CHRYSANTHEMUMS AT THE NATIONAL CHRYSANTHEMUM SHOW AT THE CRYSTAL PALACE.

A WELL-ATTENDED meeting of the floral committee was held at the Crystal Palace, on Wednesday, the 2nd inst., Mr. D. B. Crane in the chair. Owing to the great November show being held on the same date, novelties were numerous, and many certificates were voted to praiseworthy sorts. Those receiving recognition were as follows:

Mrs. A. H. Lee.—A really handsome Japanese reflexed bloom of great breadth. Petals very long and fairly broad, also of good substance, making a monster spreading bloom. Colour rich crimson, with golden reverse. First-class certificate awarded to Mr. N. Molyneux, The Gardens, Rookesbury Park, Wickham, Hants.

G. F. Evans.—An immense incurved flower, having broad petals, slightly pointed, building up a beautiful flower of globular form. Colour chrome-yellow. First-class certificate granted to Mr. W. J. Godfrey, Exmouth, Devon.

Emblème Poitevine.—A massive-looking incurved flower, with petals of medium width, making an exhibition bloom of deep build. Colour, a beautiful rich yellow. Petals slightly hirsute. First-class certificate also to Mr. Godfrey.

Buttercup.—This is an incurved bloom of the largest size and one of great promise. The flower is of wonderfully even form, having broad petals of splendid substance neatly incurved, and of deep build. Colour, buttercup-yellow, as the name implies. First-class certificate to Mr. Godfrey.

W. A. Hetherington.—A deeply built Japanese flower of beautiful form and solid and massive character. Petals long and fairly broad. Colour, rosy mauve with white centre. First-class certificate awarded to Mr. Godfrey.

Mrs. A. T. Miller.—This is a pure white seedling from the popular Japanese exhibition variety Miss Olive Miller, and with such parentage should be highly valued. Broad petals pleasingly incurving and curling, make a large flower of good substance. First-class certificate awarded to Mr. G. Mileham, The Gardens, Emlay, Leatherhead.

Miss Elsie Miller.—Another charming seedling from Miss Olive Miller, developing blooms of ideal Japanese form. This is a very large and refined flower, having very long petals of medium width, evenly reflexing and drooping, and great depth; colour, mauve-pink on white ground. First-class certificate also to Mr. Mileham.

Miss E. Holding.—This is a pretty silvery rose incurved bloom, with a much deeper shade of rose on the inside of the broad petals, of good form and good substance. First-class certificate to Mr. W. Seward, Hanwell.

Margaret Brown.—Another pleasing silvery rose incurved bloom, with broad petals of good shape. Distinctly promising. First-class certificate awarded to Mr. Seward.

Miss Tuckey Bird.—This is a large single-flowered sort of good form and pleasing character. Fairly broad petals of good length, and arranged in neat order round a well-formed yellow disc. Colour, creamy white. First-class certificate awarded to Mr. H. Redder, Manor House Gardens, West Wickham.

W. Gooding.—A beautiful exhibition Japanese bloom of deep build, having broad petals, prettily recurving. Colour, mauve-pink, with silvery reverse.

First-class certificate to Mr. T. Bullimore, The Gardens, Canon's Park, Edgware.

There were many promising sorts that were ignored, and others that the committee wished to see again. Of the latter the following is a brief description:

Mrs. A. Arno's.—A grand reflexed Japanese of even form, with broad petals. Colour, rich crimson, with bright golden-yellow reverse. A very large flower.

Mrs. Frank Penn.—A glorious rich yellow reflexed Japanese bloom, with erect, fairly broad petals when finished.

G. W. Matthew.—This is a pale, bronzy yellow incurved flower, with long petals of medium width. Promising.

Maurice Sargent.—Large, solidly-built pearly white flower, with rosy violet inside colouring to the broad petals of good substance. This is a promising incurved bloom of globular form.

Mrs. Chas. Davis.—Without a doubt the richest yellow Japanese flower in cultivation. It is the result of a cross between Duchess of Sutherland and J. R. Upton, and is a bloom of grand quality. Broad, curling petals of great length; colour rich orange-yellow.

Prospers.—A large-flowered single of good form, though with rather too many rows of petals. Its colour is its chief attraction, and this may be described as a shade of salmon terra-cotta.

THE KITCHEN GARDEN.

PROTECTING VEGETABLES AND SALADS.

MUCH has to be done in the kitchen garden at this time in the way of affording protection to winter vegetable crops. Many of these are only half hardy, and even the hardiest require the gardener's attention in some minor details if a regular supply of fresh vegetables is to be maintained throughout the winter and early spring. A denuded kitchen garden in the early part of the year is sure to result after a hard winter if protection is not given in due time, and especially is this the case after a mild autumn such as we are now passing through, because the various crops will be soft and sappy, therefore more susceptible to injury through having made rampant growth.

The expense of the necessary material is a small matter in most instances, and practically nothing in country gardens if the gardener is resourceful.

Bracken is frequently to be had for the cutting, and if cut now before it becomes quite brown it will last for a long time. Rough stable litter used when clean and fresh is suitable for many purposes. Branches of Yew or other evergreens answer for certain young growing crops, and other materials I have used are Reeds and Rushes cut from the sides of watercourses and the dry stalks of the Asparagus.

I will deal briefly with each of the vegetables and salads that most demand our attention.

CELERY.

This valuable salad plant is much damaged by frost, and as it is expected to last during the winter adequate protection should be afforded in time. One of the greatest safeguards is firmly to fix the soil that is banked round the stems to prevent the frost entering at the top. I advise that no covering be done until the plants have had some 5° or 6° of frost upon them, then shake loosely over them about 3 inches of dry litter, which should remain until the frost breaks, when it may be carefully drawn into the alleys for future use.

BROCCOLI.

The old plan of heeling these over with their heads facing north has much to recommend it, as it gives a check to growth, thus hardening and preparing them for severe weather. As with Celery, it is best to allow them to freeze a little, then shake some dry litter over their heads during the continuance of the frost.

CAULIFLOWERS.

Where a succession is maintained from early autumn until Christmas the later batches should now be heeled over as advised for Broccoli, with the exception that the heads should face the south. In gardens having abundance of house or pit room at disposal it is better entirely to lift the plants, taking care to retain a ball of soil if possible. They may be transplanted into any ordinary garden soil, and will continue to yield nice medium-sized heads for a long time.

COLEWORTS.

These rank among the most delicious of winter green crops, and, although nearly hardy, are better for being protected with a thin covering of dry litter. This is not a large order, as Coleworts are generally planted closely together.

CABBAGE.

The plants set out for spring cutting have made rampant growth this autumn, owing to the prevalence of mild weather, and to ensure their passing safely through the winter some soil should be drawn now to the stems for protection.

SPINACH.

This esculent is always appreciated, especially in early spring, when green vegetables are scarce. The young plants will now be strong and provided with abundant leafage. This should not be picked too closely at this time; but before severe frosts set in the lower leaves may be gathered for use and a little soil drawn to the stems. During severe spells of frost some Bracken or dry tree leaves should be worked among the plants with the hand and allowed to remain until danger of severe frosts is past.

GLOBE ARTICHOKE.

Although this is a summer vegetable, the plants require adequate protection from this time until the spring. Few vegetables are more tender than this. Bracken or other litter should be carefully worked among and about the crowns, thus forming a mound round each clump.

PARSLEY.

The scarcity of this herb in many gardens during winter may safely be attributed to lack of protection. Assuming that seed was sown in July, especially for providing strong plants for winter picking, a frame should now be placed over them and all fully-developed leaves cut off; this will promote the formation of new roots and top growth for winter use. Some gardeners sow or transplant into raised frames in July or August, and where convenience exists the system is a good one, as they are more under control. If a frame cannot be devoted to Parsley, some strong plants may be carefully lifted, taking care not to damage the fleshy tap-roots, and planted in boxes for placing in the greenhouse.

LETTUCE AND ENDIVE.

Those sown for autumn and winter use should be lifted when quite dry and planted in rough frames or pits. Failing these, a piece of ground not too rich, in a sheltered part of the garden, may be prepared for them, and they may be covered with old lights, or with dry litter or evergreen branches. These salad plants must be fully grown, or nearly so, at lifting time.

H. T. M.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

THE FLAME FLOWER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—To many of your readers "A. D.'s" note on page 271 will be strange reading, because it has become almost a matter of history that, though here and there are spots which are made to suit the Flame Flower, one must go to Scotland to find the congenial home and successful culture of this favourite Tropæolum. There is no doubt that it is a glorious flower when it will flourish, but many

have failed with it. Three years since I obtained tubers and planted them in prepared soil on a north border, where it could climb an erection of wire netting. I was the first year able to congratulate myself on the success of the venture, for it made nice growth, and gave a bright touch of colour to that part of the garden. The next year the growth was feeble, and this, instead of progressing, dwindled away. This season at about midsummer growth appeared again close to where the original plant grew, and has since gone up the wire some 2 feet. I am puzzled as to the source of this renewed growth after so many months of slumber. Though almost a weed in Scotland, there are few places where it is seen thriving in the milder counties of England. If Dean Hole despaired by reason of his want of success and made such facts known, there would naturally be many deterred from attempting its culture, but although advertisers have of late years brought this bright flower prominently before the gardening public, the memory of Dean Hole's failure would not be forgotten perhaps. It is a misfortune that such a lovely flower has such exacting growth. Were it possible to plant in sunny spots instead of shady ones, how much more effective floral pictures might be made!

Wills. W. S.

POTATO AND WHEAT CROPS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In Mr. Molyneux's estimate (page 295) of the returns for an acre of Wheat, he forgets to reckon the value of the straw. I agree with his figures otherwise. My estimate of £12 was in any case meant to represent a maximum, the utmost the Wheat grower could hope for. A. D. HALL.

Rothamsted Experimental Station, Harpenden.

POTATO THE FACTOR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I am pleased to see your correspondent "H. E. R." writing so favourably about the merits of the above Potato, and I can quite bear out all he says regarding it. I first grew this Potato several seasons ago, and was so pleased with it that I recommended it to others, all of whom share my opinion. It cannot be called a boomed variety, and its price is not prohibitive, but it is certainly one of the best main crop Potatoes on the market at the present time, and had it been sent forth with a flourish of trumpets like many others I have no doubt it would be much more valuable. In addition to being a heavy cropper and a splendid cooker, I have found The Factor to be an excellent disease resister, and even in 1903, when most varieties succumbed, this Potato with me grew quite free from the trouble. I would remind any who propose giving The Factor a trial that it is a strong grower and should be given plenty of room. I allow 3 feet between the rows, and find this is none too much if crowding is to be avoided.

G. H. H.

TWO GOOD SUMMER AND AUTUMN SHRUBS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The Wig Tree or Cloud Bush has seldom been better than during the past summer. When a bush of this some 30 yards in circumference, well flowered, is seen, it is a beautiful sight. I saw a tree of this size during the past season. The autumn effect produced by this shrub is to me really finer than when in flower, especially so if it happens to be *Rhus Cotinus atropurpurea*, or, better still, *R. cotinoides*. The latter is most attractive just now. It is the best for autumn effect. *R. C. atropurpurea* has a great deal of bronze and purple about it, and in certain positions is a most telling plant now; but it should be kept away from such shrubs as Laurels, Yews, and heavy shrubs of this kind, while the effect is improved by their presence in the case of *R. cotinoides*. There are few plants so suitable for an isolated specimen as either of these beautiful shrubs. Moreover, they are hardy and need very little attention, unless it be when there is a heavy fall of snow. They

are then liable to break, as the wood is somewhat brittle. There is always a certain amount of dead wood to be cut out each spring, for they lose some of their young growth each year, and unless this is removed the shrub looks untidy all the summer. There is a variety grown in this neighbourhood called *R. coccinea*, the flowers are said to be redder. This is also a fine autumn shrub, and should be planted with the others. One word about the method of propagating *R. cotinoides*. This is generally grafted or budded on *R. Cotinus*, and the result is that frequently the common stock gives a great deal of trouble, so much so in some instances that it has killed the scion outright in a few years. Could not this beautiful shrub be layered instead of worked on the common and more vigorous stock?

Cirencester.

T. A.

LONICERA HILDEBRANDTI.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I send you a photograph of my plant of *Lonicera Hildebrandti* to show the progress it has

LONICERA HILDEBRANDTI IN A TORQUAY GARDEN.

made in two years and ten months since it was planted out of a 4-inch pot. It has produced fifteen bunches of flowers this year. It will probably bloom on all the laterals next year, and will be very ornamental. The scattered trusses at the top opened first, one or two at a time, then those on older wood at the bottom.

Blythwood, Torquay.

P.

SHRUBBERIES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In a recent issue of THE GARDEN Mr. Hobday says that "every planter ought to make himself acquainted with the average height and dimensions that the trees will have when they reach full development." This is excellent advice, but your correspondent might go further and include all kinds of shrubs, and especially those that delight with their blossoms. The fact is planting is too frequently done in a haphazard fashion, the object being to furnish the ground quickly. Cheap coarse-growing things, such as Chestnuts, Laurels, &c., are associated with comparatively slow-growing, choice-flowering shrubs, which in time either die out or come into a condition that renders them useless from an ornamental

point of view. There is no reason why the shrubbery should not be as attractive and full of interest as the conservatory. Among those things used for the decoration of glass houses can we find anything finer than the Pearl Bush (*Exochorda*), *Berberis Darwini*, the *Weigelas*, *Philadelphus*, and other things too numerous to mention? *Hydrangea paniculata* is as fine as its relative *hortensis*, and does not need half as much care. Chinese and Ghent Azaleas are as beautiful and effective as their relatives which demand the shelter of a glass house, and there is nothing more pleasing than a well-developed bush of *Laurustinus* or a good plant of *Spiraea arifolia* when in full bloom. A few loads of peat or good loam would make all the difference in the welfare of some things which the natural soil is unsuitable for. It is not only the preparation of the rooting medium, but after-care that is needed. In a general way no systematic thinning or pruning is practised, the consequence being that the weaker-growing things are smothered or deprived of their decorative worth. We know what is likely to happen if such things as *Spiraea arifolia*, *Weigelas*, *Kalmia*

latifolia, and *Berberis stenophylla* are intimately associated and no restriction imposed on any of them. It will be a case of the survival of the fittest—the weaker members must go to the wall. The shrubbery can be made a delightful place, but only if some of the care lavished on tender and indoor things generally is bestowed on it.

J. CORNHILL.

MALMAISON CARNATIONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Having read the very interesting article on Malmaison Carnation culture, I would like to ask the writer if the article was intended for the amateur or professional gardener? In the first place, the writer says the plants are layered on August 21, and on September 27 severed from the old plants when nicely rooted. Then I find your correspondent waits until October 10 before the layers are potted up, and until February before they are transferred into flowering pots. Now, I would like to ask Mr. West what advantage he gains in delaying potting? In the first instance, after severing the layers from the old plants, when he might be taking advantage of the longer days in September in getting the plants well started before

winter. Having had considerable experience in market culture of Malmaisons, I find the usual practice is to layer in July, sever the layers, and pot them up about the third week in August into 3-inch pots, then about the third week in September they are ready for another shift into 6-inch pots. In this way the plants are well established before the winter. Why are the plants left until February before being potted into 6-inch pots? I find after flowering another small shift is given into 8-inch and 9-inch pots; then again in February the following year they receive their final potting into 10-inch and 12 inch pots. I would like to ask the writer what advantage is gained by a second shift? The usual practice amongst Carnation growers is to give them one shift after flowering into 8-inch and 9-inch pots, according to the strength of the plants, then when nicely rooted to start feeding. By this practice we get our plants in bloom in April and May, which are the two months that I find Malmaisons realise the best price. I should like to know the average number of blooms the two year old plants carry, measuring 6 inches and 7 inches across. W. G.

Sandbeck Gardens, Rotherham.

BENTHAMIA FRAGIFERA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Will seedling plants of this shrub give fruit, or must they be grafted? Ten years ago I raised some plants from seed received from Cornwall. They have grown luxuriantly, but have hitherto shown no sign of fruiting. So far the plants have not suffered from wintry weather, although they are growing in the open and without any protection. E. M.

THE CLIMATE OF BRITISH COLUMBIA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Your correspondent writing from Sweden in the issue of THE GARDEN for October 8 (page 247), seems to be under the impression, like a great many more people, that British Columbia has a very severe climate. It is a large province, and the climate is very variable. In the north and north-east the climatic conditions are very severe, but the south-western portion is mild, and the nearer one gets to the coast the milder is the climate. On the lower mainland and on Vancouver Island the climate resembles that of the south of England, only the summers are drier, with a lot of rain in winter—from 50 inches to 70 inches on the lower mainland, and here in Victoria about 35 inches usually falls. The maximum temperature ranges from 70° to 90°. The nights are always cool, too cool for Grapes, Peaches, Tomatoes, &c., that are grown outside. The thermometer seldom runs down to zero; last winter the coldest weather we had was on the last day of February and March 1, when 14° of frost were registered. That small amount did a great deal of harm; nearly all of my Peach buds were killed on the young budded stocks. At the present time the soil is so dry that it is impossible to dig up trees or plough land. We have had no rain to speak of for about five months. I was at Vancouver (seventy miles north from here) about a week ago, and they were digging trees with ease, the land being quite moist. They get some summer and early autumn rain there.

In my note on the Loganberry there was a typographical error; it should have been "tips," not "slips." The tips are buried a few inches in the soil in September and October, and every tip will make a strong plant (not separated as slips would be). Loganberries are doing well in the interior of British Columbia, where the thermometer falls below zero. G. A. KNIGHT.

Mount Tolmie Nursery, Victoria, B.C.

P.S.—We had fair crops of fruit of all kinds this season, and Apples in some places very heavy. Plums were worst; they were attacked by aphids, and I am sorry to say that rot or fungus has attacked them also. Large quantities decay on the trees, and even after they are picked.

GARDENING OF THE WEEK.

FLOWER GARDEN.

ANEMONES.

WHERE the soil is light and moderately dry these tubers may now be planted; but with a heavy soil and in cold localities it is wiser to defer the planting until the end of February or early March. The soil should be rich and deep. Allow plenty of room, at least 9 inches between the plants and a foot from row to row, planting the tubers about 4 inches deep.

There are many beautiful varieties to choose from. If cut flowers are the chief consideration, one would largely plant the giant French Poppy Anemones, which produce enormous flowers and have a great range of colour. The St. Bridg Anemones are also very showy and free flowering, and are chiefly double or semi-double. The ordinary single and double-flowered varieties can be obtained mixed or in distinct colours—scarlet or blue. These are more used for beds and planting in clumps. There are many named kinds, and several of the early-flowering species are well worth a place. The herbaceous Anemones may now be increased by division. The old *A. japonica* is still one of the best, as also is its variety *alba*, more commonly known as *Honorine Joubert*. The variety *Whirlwind*, illustrated in THE GARDEN on the 29th ult., is very beautiful and desirable, and *A. japonica rosea* freely produces flowers of a pleasing rose colour.

RANUNCULUS.

The remarks re planting under Anemones also apply to the *Ranunculus*, except that they require more moisture. During severe weather both plants should receive some protection.

LILY OF THE VALLEY.

If it is intended to lift the crowns and make new beds, this work may now be proceeded with. The details were given in "Gardening of the Week" for January 30 last.

BORDER CHRYSANTHEMUMS.

It is many years since the early Chrysanthemums were in such great beauty as they have been this autumn. Some surplus plants of the large-flowered kinds, which were planted at the foot of an old wall and in vacant spaces in the borders, are still in full bloom. These were not disbudded, and all the attention they received was an occasional watering during the summer and tying when necessary. Should the winter be mild they will probably furnish some sturdy cuttings. The varieties which have done best are *Lady Smith*, *Mrs. Geo. Mileham*, and *Viviani Morel* and all its sports. The October varieties proper are now over; the old flower stalks should be cleared away and the plants may be lightly mulched as a protection during the winter. It is a good plan to take a few cuttings of each desirable variety and insert them, fairly close together, in pots and place under a handlight in a cool frame, where they will quickly root. The selection of varieties is largely a matter of individual taste and requirements. There are many new varieties, but few are more useful than *Mme. C. Desgrange*, *George Wermig*, *Roi des Procees*, *Market Prince*, and *October Yellow*.

SEEDLING HERBACEOUS PLANTS.

Many hardy plants raised from seed in the spring are now fit for planting in their permanent quarters. The perennial *Caillardias* will flower well next June. In the rush of newer herbaceous plants these showy subjects seem to suffer undeserved neglect. They should be planted near the front of the border, and any surplus plants may be planted in the reserve garden to furnish cut flowers. The *Eastern Poppy* (*Papaver orientale*) and *P. bracteatum* should go a little further back. Once planted these are impatient of root disturbance. If cut just as the flower bud shows a tinge of colour between the sepals of the bursting calyx, they will travel long distances and open well in water.

Flowers so treated last longer than when cut fully expanded.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

FRUIT GARDEN.

WINTER CUCUMBERS.

THESE have made a healthier growth than usual, chiefly owing to the outside atmosphere being so favourable for providing ventilation. The plants have been supplying fruits freely and are still showing more, but do not overcrop them, especially where a good supply is expected from the same plants during December and January, when continuous firing is necessary. The plants should be encouraged by a light top-dressing of rich fibrous loam, some horse manure, with a sprinkling of bone-meal added as soon as the roots appear on the surface through the previous dressing, care being taken that the soil is well warmed through before using. Water must be carefully used at this season, and always at the same temperature as the house. The plants should also have occasional sprinklings of Thompson's Manure, and watered with weak liquid manure, care being taken, however, not to overfeed them, as a sturdy growth must be encouraged. Remove all male flowers and tendrils as soon as they appear, and stop the shoots first or second leaf beyond the fruit, according to space. Pay attention to regulating the growths, and allow plenty of space for the principal foliage to develop. A night temperature of 68°, more or less, according to the outside atmosphere, and 75° to 80° by day will be suitable, with a chink of ventilation on all favourable occasions. Later sown plants should be allowed to make a freer growth before pinching, and be cropped lightly. Very little syringing will be necessary, with the exception of damping the beds, paths, &c. A light dewing over of the plants occasionally on bright days early in the afternoon will do good, and help to keep down red spider.

POT STRAWBERRIES.

These will soon require to be placed in their winter quarters in pits or frames, where they can be protected from heavy rains and severe frosts. They should still have all the air possible by having the lights removed altogether, except when the above conditions prevail. Where pits or frames are not at disposal, they may be plunged up to the rims in ashes outside to protect the pots from breaking, and in very severe weather a light covering of Bracken may be thrown over them. I do not advise laying the pots on their sides, as I think they become too dry, and do not do so well afterwards. Where early fruit is required forcing must soon begin. A Strawberry house is the best place, as the plants must be near the glass, forced slowly, and the house free from draughts. An early Peach house just started, where the night temperature does not exceed 48°, is also a good place. The old-fashioned way of plunging the plants in leaves in a light airy pit, where the bottom-heat does not exceed 65°, always gives good results with ordinary care and attention. No syringing is necessary in this case, and very little water until the flower trusses appear, as the fermenting leaves will provide sufficient moisture.

WINTER TOMATOES.

These will now be carrying good crops of fruit, but owing to the absence of sun they require a much longer time to ripen. Maintain a warm, dry atmosphere, with a night temperature of 60° in mild weather, and a crack of ventilation on all favourable occasions. Fertilise the flowers daily, keep all side growths removed. Carefully water the plants, and top-dress them before they become exhausted with good fibrous loam and some horse manure, with an occasional sprinkling of some artificial manure.

FRUIT ROOM.

Examine and remove all decaying fruits, and spread out remaining varieties of Apples which are too crowded. The less ripe Pears are handled the better. Allow a free circulation of air to pass through the ventilators to carry off excessive moisture.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

BRUSSELS SPROUTS.

OWING to the exceptionally mild autumn these have made extra strong growth. The decaying lower leaves should be cleared to allow plenty of air about the plants. This vegetable is generally planted too thickly, the result being a great loss of leaves and poor quality. It will pay to pull out some of the plants if ample space has not been allowed. The earliest plantings are fit for use, but will improve greatly after a touch of frost. If the garden is an exposed one a good moulding up should be given to prevent damage by wind.

FORCING ASPARAGUS.

Roots that have been specially prepared for this purpose will now start readily provided the tops ripened off early; but if they have not ripened a supply of roots will have to be got from an earlier locality. They may either be grown in a warm pit or frame or in the Mushroom house; if in the latter a temperature of about 60° will do well. No great depth of soil is needed—6 inches is sufficient. Spread the roots on this, and cover to a depth of 5 inches with light soil. Give a sprinkling of tepid water to settle the soil. Keep the house or pit close till heads appear. Failing a heated pit or Mushroom house this vegetable may be successfully forced on hotbeds, although, this

or decaying leaves, and give plenty of air. Lift sufficient Rhubarb to meet all requirements, and cover with leaves till required for placing in heat.

Hopetoun House Gardens,
South Queensferry, N.B.

THOMAS HAY.

THE FRUIT GARDEN.

CORDON GOOSEBERRY TREES.

DURING the past few years the Gooseberry has received more attention from cultivators. The best flavoured kinds are now better known, though these are not the most showy fruits. Some time ago there was a splendid exhibit of Gooseberries in the new hall of the Royal Horticultural Society, nearly a hundred varieties being staged, and among them were the best dessert varieties. Where this fruit is not a success I would say try cordons; often a north or east wall can be made one of the most profitable in the garden when covered with these trees. The culture is quite simple after the trees have become established. It is necessary to spur back foreright shoots, extend the main growths, and thin out when required. This method of culture has other advantages over the ordinary bush trees, and especially, where birds are troublesome. Such

garden. I would refer to the value of the trees when grown in palmate form. This is very suitable for some sorts, especially those of drooping habit, and all do not do well as cordons. Some cordons have two branches, others four; for walls I prefer the latter, that is, two shoots on each side, or say five, one central one and two each side. This is commonly called gridiron training. Of course, where no expense is spared it is an easy matter to cover a wall with single cordons. Single cordons may also be made most useful if trained to stakes in lines. I do not admire this mode of training other than to form the trees at the start; still it is advantageous for small gardens. I do not advise standard Gooseberries; although ornamental, many kinds do not succeed when grown in this manner.

As to culture, there must be a good root-run to get the best results, deep digging, and ample food in the way of decayed manure. I advise early planting, from mid-October to late in November. The earlier the land is got ready the better. Mere surface-digging will not suffice, as the trees will be in the same spot many years, so that they need deep culture. For flavour the small-berried kinds are the best. At the same time, the large ones are more useful for cooking, as these may be gathered so much earlier. Telegraph and Philip the First (greens), Beauty and Bobby (reds), Freedom, King of Trumps, and Lancer (whites), and Keepsake and Leveller (yellows) are good large kinds. The new May Duke is a valuable early berry, and Whinham's Industry is a valuable red. For flavour Green Hedgehog, Green Gage, Crown Bob, Keen's Seedling, Warrington, Shiner, Golden Drop, Keepsake, Yellow Rough, or Sulphur and Golden Lion are the best. Among the new kinds recently sent out having splendid flavour are Golden Gem, Langley Beauty, and Langley Gage. When grown on walls these fine-flavoured fruits are delicious.

G. WYTHES.

THE NEW GRAPE MELTON CONSTABLE.

GRAPE MELTON CONSTABLE.

THIS new black Grape, of which we give an illustration, has been exhibited a good deal recently by Messrs. Ambrose and Son, Cheshunt, who hold the stock of it. It is the result of a cross between Gros Colmar and Lady Hastings, and was raised by Mr. Shingler, gardener to Lord Hastings, Melton Constable. It is of good flavour, and the berries are large and handsome. That it travels well and keeps well Mr. Ambrose has demonstrated at numerous exhibitions within the last month or two. This new Grape is a late variety, and is said not

to be at its best until Christmas or even after. Several medals and certificates have been awarded to this Grape. The three bunches shown in the accompanying illustration weighed 15lb.

BULLACE THE LANGLEY.

I SHOULD like to draw attention to the remarks of "A. D." in THE GARDEN of the 5th inst., page 302, in which he takes Messrs. Veitch to task for giving an inappropriate name to this fine fruit. The true facts are as follows: It was shown for the first time before the Royal Horticultural Society on Tuesday, October 7, 1902, and reported in the Society's Journal, 1903, Vol. XXVII., pt. 4, page ccix., as follows: "Messrs. James Veitch and Sons sent Damson The Langley, raised by crossing The Farleigh Damson with Black Orleans Plum, &c." The Royal Horticultural Society's fruit committee decided to test its cooking qualities at Chiswick before giving it an award, and at the following meeting, Mr. S. T. Wright having reported as to its cooking qualities, it received an award of merit under the name of Langley Bullace. This transaction is reported in the above-named Journal, page ccxv., as follows: "A.M. to Bullace 'Langley Bullace' (votes unanimous) from Messrs. J. Veitch, from Farleigh Prolific Damson x Orleans Plum,"

entails a great deal more labour. To have a lasting bed mix fresh stable litter and leaves in sufficient quantity to form a bed 4 feet in depth, and place a one or two-light frame on the top. Trample and beat the fermenting materials when building the bed, and leave it untouched for a few days until the heat seems to be steady at about 80°. Place a layer of soil over the bed, and plant as recommended for those grown in pits. The frame should remain close and covered with mats until growth begins. When lifting Asparagus roots for forcing the work should be carefully performed, the clumps should be lifted with as little injury to the roots as possible. A portion of a bed should be lifted, and not single roots all over the ground. The land may then be dug, manured, and prepared for replanting.

GENERAL FORCING.

Another supply of Sea Kale crowns should also be now got in. These will start more quickly than those put in three weeks ago. Continue the weekly sowings of Mustard and Cress in boxes. French Beans in bloom will require careful attention. Syringing should be discontinued until the fruits are set. Tie and train winter Tomatoes and Cucumbers as required, and give air on fine days. Inspect Lettuce in frames, remove all decayed

trees are easily netted, and the fruits may be kept much longer. I have often seen bare places on a north wall that would have given a good return if covered with cordon Gooseberries. There are other methods of culture besides the cordon. We grow the plants trained to stout wires, the latter supported by Oak posts, and the whole covered with wire netting. The trees are 6 feet apart between the rows; grown in this way they give a wonderful return. For years our Gooseberry crop on bush trees, in spite of fish netting and every attention, was not reliable, as it was almost impossible to keep finches and other birds from the buds. They do more harm early in the year than when the fruits are ripe, and although at the start protection as described may be rather expensive, the outlay is soon recovered by the splendid crops secured. An expensive protector need not be employed. In country districts I have seen excellent results from very cheap methods. In the gardens at Knoyle House, near Salisbury, I noticed a very efficient fruit protector made by using Larch poles, the ends in the earth being creosoted. They were about 7 feet out of the ground, and covered with netting.

The Gooseberry may also be grown as an espalier. I have seen them grown thus, and made like a hedge to divide the flower from the kitchen

&c., and in the *Gardeners' Chronicle*, November 8, 1902, page 344: "Mr. S. T. Wright reported that the large, immense-cropping Damson shown at the previous meeting by Messrs. Veitch had been cooked and found of first-rate quality. The variety, to be known as the 'Langley Bullace,' &c., was granted an award of merit."

In *THE GARDEN*, November 22, 1902, page 357, "A. D." has a note headed "A Valuable Bullace," in which he says: "The fruits of this very fine Bullace (although called a Damson, which it hardly is) when shown at the Drill Hall by Messrs. James Veitch and Sons last month, now named Langley Bullace, having been cooked and favourably reported on by Mr. S. T. Wright, obtained an award of merit, &c."

Now, in the issue of *THE GARDEN* for the 5th inst., page 302, "A. D." writes, saying: "To describe it as a Bullace is absurd. It is really a Plum, as its parentage, Farleigh Damson and Black Orleans Plum, indicates, &c." I am afraid "A. D." contradicts himself, and the fruit committee is entirely responsible for the name. C.

ORCHIDS.

CELOGYNE CRISTATA.

PLANTS that bloom during the winter months have a particular value. This is one of the merits of *Celogyne cristata*. Few Orchids are more lovely than a well-flowered plant of this. Another recommendation is the simple culture it needs. It can be grown with other plants or with fruit trees during the summer months. It thrives equally well in large or small pots and pans. We grow them in pans. Our method is to grow them in a warm house with other plants during spring and early summer, and in autumn they are given an airy place in a fruit house. Here the bulbs ripen and the foliage matures. At the close of the year some of the plants are removed to a warm stove, which soon induces the flower-spikes to push up, and by the first week in February the blossoms are open. The specimen, of which I send a photograph, had about thirty racemes, some having five blooms each. The plants increase rapidly, the bulbs soon becoming crowded. Our method is to divide a portion every year; thus they only remain three years undisturbed. In this way we have always some well-established plants. Remove the old and crowded bulbs at potting time, i.e., when flowering is over and before growth commences. We grow them in fibrous peat, two parts, and one part of turfy loam and sand, with some charcoal mixed in, providing ample drainage. This permits our giving abundance of water during their growth. By careful management they may be had in flower some time. In a dry, warm air the blooms last a long time and do not become spotted, which they are apt to do if allowed to remain in a moist air.

Forde Abbey.

J. CROOK.

WORK FOR THE WEEK.

TREATMENT OF ORCHIDS DURING FOGS.

GROWERS who have the good fortune to live in the country know very little of what town growers have to experience from the dense sulphuric fogs, which play such sad havoc with most flowers and buds. In many parts fogs are very prevalent, but they do not leave the glass of our houses black, neither are all our flowers ruined if the necessary precautions are taken. It is advisable to get the houses as dry as possible as soon as the fog is visible. Shut all ventilators, and reduce the amount of fire-heat that is required when the ventilators are open. So long as the fog lasts do not water any plants or damp down the houses. It will be needful to have the outside of the houses washed near towns as soon as possible after the fog has lifted if the sooty sediment is deposited. Although this must seem rather heart-breaking work, it is absolutely essential for the well-being of the inmates, which under the best of conditions feel more or less the absence of strong light and sunshine during winter.

VANDAS AND AERIDES.

Very little water will be required by these for the next four months. If they are kept well damped between the pots when the atmospheric conditions permit sufficient humidity will be produced to maintain them. I do not believe in allowing the surface moss to become dry enough to kill it. We find by judicious damping during the winter months that the surface moss takes up sufficient moisture to preserve it. When we get very severe weather, entailing much fire-heat, and the atmospheric condition does not allow of much damping, it may be necessary to water enough to moisten the surface moss. They are best in a humid position in the stove house where there is sufficient buoyancy to maintain a sweet atmosphere. The popular *Vanda cerulea* should be placed in a cooler temperature such as the coolest part of the intermediate house, otherwise the same treatment should be given.

CELOGYNE CRISTATA AND ITS VARIETIES.

The growing season being now over, the supply of water should be considerably reduced, only giving enough to prevent shrivelling of the pseudobulbs. When the flowers begin to develop it will be necessary again to increase the water, but at that season they should not be watered till they become fairly dry. Place them in a light position in the intermediate house.

ANGULOAS.

This interesting section will by now have fully matured their new bulbs, and will be benefited by a thorough rest. It is essential during the resting season that a very light place be found for them in such a temperature as the cool intermediate house affords. Although the plants themselves require to be kept very dry, it is helpful to keep the surroundings damp from time to time. That will be ample to maintain them in a sound state if the new bulbs have been well finished.

LYCASTE SKINNERI.

The flower-buds on this most popular Orchid are now in evidence, and it will be to their advantage if they are well exposed to the light in the cool intermediate house. As the flowers approach development the surroundings must be kept somewhat dry to prevent the flowers getting spotted through damp. Any plants that have not made good growth should have the flower-buds removed as soon as they appear. If they are potted in good retentive compost water will be only necessary when they have become dry.

Gasston Park Gardens, Reigate.

MISCELLANEOUS.

A NEW TUBER IN FRANCE.

THE following interesting information is taken from the Journal of the Board of Agriculture for October: A species of tuber of the Potato family, not previously cultivated in Europe, has recently been introduced into France, where its experimental cultivation appears to have been attended with considerable success. The tuber in question, known as *Solanum Commersonii*, was obtained from Uruguay by M. Heckel, Director of the Colonial Institute at Marseilles, and specimens were distributed by him to various cultivators, one of whom, M. Labergerie, has communicated to the Société Nationale d'Agriculture de France an interesting account of the experiments carried out by him since 1901.

The specimens received by M. Labergerie included two distinct types of *Solanum Commersonii*, differing from one another in a marked degree. One of these, which may be taken to be the original type, produced suckers, and the tubers were deeply buried and distributed in all directions. The second, a violet-skinned variety, produced tubers clustered round the foot of the mother plant, and partly above ground. The tubers, moreover, of the first were found to possess a bitter flavour, while the second had, on the

contrary, a sweet taste. The origin of this variety is unknown, but it was suggested to the society by M. Schribaux that it was not merely a spontaneous variation, but the result of a natural cross between the *Solanum Commersonii* and the *Solanum tuberosum*, or ordinary Potato. The correctness of this suggestion cannot be confirmed, as it has not been found possible to produce such a cross artificially.

With regard to the original type, it is stated that when once established in the soil the plant perpetuates itself by its underground roots, and subsequent planting is unnecessary. Its flowers, which are very abundant and of a pale violet colour with a shade of yellow, emit an odour similar to Jasmine. The tubers are white with a yellowish skin, and have at first a markedly bitter flavour, but they were found to improve with cultivation, and in two years the proportion of good and eatable tubers increased by 10 to 20 per cent. So far, however, as these experiments have gone they have, in the majority of cases, been found too bitter for human consumption, but their improvement, it is said, promised to be very rapid. They are willingly consumed by animals, especially when cooked, and on the wet and marshy soils, which appear well adapted for their cultivation, they might form a valuable food for stock. A yield of about 6½ tons per acre was obtained in 1902, and about 4½ tons in 1903, on a fertile soil, but without any manuring or cultivation beyond a single hoeing when the shoots first appeared. The subsequent very abundant growth was sufficient to choke all weeds.

The tubers are rich in starch, and may prove valuable as an industrial plant. A successful attempt was made experimentally to employ the flowers for the production of perfume, and it was also found that the fruit, though not abundant, contained the perfume in a more concentrated form.

Besides the above original type, three variations have been observed, one of which promises to be of importance. Among the plants distributed in the first instance it was noticed that one was characterised by stronger stalks, and at the foot of the stalk two tubers of a blackish violet colour formed, which were very dissimilar to the tubers described above. These were found to be very sweet and fine flavoured, with a hardly perceptible bitterness. The tubers produced by this plant were carefully preserved and planted separately. In this variety the plant forms a central stem, with numerous branches and exuberant vegetation. Flowers were not abundant, and on some plants they were entirely wanting; they had no odour, and seemed to be sterile. The tubers form round the central stem. They vary in colour: when young they are white, gradually becoming rose-coloured, and finally violet. The flesh is usually white or yellow; the flavour is said to be perfect, in their young state they are sweeter than the best Potatoes with a slightly aromatic flavour; when fully grown they preserve their sweetness with a tinge of bitterness, but the aromatic taste is more pronounced.

The soil apparently most suited to the cultivation of this variety is damp or even wet, the cultivation being similar to that of the ordinary Potato, except that in order to avoid drying the soil ridging is not desirable. Harvesting is easy owing to the position of the tubers, and owing to the abundance of the foliage a single hoeing is sufficient. The yield obtained is apparently very large, being equivalent on the small area planted to about 40 tons per acre. The tubers are much appreciated by stock.

PLANTING OF FRUIT TREES ON CLAY SOIL.

At a time when fruit trees are being planted it may not be amiss to call attention to a method that has recently been practised in some parts of Germany, with, it is said, conspicuous success. On strong clay soil it is known that the roots of trees often suffer through lack of air, and this difficulty may be largely avoided by interstratifying the soil beneath the roots with layers of hedge brushings or similar material. A hole, 2 feet to 3 feet deep and twice this in width, is first made, in the bottom of which some 6 inches of

brushings are placed. On this a layer of soil of similar depth is deposited, then another layer of brushings, and, finally, the tree is set in and secured in the usual way. Trees so treated are said to make very vigorous growth, and to have great power of resisting drought and other prejudicial influences.

SOCIETIES.

PLYMOUTH CHRYSANTHEMUM SHOW.

THE Chrysanthemum show that was opened on November 1 in the Plymouth Guildhall was decidedly above the average of late years, although some slight diminution was noticeable in the number of cut blooms staged. The stands were throughout of a high order of merit. Mr. F. S. Vallis in the open classes and Sir Reginald Pole-Carew in the Devon and Cornwall classes being particularly fine. Fruit provided an exhibition in itself, over 1,200 dishes being staged, which contained splendid specimens of Apples and Pears. Vegetables also were well shown, the mammoth examples astounding the public by their size. Chrysanthemum groups, groups of miscellaneous plants, Orchids, greenhouse plants in variety, and floral decorations, comprising shower bouquets, wreaths, crosses, &c., added considerably to the display, as did the stands contributed by several nursery firms.

PRIZE LIST.

Forty-eight Japanese blooms: First, Mr. F. S. Vallis, with a splendid and faultless stand of huge blooms in the best condition.

Montigny was one of Calvat's new seedlings sent out this year, and was a splendid bloom, measuring 12 inches across and 8 inches in depth. The broad, loosely incurved petals were clear pale yellow in colour. This bloom received a special award as the best exhibit in the show. Mr. Vallis stated that he had three blooms on his plant, the other two being equally as fine as the one exhibited. It is a variety that evidently cannot be excelled when well grown. The stand received the West of England Chrysanthemum Society's certificate of merit; second, Mr. G. W. Drake, with a stand of fresh blooms that would have been equal to taking premier honours in most exhibitions; third, Mr. J. R. Gulson.

Twenty-four Japanese blooms: First, Mr. F. S. Vallis. Six Japanese, white: First, Sir John Shelley. Six Japanese in variety: First, Mr. J. R. Gulson. Eighteen Japanese, distinct, in vases: First, Mr. B. H. Hill; second, Mr. J. E. C. Boulds; third, Sir John Shelley. Twelve sprays of single Chrysanthemums: First, Mrs. A. Reed.

DEVON AND CORNWALL DIVISION.

General Sir R. Pole-Carew was first for twenty-four, twelve, and six Japanese blooms, and for six Japanese incurved, Lady Buller winning several second prizes.

Six vases Japanese, three flowers in a vase: First, Mrs. Bainbridge.

Group of Chrysanthemums: First, Mr. G. Soltan-Symons, with a fine and varied collection of splendid flowers.

For a miscellaneous group of stove and greenhouse plants Messrs. J. Webber and Sons were first with a collection comprising *Lilium longiflorum*, *Tuberose*, *Clivias*, *Bouvardias*, *Orchids*, *Ericas*, *Cyclamen*, *Begonias*, *Pelargoniums*, and *Chrysanthemums*, set off by *Palms*, *Crotons*, *Caladiums*, *Dracenas*, *Asparagus*, and *Maidenhair*; second, Mrs. J. C. Dormer.

FRUIT AND VEGETABLES.

In Apples and Pears Sir John Shelley carried off the bulk of the prizes, closely followed by Mr. J. R. Gulson, while among the other winners were General Sir Reginald Pole-Carew, the Earl of Mount Edgumbe, the Earl of Morley, the Rev. S. Baring Gould, and Lady Buller.

Mr. F. R. Rodd won the chief prizes for Grapes, and the Earl of Morley carried off first prize for a collection of salads. In vegetables the chief prizes were won by Mr. B. H. Hill and Sir John Shelley.

NON-COMPETITIVE EXHIBITS.

Among the nurserymen's exhibits the Devon Rosery Company, Torquay, staged a fine collection of Roses cut from the open ground, including the lovely Frau Karl Druschki, Augustine Guinoisseau, Viscountess Polkestone, Grüss an Teplitz, Rubens, Pink Rover, Victor Hugo, La France, Charles Darwin, Boule de Neige, Mme. Falcot, G. Nabonnand, Mme. A. Chatenay, Sunset, Mme. Lambert, Bouquet d'Or, Mrs. Sharnan Crawford, and many others, also a fine assortment of Apples and Pears.

Messrs. R. Veitch and Son, Exeter, had an interesting stand containing Violets Luxonne, La France, Princess of Wales, Marie Louise, Perle Rose, Baron Rothschild, sulphurea, St. Helena, Mrs. J. Astor, and Admiral Avellan, *Cyclamen*, *Gloriosa superba*, *Pancratium macrostaphana*, *Nerine Fothergillii*, *Bouvardias*, including King of the Scarlet, *Amaryllis Belladonna speciosa purpurea*, *Senecio pulcher*, *Romneya Coulteri*, *Carnations*, *Nierembergia filicaulis*, *Echeveria farinosa*, *Veronica gloriosa*, *Physalis Franchetti*, *Rhododendron Princess Alexandra*, the crimson fruit of *Thiandina dubia*, *Euonymus europaeus albus* fruiting, *Magnolia Lennel*, as well as *Chrysanthemums*, Apples, and Potatoes, amongst the latter being the famous Eldorado.

Messrs. T. Chalice and Son, Plympton, had the new *Smilax asparagoides myrtifolia*, *Nephrolepis Piersoni*, also a novelty; *Ruellia macrantha*, *Plumbago capensis*, *Orchids*, *Lily of the Valley*, *Epiphyllums*, and varied foliage plants.

Mr. N. Lewis, Bridgewater, exhibited a collection of Michaelmas Daisies. Mr. H. Hodge, St. Austell, staged a quantity of exceptionally fine tuberous *Begonia* blossoms, double and single, some of the latter being 6 inches across.

Mr. Vincent Slade, Taunton, showed a representative collection of the newer zonal *Pelargoniums*, including *Mary Beaton* and *Snowstorm*, white; *Duke of Norfolk*, crimson; *The Sirdar*, brilliant scarlet; Mrs. Simpson, white with pink eye; *Winston Churchill*, crimson, white centre; *Lady Curzon*, flesh-pink; *Ian Maclaren*, apricot-pink; *Raspail Improved*, double Jacoly, Mme. Carnot, double white; *Pasteur*, double, flesh-pink; *M. Haste*, double pink; and the curious scarlet *Fire Dragon*.

Messrs. Sutton and Sons exhibited their newest Potatoes, which were awarded a certificate of merit. Messrs. Saunders and Biss, horticultural builders, Exeter, showed specimens of their patent glazing, together with albums containing photographs of glass houses erected by them.

TORQUAY CHRYSANTHEMUM SHOW.

ON the 3rd inst. the Torquay District Gardeners' Association held a Chrysanthemum show in the large hall of the Bath Saloon in that town. The display was decidedly above the average of recent years, though cut blooms were not so numerous as was the case fifteen years or more ago, when, under the management of the defunct horticultural society, a large array of stands, filling an entire room, was annually exhibited. The quality of the exhibits, in cut blooms, specimen plants and groups, was, however, distinctly good, and miscellaneous plants, table decorations, arrangements in *epergnes*, baskets, and vases, together with numerous nurserymen's exhibits, contributed in producing a particularly bright and effective show. The association has, fortunately, tided over the period of financial depression which three seasons ago considerably marred its programme, and good and numerous prizes were offered, which produced keen rivalry amongst exhibitors.

PRIZE LIST.

Cut blooms, twenty-four Japanese: First, Mr. J. R. Gulson; second, General Sir Reginald Pole-Carew; third, Mr. J. N. Whitehead.

Twelve Japanese: First and certificate of the National Chrysanthemum Society, Mrs. Bartholomew; second, Rev. W. P. Alford; third, Dr. J. Quick.

Six Japanese: First, Mr. E. H. Price; second, General Sir Reginald Pole-Carew; third, Mr. J. R. Gulson.

Six Japanese, incurved: First, Colonel Cary; second, Miss Congreve.

Four vases of three blooms: First, Mr. J. N. Whitehead; second, Colonel Cary; third, Mr. S. B. Cogan.

Six Japanese, white: First, Mr. J. N. Whitehead, with Mrs. J. Lewis; second, Colonel Cary, with finer blooms of *Elsie Fulton*; third, Rev. W. P. Alford, with Mme. G. Henri.

Six Japanese, yellow: First, General Sir Reginald Pole-Carew, with splendid F. S. Vallis; second, Mr. J. N. Whitehead, with the same variety; third, Mr. J. R. Gulson, with the same.

Six Japanese, any other colour: First, Rev. W. P. Alford, with W. R. Church; second, Dr. J. Quick, with Mrs. Barkley; third, Mr. J. N. Whitehead, with Godfrey's King.

Twelve Japanese, incurved: First, Mr. J. R. Gulson; second, Mr. J. N. Whitehead; third, Dr. J. Quick.

Epergne of cut Chrysanthemums: First, Mr. F. Perrett, with a graceful arrangement; second, Mr. G. Emmett.

Vase of cut Chrysanthemums: A large class. First, Mr. F. Perrett; second, Mr. J. N. Whitehead; third, Mr. G. Emmett.

Table decoration: First, Mr. G. Emmett, with a pleasing arrangement of sprays of small, orange-brown Chrysanthemums and flowers of *Tropaeolum tuberosum* set off by *Maidenhair* Fern, *Asparagus tenuissimus*, and flowering Grasses; second, Mr. W. Minifie, with pink Chrysanthemums and white *Marguerites*; third, Mr. F. Perrett, with pink and white winter-flowering *Begonias*, arranged with *Eulalia zebrina* and *Selaginella*.

Basket of autumn foliage and berries: First, Mr. G. Emmett; second, Mr. W. Minifie; third, Mr. W. H. Damarell. In every case in this class the arrangement was far too crowded.

Group of Chrysanthemums: First and certificate of the National Chrysanthemum Society, Mr. Dundee Hooper; second, Captain Tottenham; third, Colonel Gardner; fourth, Mrs. C. Wise.

Three specimen single Chrysanthemums: First, Dr. J. Quick; second, Mr. W. H. Bulleid; third, Colonel Gardner.

Three specimen Chrysanthemums: First and silver medal of the National Chrysanthemum Society, Captain Tottenham, with three exceptionally good plants; second, Colonel Gardner; third, Mr. Dundee Hooper.

Six flowering table plants: First, Captain Tottenham; second, Dr. J. Quick; third, Colonel Gardner.

Six foliage table plants: First, Dr. J. Quick; second, Captain Tottenham; third, Mr. F. C. Simpson.

Six Ferns: First, Colonel Cary; second, Miss Congreve.

Six winter-flowering *Begonias*: First, Dr. J. Quick.

Special prize for six vases of cut Chrysanthemums in six varieties: First, Mr. W. P. Baynes; second, Colonel Gardner; third, Dr. J. Quick.

Fruit and vegetables were very good, many splendid specimens of the latter being staged. The silver cup for the best collection of vegetables was won by Mrs. Lambhead.

In nurserymen's exhibits the Devon Rosery Company, Torquay, showed a large stand, the chief object of interest in which was a collection of about 800 blooms of Roses culled from the open in their own gardens, among the chief varieties being *Souvenir de la Malmaison*, *Victor Hugo*, *Pink Rover*, Mrs. Sharnan Crawford, Mrs. R. G. Crawford, *Dupuy Jamain*, Mme. Victor Verdier, *Ulrich Brunner*, *Ma Capucine*, General Jacquemont, The Queen, Grüss an Teplitz, Viscountess Polkestone, Clara Watson, *Bouquet d'Or*, La France, Mrs. John Laing, *Enchantress*, *Corallina*, Mme. Lambert, *Eugenie Lamesch*, *Marie Raby*, *Duke of Wellington*, and W. A. Richardson. Besides the Roses the stand contained a group of pot plants of *Aster grandiflorus* in full bloom, *Salvia splendens*, *Cyclamen*, *Cypripediums*, *Acacias*, *Ericas*, *Begonias*, *Chrysanthemums*, and foliage plants. The same company's fruit farm staged a fine collection of Apples and Pears, Grapes, Tomatoes, Cucumbers, Mushrooms, Cape

Gooseberries, Chillies, *Capsicums* (yellow and red), and a punnet of Strawberry St. Antoine de Padoue, as well as sprays of flowering Laburnum.

Messrs. W. B. Smale and Son, Torquay, showed the new *Lobelia tenuis*, which promises to prove an excellent bedding plant; *Dracena Doucetti* and *D. Pallieri*, two variegated novelties; a representative collection of *Cactus Dahlias*, including *John Burns*, crimson; Mrs. Edward Mawley, yellow; Premier, scarlet, very narrow petals; *Violetta*, magenta; Khaki, orange-buff; *Florodora*, crimson; *Red Rover*, W. G. Baldwin, Florence, J. H. Jackson, and many others.

Messrs. R. Veitch and Son, Exeter, showed *Andromeda arborea*, the new *Hypericum patulum* Henryi, greenhouse *Acacias*, *Sarracenas*, *Iberis saxatilis*, *Ceanothus Gloire de Versailles*, *Veronicas*, *Grevilleas*, fruiting *Pernettyas* and *Bolbies*, and many other plants, as well as good collections of Chrysanthemum blooms and Apples.

Mr. W. H. Allward, Torquay, had a bright stand, and Mr. J. Heath, Kingskerswell, showed a collection of Violets, embracing all the newest varieties as well as the old favourites.

ROYAL BOTANIC SOCIETY'S SHOW.

THE last exhibition of the year was held on the 9th inst. in the corridor and large conservatory. There was not a large number of outside exhibitors present on this occasion, but a splendid show of Chrysanthemums and a collection of economic and medicinal plants, with produce manufactured from them, made this exhibition one of the most interesting of the season.

Messrs. Thomas Ware (1902), Limited, Feltham, Middlesex, had a fine collection of alpine and choice hardy plants, including *Saxifragas*, *Shortia galacifolia*, *Gaultherias*, *Helianthemums*, *Lithospermums*, &c. A Wallflower called *Early Paris* was stated to have flowered within two months of date of sowing. *Asters* were also shown in variety, prominent was *A. grandiflorus*, of good habit, and a rich blue colour (award of merit). Chrysanthemums were very effective, and again proved the mildness of the present season by being taken from plants growing in the open (large silver-gilt medal).

Messrs. Ambrose and Co., Cheshunt, staged a fine group of foliage and flowering plants, comprising *Palms*, *Ferns* in variety, *Dracenas*, *Carnations*, notably the new variety *Fascination*, of a bluish colour (award of merit), and several other varieties, *Lilies of the Valley*, *Cyclamen*, *Liliums*, and Chrysanthemums, all combined to produce good effect. The seedling *Grape Melton Constant* was shown in good form (award of merit). Gold medal.

Messrs. Champion and Co., City Road, E.C., showed several new designs in Oak and Teak tubs for shrubs, &c. Vote of thanks.

Messrs. W. Wood and Son, Wood Green, N., exhibited their patent pot-washing machine, which is a distinct advantage over the present method of washing pots. Certificate of merit.

The economic and medicinal plants shown by the society from their collection in the gardens were *Sarsaparilla*, *Coffee*, *Olives*, *Prickly Pear*, *Winter Bark*, *Cinnamon*, &c. Examples of fibre-producing plants were the *Bowstring Hemp*, *Sisal Hemp*, and "Ramee." In most cases the manufactured articles, together with raw fibre, &c., were shown in connexion with the plants. The botanical experiments arranged by the Practical Gardening School showed the effect of various coloured rays of light on plant growth. Apparatus for recording the rate of growth, the water contents, and carbon and mineral contents of certain popular garden plants were on view.

ASCOT CHRYSANTHEMUM SHOW.

IN the Grand Stand the annual autumn show was held on the 9th and 10th inst. Competition was keen in nearly all classes; cut blooms were numerous and good; groups of Chrysanthemums and miscellaneous plants were quite features of the show; fruit and vegetables excellent.

Of cut blooms, the leading class was that for eighteen incurved and as many Japanese. The leading prize was a silver challenge cup.

Mr. Ashman, gardener to C. T. D. Crews, Esq., Billingbear Park, Wokingham, was first with heavy Japanese and irregular incurved; Mr. W. Wilson, gardener to Mrs. Christie, Tubsden, Winklesham, second with better incurved but weaker Japanese.

In a class for twenty-four Japanese, distinct, Mr. Wilson won with medium sized fresh examples of popular varieties well staged; Mr. W. Jinks, gardener to L. J. Drew, Esq., Knowle Green House, Staines, was a close second. For twelve distinct Japanese, Mr. G. Lane, gardener to Miss Ridge, Highfield, Englefield Green, was first with a capital set; Mr. W. Barnes, gardener to A. F. Walter, Esq., Bearwood, Wokingham, was a close second.

Six blooms, any one white flowered variety, was a strong class. Mrs. J. Dunn, full, graceful, and pure in colour, won for Mr. G. Lane first prize; while Mme. C. Tragleackers won second place for Mr. Wilson. In a similar class, for six any other coloured variety, Mr. G. Lane secured the first prize with F. S. Vallis; Mr. Wilson following with Bessie Godfrey. Mr. G. Lane had the best six vases, three blooms in each, among four competitors.

Incurved varieties were especially numerous and of good quality. Mr. W. Jinks won for twenty-four distinct with medium sized, neatly dressed examples of popular varieties; Mr. Wilson was a decidedly close second with large but slightly rougher examples. In a class for six any one variety, there was keen competition. That popular variety C. H. Curtis won both first and second prizes for Mr. Ashman, and Mr. Baskett, gardener to E. W. Beckett, Esq., Woodlea, Virginia Water.

Single-flowered varieties were a feature, staged in vases, three spikes each of six varieties. Mr. W. Neate, gardener to Miss Thacker, Queen's Hill, Ascot, was first; Mr. F. G. Pearce, gardener to F. B. Rendle, Esq., Forewood, Ascot, second.

An attractive class was that for twelve blooms arranged in a basket with any foliage. Mr. J. Sargent, gardener to Dowager Lady Lucas, Heatherwood, Ascot, secured the premier award with an unusually showy exhibit; Mr. Barnes second.

Groups of Chrysanthemums and foliage plants were not numerous, but effective, arranged down the middle of the room. Mr. W. Lane, gardener to Sir E. Durning Lawrence, M.P., King's Ride, Ascot, won the coveted honour with plants carrying good blooms and effectively interspersed with suitable foliage plants; Mr. J. Sargent second. Mr. W. Lane also had the best group of Chrysanthemums only, huge blooms, quite fresh and good foliage, with an effective arrangement.

Naturally grown, nondisbudded plants arranged in a semi-circular group were a distinct feature and well shown by Mr. White, gardener to the Dowager Marchioness of Conyngham, The Mount, Ascot, and Mr. G. Sargent, both excellent groups, in the order here given. Mr. W. Lane won first place for an interesting group of miscellaneous plants, Orchids, Palms, Crotons, Ferns, and Clerodendron fallax, all nicely blended; Mr. J. Sargent second.

CROYDON CHRYSANTHEMUM SHOW.

CROYDON held its seventeenth show in the large Public Hall on the 25th and 26th ult. Owing to pressure on our space we have, unfortunately, been obliged to hold over the report until now. Japanese blooms in vases made a splendid display, and the groups, too, were good. We are glad to see that this society is encouraging the exhibition of the flowers in vases instead of on boards; probably it will not be long before the boards are entirely done away with. Mr. Beckett, the secretary, works hard for this horticultural society, and is to be congratulated upon the success of the show, which the President thought the finest they had had.

The first prize (a challenge cup), the leading class, that for thirty blooms, fifteen Japanese and fifteen incurved, was won by Mr. Bille, gardener to Count Hatzfeldt, Chippenham. Mr. Salter, Woodhatch Gardens, Reigate, was second. The silver cup, given as a first prize for twenty-five Japanese blooms, was won by Mr. Salter. Mr. Lane, gardener to E. V. Coles, Esq., Caterham, being second. Mr. W. Collins, Engadine Gardens, Park Hill Road, set up the best group of Chrysanthemums in pots. Mr. Cook, Shirley, being second.

In the amateurs' classes Mr. N. Wrightson, Addiscombe, won the silver cup presented by Mr. James Epps, jun., for ten blooms of Japanese, distinct, in vases. Mr. R. E. Mason, Croydon, won the second prize (a silver medal). Mr. Burgess, Merton, being third and taking the bronze medal. Mr. Wrightson also showed the best six Japanese blooms. Mr. W. Philpot sent the best Pompons. The most attractively arranged table decoration, Chrysanthemums only, was set up by Mrs. A. Robinson, Wallington.

Of gardeners living within the borough of Croydon Mr. Mills was the most successful; he was first for a group of plants, for ten Japanese blooms, and for twelve Japanese blooms. Mr. L. Gough showed the best six Japanese flowers. The finest dessert Apples were from Mr. O. Jeal, Mr. J. Johnson being second.

In the open classes for fruit, the best twelve dishes of Apples were shown by Mr. Bille. Mr. J. D. Simmonds, Tandridge Court Gardens, being second. For six dishes of Pears Mr. Bille was also first. The best bunches of black Grapes were staged by Mr. Lintott, and Mr. W. Manzey, gardener to A. Benson, Esq., Reigate, showed the best white. Mr. Bille, who seemed practically invincible, was again first for a collection of twelve kinds of vegetables, Mr. Lintott being second.

The best Japanese bloom in the show was one of the variety Henry Perkins, from Mr. Mills; the best incurved was Mme. Ferlat, shown by Mr. Bille.

Among the many non-competitive displays that added so much to the general interest and effect of the exhibition were: Fruit from Messrs. J. Cheal (Crawley), Ambrose and Son (Cheshunt), and John Kiebler; Chrysanthemums from Messrs. Wells and Co. (Earlsfield), W. Turner (Croydon), H. Brazier (Caterham); Carnations from Messrs. Cutshaw, &c.

CORN EXCHANGE CHRYSANTHEMUM SHOW.

ON Wednesday, the 9th inst., a Chrysanthemum show in aid of the funds of the Corn Exchange Benevolent Society was held at the Corn Exchange Tavern, Mark Lane.

The schedule comprised nine classes, the first four being open to members of the corn trade only, four more being open to amateurs, non-members of the corn trade, and one class open. There was fairly good competition in most of the classes, and the prizes, besides being money, included two silver cups, each of the value of £5 5s.

For twelve blooms Japanese, distinct, Mr. F. W. Smith was first with a nice lot of bright well set-up blooms, comprising F. S. Vallis, Mrs. Barkley, Henry Perkins, General Hutton, Geo. Lawrence, and others. Mr. W. R. Clark came in second. The next class was also for twelve blooms, but half were to be Japanese and half incurved. Mr. F. W. Smith was again first, and Mr. W. R. Clark second. In the winning stand Mme. Carnot was very fine, and Lady Isabel, Countess of Warwick, W. R. Church, Mrs. G. Mileham, Beatie Godfrey, &c., were good examples. Six cut blooms of Japanese, distinct, were shown by Mr. G. M. Edwards, who was placed first for a board containing Mrs. W. Mease, Mafeking Hero, Queen Alexandra, Geo. Lawrence, Mrs. H. Hamilton, and Mr. T. Carrington (?). The second place was occupied by Mr. F. W. Smith. For six blooms, half incurved and half Japanese, Mr. F. W. Smith and Mr. W. R. Clark were placed in the order named.

A very fine stand of twelve distinct Japanese came from Mr. E. Mocatta in the non-members' division, and he was awarded leading honours for grand specimens of F. S. Vallis, Mafeking Hero, Mme. C. Nagelmackers, Mme. Carnot, Florence Penford, Henry Stowe, G. Lawrence, Mrs. E. Thirkell, Mrs. F. W. Vallis, Lady Conyers, Henry Perkins, and General Hutton. Mr. C. T. Cayley came in second. There were six competitors in this class, Mr. James Preece showing a capital twelve.

In the other classes the principal winners were Messrs. H. J. Sequerra, E. Mocatta, C. D. Cooper, and F. W. Smith.

The open class was for six cut blooms, distinct, staged in vases. Mr. E. Mocatta and Mr. F. W. Smith put up some capital exhibits, and were first and second respectively.

Donations of Orchids, Carnations, &c., were received by various patrons, all of which were sold after the show for the benefit of the funds of the Benevolent Society.

PEOPLES PALACE CHRYSANTHEMUM SHOW.

A CHRYSANTHEMUM show was held in the Queen's Hall at the People's Palace, Mile End Road, on Friday and Saturday, the 11th and 12th inst. The exhibits, especially those from the members—living, as they do, in one of the most crowded districts of London—were interesting from many points of view. A liberal schedule was provided, prizes ranging from 2s. to 25s., and the competition was keen, there being a good many entries in most of the classes. Friends of the society sent exhibits not for competition, Mr. Leopold de Rothschild's handsome group of foliage plants, Bamboos, Lilies, Chrysanthemums, &c., being much admired. Mrs. C. B. Hayward and Messrs. Hollies, Limited, sent cut Chrysanthemums, as also did Mr. F. A. Bevan. A nice collection of Apples was staged by Mr. C. E. Shea. Vases, baskets, epergnes, &c. were well shown, and a stall for the sale of cut flowers, the proceeds to go to the London Hospital, was also provided.

In the competitive classes among the members we noticed the following varieties as those most freely shown: F. S. Vallis, Mme. G. Debie, Mrs. Barkley, Mme. Herreweghe, M. L. Remy, Mme. Carnot, Mme. Gustave Henry, M. Pankoucke, Phœbus, Ma Perfection, Iolene, C. H. Curtis, Countess of Warwick, &c.

Some good groups were also staged of plants in pots. Altogether this is a most useful society, and is doing excellent work in the district. The secretary, Mr. R. H. West, and committee are to be congratulated on the result of their labours among the poor people of Mile End, whose advantages are very few from a horticultural point of view, and yet are made so much of both at this and the summer show.

DUMFRIESHIRE AND GALLOWAY CHRYSANTHEMUM SHOW.

THIS show was held in the Mechanics' Hall, Dumfries, on the 10th inst., Mr. W. J. Herries Maxwell, M.P., presided at the opening ceremony, which was performed by Miss Daisy Johnstone-Douglas, Coulongan Castle. The show showed a remarkable advance upon that of last year, and the cut blooms particularly were good. In the open classes for cut blooms the principal winners were Messrs. G. Fairbairn and Son, Carlisle, who showed capital blooms, though some were small. Messrs. James Service and Sons, Maxwelltown, Dumfries, were also successful exhibitors. In the gardeners' classes for cut blooms the most successful competitor was Mr. James Henderson, Elmbank, who secured the silver medal for the greatest number of points in these classes. Mr. Henderson showed remarkably well all through, and carried off all the first prizes, his closest competitor being Mr. J. Duff, Threave, Castle-Douglas. In the plant classes the leading prize was for a circular group arranged for effect, and here Messrs. James Service and Sons repeated their success of last year with an excellent group of plants. Mr. James Houston, Crichton Royal Institution, was second. The other plant classes contained nothing specially noticeable, except Ferns, table plants, and a magnificent specimen plant of single Chrysanthemum, Miss Rose, 5 feet in diameter, which was awarded a certificate of merit in addition to the first prize in its class. It was shown by Mr. James Henderson.

Fruit and vegetables were well shown, and the Apples were remarkably good. Mr. J. Duff won with Grapes; Mr. J. M. Stewart had the best collection of Apples, Mr. J. Duff being second. Mr. J. M. Stewart was first for Pears. Mr. Stewart had also the best collection of vegetables, and other successful exhibitors in these classes were Mr. K. Mackenzie, Conheath, Dumfries; Mr. J. Duff, and Mr. A. Duff, Maxwelltown. In the special classes interest centred in that for the best twelve Japanese blooms, the judges, after careful scrutiny, finally awarding the prize to Mr. J. Houston, with an excellent stand of fresh blooms, Mr. J. Duff coming second, and Mr. J. Henderson third. Miss L. Rutherford, Crichton House, had the best epergne of Chrysanthemums, her exhibit being very tastefully arranged.

Messrs. G. Fairbairn and Son showed florist's decorative work of great beauty and Chrysanthemum blooms; Messrs. James Service and Sons a large number of varieties of Potatoes; and Mr. James Kerr, Dumfries, twenty varieties of new seedling Potatoes, raised by his late father, Mr. W. Kerr, and himself.

DULWICH.

THIS show was held at the Baths, East Dulwich, on the 8th and 9th inst. The beautiful display made by the numerous exhibitors on the above dates should be very encouraging to the executive. Almost all the classes were well filled, and an interesting feature was the great number of successful exhibitors. At local shows it too often happens that a limited number of exhibitors take all the leading prizes, but this was not the case at Dulwich. The groups of pot plants are always a great feature here, and there being several different classes for these, it ensures a great display. There were about twenty good groups.

In the class for six specimen bush plants there were four competitors. The first prize went to Mr. S. Martin, gardener to W. Harvey, Esq., who had good plants of Val d'Andore, Lady Hanham, Miss Mildred Ware, Viviani Morel, and others; second, Mr. W. A. Hurst, gardener to A. F. Fitter, Esq., Streatham, in whose exhibit Mrs. Greenfield and Miss Nellie Pickett were good; third, Mr. W. Webster, gardener to W. Higgs, Esq., Clapham, who also had very creditable plants. In the open class for a group of plants, Mr. A.

Winter, gardener to E. Manwaring, Esq., took first honours with a well-arranged group of plants with fine blooms; second, Mr. E. Houlton, gardener to J. F. Gardiner, Esq.; third, Mr. E. Rea, gardener to R. S. Tilling, Esq., Herne Hill.

The classes for blooms shown in vases were a great feature of the show. In that for four vases, three blooms in each, Mr. A. Winter was first with fine blooms of F. S. Vallis, Mrs. Mease, Australia, and Mme. Carnot; second, Mr. T. Martin, gardener to W. Harvey, Esq., Dulwich; third, Mr. C. Bellis, gardener to Mrs. Faulkner. For a vase of seven blooms in variety the first prize was won by Mr. G. Rouse, gardener to J. S. Halliday, Esq., Dulwich, who had very fine blooms; second, Mr. A. Winter; third, Mr. H. Tindall, gardener to G. Hatch, Esq.

For a vase of incurved, five blooms, one variety, Mr. A. Winter was first with beautiful blooms of Duchess of Fife; second, Mr. E. Rea, with fine blooms of C. H. Curtis; and Mr. W. A. Hurst was third with the same variety. For a vase of five Japanese blooms, one variety, Mr. A. Winter was first with massive blooms of F. S. Vallis; second, Mr. T. Martin, with the same variety; third, Mr. C. Bellis, for good blooms of Florence Penford. In a class for one Japanese and one incurved bloom with foliage, the first prize was gained by Mr. A. Winter with Duchess of Fife and F. S. Vallis, this bloom also gaining an extra prize for the finest bloom in the show; second, Mr. T. Martin; third, Mr. C. Bellis. In a class for six bunches of singles the first prize was gained by Mr. G. Duncan, gardener to R. Wiseman, Esq., with some very pretty blooms of Elsie Neville, Crown Jewel, Admiral Symonds, and Koupel Beauty; second, Mr. J. Sibley, gardener to A. Carson Roberts, Esq., who had very similar blooms; third, Mr. G. Rouse. In a class for twenty-four blooms (sixteen Japanese and eight incurved) there was only one entry, Mr. A. Winter taking the first prize with a very good lot of blooms. In the incurved blooms W. Higgs, Mrs. F. Judson, Duchess of Fife, and C. H. Curtis were good; the Japanese included fine blooms of G. Mileham, Mme. Paolo Radaelli, and F. S. Vallis. In a class for twelve Japanese, on boards, Mr. Winter was again first; second, Mr. T. Martin; third, Mr. Bellis. In a class for six Japanese blooms, Mr. Haselgrove, gardener to W. Brander, Esq., Sydenham Hill, was first; second, Mr. A. Hurst; third, Mr. J. Richards, gardener to W. Pierson, Esq., Herne Hill. In a class for six incurved blooms Mr. Winter was first; second, Mr. T. Collins; third, Mr. J. Sibley. In a class for six Anemone-flowered, shown in vases, Mr. T. Martin was first; second, Mr. J. Sibley.

For a basket of Chrysanthemums, arranged with foliage, Mr. A. M. Fakner was first with a good arrangement of yellow and bronze blooms; second, Mr. J. Sibley, with some pretty singles and doubles, yellow and white; third, Mr. G. Duncan. In a class for an epergne Mr. C. A. Young was first; second, Mr. H. J. Williams; third, Mr. A. M. Fakner. In a class for an epergne (ladies) Mrs. Wolfe was first; second, Mrs. Allen. For a basket with foliage the honours went to the same ladies. The floral arrangements were hardly equal to last year.

All the amateur classes were well filled, and many of the exhibits were of excellent quality. In the non-competitive class Messrs. Peed and Son, Norwood, put up a very pretty group of bright blooms, and were awarded a silver-gilt medal. The same award was given to Mr. R. Foster, Nunhead Cemetery, who had a fine group of plants.

Mr. Norman Davis showed some splendid Japanese blooms on boards, Beauty of Leigh, Mme. Paolo Radaelli, Marshal Oyama, Lady Curzon, Guy Hamilton, Maurice Rivoire, and Roi d'Italie being specially fine.

STIRLING CHRYSANTHEMUM SHOW.

THE annual show of the Stirling Chrysanthemum Association was opened in the Public Hall, Stirling, on the 10th inst. by the president, Mr. Greeme A. Whitelaw of Strathallan Castle, and was continued on the 11th inst. The show was much the largest and finest yet held by the association, and the improvement was noticeable in practically all departments. It may be observed, however, that the quality of the exhibits in the classes for the cut blooms was remarkably close, and that only half a point decided the leading prize—that for the President's Cup, which was won by Mr. G. Stewart, Tulliallan Castle, with twenty-four splendid blooms of Japanese in eight varieties, three in each vase. Mr. Stewart's victory is very creditable, close as it was, for his next rival was the celebrated grower, Mr. D. Nicoll, Rossie; Mr. W. Waldie, Dollarbeg, another first-class grower, being third.

The Corporation of Stirling Cup for four vases of Japanese, with three blooms each, was won by Mr. J. Birse, Breinham Park; Mr. G. H. Pearson, Viewforth, being second; and Mr. W. Watt, The Lea, Bridge of Allan, third. Other leading winners in the cut bloom open classes were Mr. J. Wood, Dunmore Park; Mr. A. Morton, Blairdrummond; and Mr. J. MacDonald, Castle View.

Plants were good, as a rule, the leading winners with these being Mr. J. Wood, Mr. J. Birse, Mr. W. Watt, and Mr. R. Jenner, Newhouse. Bouquets, vases, and epergnes were generally of great beauty, the leading winners being Mr. J. Waldie, Mr. J. Wood, Mr. T. Fraser, and Mr. R. Jenner. In the classes for other plants than Chrysanthemums Mr. T. Lunt, Keir, who did not exhibit in the Chrysanthemum classes, carried off the bulk of the honours, but Mr. J. Birse, Mr. L. M. Leen, Alloa, and Mr. J. J. Wann, Kennet, were very successful also. The fruit classes were excellent, and the leading winners were Mr. T. Lunt, Mr. J. Waldie, Mr. J. J. Wann, and Mr. A. Morton. Vegetables were capital, Mr. D. McNeill, Mr. J. Waldie, Mr. M. Carrigan, and Mr. D. McNeill being the most successful. Amateurs showed well in their classes.

There were several non-competitive exhibits, that which attracted most attention, perhaps, being Messrs. G. Bonyard and Co.'s collection of Apples, Messrs. W. Drummond and Sons' stove and greenhouse plants and conifers, Mr. John Craig's plants and wreaths and bouquets, and Messrs. D. and W. Croll's stand of plants.

THE GARDEN

No. 1723.—VOL. LXVI.

NOVEMBER 26, 1904.

THE PRESERVATION OF WILD PLANTS.

AT the monthly dinner of the Horticultural Club, held recently, Professor Boulger gave an extremely interesting address relating to Gilbert White's Natural History of Selborne and the Selborne Society, which has been founded for the preservation of wild plants and animals in honour of that renowned naturalist and in sympathy with his pursuits. Although inevitably the light of later knowledge has revealed many errors in Gilbert White's assumptions, and the field in which he worked was extremely limited, his history still remains and ever will remain one of our most prized classics in every library worthy of the name. He has been described as "a lens exquisite in definition but of small field," and every Nature lover knows how valuable is such an instrument, and how much more capable it is of investigating Nature's secrets and marvels than one of wide but superficial range. It is due to this minuteness of record and unbiassed adherence to facts that his book has been handed down in about ninety editions from generation to generation as a model, and is now obtainable in so many forms. The secret of success in his case may be epitomised in the rule "to use one's eyes and never despise the smallest trifles." No small merit, indeed, must a man have possessed for his area of experience, the little and remote village of Selborne, five miles from a railway, to remain after two centuries the bourne of innumerable pilgrimages of Nature lovers all the world over.

The Selborne Society, founded by Mr. G. Musgrave, and of which Professor Boulger is the spokesman as editor of *Nature Notes*, is doing invaluable work in the line it has selected in fostering laws and regulations for the protection of wild plants, &c., from the extermination which threatens them and by providing a recognised record of naturalistic observation as far as possible on Gilbert White's own lines. In the discussion which followed the address many suggestions were made as to the best means of checking that vandalism to which is due the imminent extermination of many of our plants not merely rarities, but also normally abundant ones, such as the Primrose and many of our Ferns. The point of the whole matter appears to be a lamentable tendency to regard these treasures as merely so many sources of pounds,

shillings, and pence. Cases were mentioned of persons who were professional naturalists staying for weeks together by the habitats of rare plants and butterflies, and collecting them ruthlessly to the point of extinction in order to sell them to stay-at-home collectors for their herbaria, &c. Some even were criminal enough to destroy what they did not need in order to enhance their rarity, and so increase their selling value. The refusal by the Press of all advertisements tending to encourage the rooting up of plants by rural villagers was strongly advocated. The holiday-making Fern collector was also mentioned as a vandal in most cases, denuding Ferny habitats ruthlessly, only to dump the spoil into unsuitable places and thus to practically destroy them.

One speaker mentioned a practical method of counteracting the evil by collecting the seed of remaining rarities and scattering it freely about the natural habitats. *Campanula rotundifolia* was re-established on one of our London commons in this way, after finding but two or three survivors where it was once recorded as abundant.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

LILACS AND LILIES OF THE VALLEY.

From Lily Nursery, Dersingham, King's Lynn, Mr. T. Jannoch sends some bunches of Fortin's Lily of the Valley, from retarded crowns, and some sprays of Lilac Marie Legraye, cut from "etherised" plants. Both were very fine indeed. Mr. Jannoch makes large use of ether in forcing Lilacs, and to judge by the flowers sent he is most successful in their treatment.

FLOWERS FROM SOMERSETSHIRE.

A welcome lot of flowers comes from Mr. Crook, Forde Abbey Gardens, Chard. *Gloriosa superba* grandiflora was exceptionally fine, the colouring remarkably bright and cheery. This is a very good form, and special note must be made of Mr. Crook's red form of *Primula obconica*, the colour

being very rich and unusual. *Salvia splendens* grandiflora, the red-flowered *Schizostylis coccinea*, and the well-known Source d'Or outdoor Chrysanthemum were in this gathering. Our correspondent remarks: "Seldom do we see the scarlet *Salvia splendens* grandiflora flowering beside white and other Chrysanthemums. These with the *Schizostylis* make the garden bright in mid-November. Chrysanthemum Source d'Or is still one of the best for the open garden and to cut from."

PHOTINIA SERRULATA.

Mr. Magor sends from Lamellen, St. Tudy, Cornwall, flowering shoots of *Photinia serrulata*, with the following instructive note: "Enclosed are flowers of *P. serrulata*, which is, perhaps, more notable for its bright red shoots in very early spring than for its flowers. It is a native of Japan and China, and should be planted in a rather sheltered spot, as the young leaves, which are its chief attraction, are apt to get torn by the wind. Here it has formed a large bush over 20 feet high, and is just coming into full bloom."

SCHIZOSTYLIS COCCINEA.

Mr. T. B. Field, Ashwellthorpe Gardens, near Norwich, writes: "I am sending for your table flowers of *Schizostylis coccinea*, which is one of the most useful plants we have at this time of the year. A sunny position should be chosen for it. I have seen it growing well at the base of a south wall. The plants require breaking up and replanting every second year, and any manure it may be considered needful to give should be applied on or near the surface, in order to discourage a rank growth. The blooms sent were taken from plants growing on a north border. If frost is not too severe flowers may be looked for almost till Christmas."

HYDRANGEAS FROM NORTH WALES.

Mr. Roberts, The Gardens, Tan-y-bwlch, North Wales, sends a box of interesting flowers of blue Hydrangea, the scarlet *Salvia*, and a beautiful Chrysanthemum, Queen of Whites: "I cannot resist sending up a few blooms of Hydrangeas, although somewhat faded in colour, illustrating as they do their value as autumn-flowering shrubs of much merit in mild districts. You may perhaps imagine the effect they produce here either in great single bushes or in irregular groups of scores together; solid masses of beautiful bloom. They have been really quite a sight for some months, and are so even now. *Salvia splendens* grandiflora and Chrysanthemum Queen of Whites are used extensively here in many ways for producing a late autumn display, and are effective anywhere, but I think the most striking bit of colour we have at present is on an irregular, comparatively level patch on the summit of one of our many massive rocks with pieces of rock cropping up here and there. The *Salvias* and Chrysanthemums were mixed among *Azalea mollis*, the rich autumnal tints of the foliage of which brightened up the greenery until the former became conspicuous. The two associate well together, and are now, with their immediate surroundings, a very pretty and refined picture, but alas! the first nip of frost will destroy, and as yet we have had none this autumn, but fear it is not far off, for as I write the surrounding hills are white with snow. Can you or

some of your correspondents and readers give me the name of a Chrysanthemum the counterpart of Queen of Whites in colour, habit, flower form, and style of flower, vase-like and elegant, but which comes in brilliantly in the middle of September; and also a bright scarlet *Salvia* that will bloom at the same time. *Salvia* Scarlet Queen is a trifle earlier than *Salvia splendens grandiflora*, but would like one still earlier and as showy. This particular bed was attractive earlier in the summer with hundreds of late-planted *Lilium longiflorum*, sparsely interspersed with clumps of the annual *Lupinus* in their various colours and a dash of *Polox Chequered* here and there, preceding which, of course, were the *Azalea* blooms intermixed with late spring-flowering plants, so it has been a bright spot for a long season. We hope some reader will help our correspondent.—Ed.]

POTATOES TO EAT.

If the Rev. G. H. Engleheart and Mr. A. R. Goodwin (page 342) prefer a close, yellow Potato to a floury Windsor Castle or Up-to-Date they are welcome to eat it. But I know which is the more acceptable in ninety out of a hundred gardens. I said nothing about size of individual tubers, and I have never yet had to rely upon the judgment of the cook so far as quality in vegetables is concerned. The comparisons in both notes are, as Mr. Goodwin says, very amusing. Gros Colmar Grape is first introduced; why? Everyone knows that with the exception of Black Aurante it is more easily and cheaply grown than any other late Grape, and so it is produced by the ton to supply fruit of fair quality at a moderate price to those who cannot purchase Muscats at three, four, or five shillings per pound. Mr. Goodwin wants me to explain why *Beurre d'Chirgreau* Pear and Worcester Pearmain Apple are always in demand. They are, I suppose, bought by those who want a somewhat showy fruit at a reasonable price, and who cannot afford threepence or fourpence each for *Doyenne du Comice* or sixpence per pound for Cox's Orange Pippin, prices at which they have been respectively retailed in this neighbourhood. The inability to bring Muscat Grapes and the choicest Apples and Pears within the reach of the million is to be deplored. If the price is prohibitive what is to be done?

What connexion, however, there is between the fruits named on page 342 and Windsor Castle and Up-to-Date Potatoes I leave to the ingenuity of your contributors to discover; they are neither cheap, nor are they, from a Potato standpoint, of indifferent quality. On the contrary, they will tetch in midwinter, late winter, and early spring quite the top price; that is if they are a good level sample. Mr. Engleheart seems to be under the impression that Up-to-Date is favoured because of its size. Not at all. The retailer, whether in the shop or street, will not buy extra-sized tubers. How is it then that this Potato is always in request and the price is well maintained? I suppose they are not bought to look at. I did not claim for either Windsor Castle or Up-to-Date the acme of perfection in a Potato. I said they were in their respective seasons, both from the view of cropping and quality, about the best procurable. I fail to see anything "amusing" about a simple statement of facts. E. L. B.

P.S. I am quite aware that on some soils Up-to-Date comes very large, unshapely, and watery; but that is the fault of the cultivator, not of the Potato.

More has been said of late respecting the Northern Star Potato. As I have now had one or two tubers cooked I can speak more definitely than I could previously have done. With me it has cropped well, having only six tubers diseased in 16wt.; it also grows very late into the autumn. Certainly it was when cooked a fairly good table Potato, but, when classed with Sutton's Windsor Castle Potato and Reliance for quality, I consider it a long way behind these two. I never wish for a finer Potato than the last named; it does full justice to its name, is a very heavy cropper, and the quality when cooked is excellent. Anyone who has never given these two Potatoes a trial

should do so, and I feel sure they would be pleased with them. I have now tasted one or two others of recent introduction, but they are not so good as the above two varieties. Perhaps some other readers and growers will have a word to say respecting the Windsor Castle and Reliance Potatoes.

Rdg Gardeners' Correspondence.

J. S. HIGGINS.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

November 29.—Royal Horticultural Society at 1 p.m. Exhibition of Colonial-grown Fruit.

December 6.—National Amateur Gardeners' Association meeting.

December 8.—Annual Meeting and Dinner of National Rose Society; National Amateur Gardeners' Association, Annual Dinner.

December 13.—Royal Horticultural Society's meeting at the New Hall, Vincent Square.

The Rev. Professor Henslow.—It is with regret we hear that the Rev. George Henslow has resigned the secretaryship of the scientific committee of the Royal Horticultural Society, a position which he has filled for twenty-five years without pecuniary reward. Services so unselfishly given in the interests of scientific research and the society, at whose meetings his descriptive lectures have been appreciated for their clearness and simplicity, deserve the warmest praise. Mr. Henslow is removing from London to Leamington, but will, we are glad to say, lecture occasionally at the usual fortnightly meetings of the society. Mr. Chittenden is the secretary until the end of the year. At a meeting of the scientific committee recently the following resolution was unanimously passed:—"Resolved that: This committee, on hearing of the resignation of its secretary, the Rev. Professor Henslow, V.M.H., desires to place on record its sense of gratitude for the unvarying courtesy and marked ability he has shown in the disinterested discharge of his duties during a period of a quarter of a century. The committee trusts that, although the Professor is compelled by circumstances to retire from the regular duties of his office, it may still be able to profit by his experience and to welcome him occasionally at its meetings."

Patrinia villosa.—This Japanese perennial is a most beautiful autumn-flowering plant, suitable for the border or the wild garden. The leaves are dark green, three lobed, villose, and the flowering-stem reaches a height of 1 metre and more. The top of the stem and the branches form a large corymb covered with myriads of white sweet little blossoms, which last more than one month.

They are good for cutting purposes, as they will open in water. The rootstock sends out runners which will flower the next year. In the *Vomero* Garden they are cultivated in the full sun, and also in half shade.—WILLIAM MULLER.

The British Gardeners' Association.—The Bournemouth, Parkstone, Wimborne, and Highcliffe Gardeners' Associations held a special meeting in the Bournemouth Arcade on Tuesday, the 15th inst., to hear an address upon the objects of the British Gardeners' Association, by Mr. W. Watson, the hon. secretary. The chair was taken by Mr. Stevenson, superintendent of the Bournemouth Public Gardens, and about 100 gardeners were present, some having come a distance of fifteen miles by brake to attend the meeting. Mr. Watson sketched the history of the association up to the election of the present committee of selection, whose duties were, he said, limited to the

selection from applicants for membership of all who fulfil the conditions stated in the prospectus until 500 members have been elected, and in the meantime to take such steps as may appear desirable to ensure the success of the movement. One of these was to hold meetings of gardeners in centres throughout the country for the purpose of placing the aims and objects of the association clearly before those whose interests it was intended to promote. He then read the prospectus and explained those portions of it which had been misunderstood in some quarters, insisting on the necessity of limiting membership to those who were qualified by training and experience, and pointing out that the executive council of the association would be elected by the first 500 members who joined. It would then be within their powers to reconsider the existing rules and to make such additions and modifications as might appear desirable to meet the views of all sections. Adverting to the scale of wages, hours of labour, and other conditions of employment recommended in the prospectus, Mr. Watson said that a standard rate of pay, &c., was now fixed for all important industries in this country, and he saw no great difficulty

THE REV. PROFESSOR HENSLow, M.A., V.M.H.

in the way of fixing an acceptable scale for gardeners. When gardeners had got all that the prospectus recommended they would still be a hard-worked and moderately paid body of men. He believed that it would now be considered nothing short of a national calamity if the organisations which regulated the conditions of employment in the great industries were to cease operations. A resolution to form a Bournemouth branch of the British Gardeners' Association was carried by a two-thirds majority.

Eupatorium violaceum.—For the autumn this is one of the best plants that we have, and particularly as the sky blue colour is very rare at this season. It is a plant for every garden. The culture is similar to that of the *Chrysanthemum*, and if well grown it forms a good pot plant. The colour is light sky blue, and the flowers last fresh a long time when cut.—W. MULLER.

Apple Lady Sudeley.—With me this Apple is now a success, since it became thoroughly established—ten years planted. I grow twenty bush trees about 10 feet high. The main branches are kept thin and the summer growth low. A full exposure of the buds is necessary.—E. M.

Mr. William Bateson, F.R.S.—The Darwin medal of the Royal Society has been awarded to Mr. William Bateson, F.R.S., for his contributions to the theory of organic evolution by his researches on variation in heredity.

Winter Carnation Dr. W. G. Grace.—Some blooms of this variety have just come to hand from Mr. W. E. Boyes, Belvoir Street, Leicester. The flowers are large, full, of a bright scarlet-crimson colour, and highly fragrant; it is a strong grower, and appears to bloom with great freedom. Mr. Boyes has for a few years past been a careful raiser of winter-flowering Carnations, striving to obtain a vigorous growth in combination with high colour, quality of petal, freedom of bloom, and rich fragrance.—R. D.

Lettuce Continuity.—This is one of the most long-standing of summer Lettuces, and as a seed grower said of it during the past summer it will not bolt to seed. It grows to a good size, has a large solid heart, green, tinted with brown, and it is a great favourite with many gardeners for salading purposes. It is curious to note that the leaves of Cabbage Lettuces are much crisped: indeed, there are few smooth-leaved varieties, but there is scarcely a Cos Lettuce that has the leaves assuming the crisped form. There appears to exist a dislike to Lettuces which have their leaves tinted with yellow, one bearing the name of Buttercup has probably the greatest amount of yellow in its leaves. This is also a Cabbage variety.—R. D.

The newer Potatoes.—I have noticed with interest the letters that have appeared in THE GARDEN lately about the newer varieties of Potatoes. Last March I planted 3½ lb. of Evergood, some on the 18th and the remainder a week or two later, by way of an experiment. Those planted on the earlier date yielded a much heavier crop than those planted on the later date. From about 1 lb. planted on the 18th I had about 3 lb. or more of good sized tubers. From the 2½ lb. planted later I had about 4 lb. of tubers; these were not so large as the earlier ones. As to their eating qualities, I have always found them excellent, being white and floury. I may mention that the soil here is light, dry, and gravelly.—Miss A. SMALLPEICE, *Cross Lanes, Guildford.*

A note on Carnations.—At the Royal Botanic Society's show on the 9th inst., Messrs. J. Ambrose and Son, of Cheshunt, staged a large and interesting group of plants and flowers, and some fine varieties of Carnations were included. Of these Fascination, soft flesh pink, large full flowers, very fragrant, was particularly worthy of note, and gained a certificate of merit. Beauty was another very sweet scented variety, the large, full flowers with fringed petals stood up well on stiff stems, and were of the purest white; Floradora, rose-pink; Chivalry, deep crimson, were also good, and all had the characteristics of the American varieties, namely, strong stems, good perfume, and fringed flowers. Vulcan, bright scarlet, was good but devoid of scent, and in habit more like other English varieties.—A. H.

Lily bulbs from Japan.—Doubts have been more than once expressed concerning the supply of Lily bulbs this season from Japan, but up to the present the lamentable war in which that country is engaged does not appear to have had any particular influence on the crop and its harvesting, for we have had considerable numbers sent over, and no fault could be found with their general condition. On the 26th ult. a moderate consignment was disposed of at Stevens's rooms. It consisted entirely of *Lilium longiflorum*, and the bulbs were in good condition, while there was a brisk demand for them. On the 10th inst. Messrs. Protheroe and Morris had a large quantity to dispose of, the bulbs of *L. longiflorum* and its varieties alone amounting to nearly 500,000, while over 50,000 bulbs of *L. auratum* were also sold. Many of the *L. longiflorum* bulbs were bought

by the large wholesale dealers, and it is very probable a goodly proportion of them are destined for retarding purposes, for which this Lily is so well suited. It is always the first to reach here in large quantities from Japan, as the growth is completed earlier than that of *L. auratum* or *L. speciosum*, which three species form the bulk of the Japanese Lilies that come to this country. The bulbs of *L. auratum* sold on the 10th inst. were not so fine as those which we may reasonably expect later on, for they presented the appearance of having been lifted somewhat prematurely. At all events, there did not appear to be the least difficulty in disposing of over 2,700 cases of different Lilies on that one day.—H. P.

Chrysanthemums at Arundel House, Dumfries.—There is generally an excellent display of Chrysanthemums in the gardens of Arundel House, Maxwelltown, Dumfries, the residence of Mr. John Primrose, and this year the flowers are quite up to the high average of former years, and many excellent large blooms might be exhibited. Among the best this year have been Mme. P. Radaelli, Lady Crawshaw, Bessie Godfrey, W. Seward, Guy Hamilton, Lady Violet Beaumont, Nellie Pockett, Jessie Cottle, Mme. Georges Bruant, Scottish Chief, Lord Ludlow, and Vivian Morel. Mr. J. Allan, Mr. Primrose's gardener, is a believer in firm potting, and is extremely successful in securing dwarf plants, clothed with foliage down to the pot, and splendid flowers of exhibition standard. A number of small-flowered varieties are also cultivated for decorative effect.

New Apples recently shown by Mr. Ross.—Those who saw the results of the efforts of one man, after many years of patient labour and care, would thoroughly agree with the honour bestowed by the Royal Horticultural Society, the fruit committee awarding the Hogg Memorial Medal, which is only given on rare occasions, and for special fruit culture. My note on the above will necessarily be brief, as the interesting account of Welford Park Gardens on page 309, and the pleasing account of Mr. Ross's good work, leave little room for further remarks. I more refer to the interesting exhibit at Westminster on the 1st inst. There were eighteen distinct varieties, and though some were naturally much better than others, so many were really good that it must have been a gala day for Mr. Ross, who has done so much to improve hardy fruit, and who has raised such varieties as Charles Ross, Rival, Welford Park Nonsuch, Atalanta, and The Houblou, with others that will in time become standard dessert and cooking varieties. The latest addition is Hector MacDonald, and Mr. Ross thinks this will be one of his best seedlings. It is a fruit of good appearance and quality. It bears well, and should become a great favourite. It is rarely that a private gardener can see the results of his work as Mr. Ross has done, and though advanced in years, he is still quite as enthusiastic as he was forty years ago. We heartily congratulate him.—G. WYTHES.

Marguerite Carnations in November.—Carnations in November may sound rather out of season, but as they are out of doors it will not be denied, I am sure, that they are very welcome. They were very beautiful last week in a garden I had the pleasure of passing through. Stone pans filled with them made a delightful show even in mid-November. Undoubtedly both summer and autumn have been favourable for their growth and continued flowering, but it shows how valuable this annual is. The seed was sown in February under glass; the seedlings were transferred to pots when large enough, subsequently hardened off, and finally placed pretty closely together in the stone vases and pans. It is no exaggeration to say that a few days ago these plants were bearing hundreds of flowers, and they had been in bloom since the beginning of August. The colours come fairly true from seed. The scarlet, purple, and white appeared to be particularly good; the two former were rich, distinct colours. They were most effective as seen on the stone balustrade in front of the house, and nothing could well be more attractive so late in the year, when most plants suitable for vase decoration are

over. I should like also to mention what a good plant for vases outdoors in late autumn *Salvia splendens* is, and how very bright and welcome in the flower garden.—Y. Z.

The value of Alyth Strawberries in 1904.—The returns for the season of 1904 having now been received, the secretary and treasurer of the Alyth Fruit Growers' Association, Mr. A. M. Ferguson, has remitted to the members cheques for their respective shares of the returns. The consignees of the Strawberries paid carriage, and the net rate paid to the members, after deduction of all expenses, is £31 19s. 7d. per ton.

"Evolution."—At the usual lecture in Broughty Ferry, under the Horticultural Association and Technical Education, on the 10th inst., the lecturer was Mr. David Storrie, F.R.H.S., of the firm of Messrs. Storrie and Storrie, Dundee and Glencarse. Mr. Storrie chose for his subject "Evolution," one which he treated in a thoroughly competent and instructive manner. Both the vegetable and animal kingdoms were included in Mr. Storrie's lecture, which was illustrated by a series of lantern slides. Mr. James Slater, president of the Horticultural Association, presided over a large and deeply interested audience. Mr. Storrie was warmly thanked.

Russelia juncea.—This *Russelia* is a very pretty and graceful flowering plant, which serves to render the stove or intermediate house gay with its bright coloured blossoms during the latter part of the summer and well on into the autumn; indeed, sometimes until winter. It belongs to the natural order Scrophulariaceae, and is therefore a near ally of the Pentstemon and Calceolaria, but the general aspect of the plant would in no way suggest this, for the branches are slender and Rush-like, while the small narrow leaves are few in number. The flowers, which are borne freely along the slender pendulous shoots, are individually about 1 inch long, tube-shaped, and bright scarlet in colour. This *Russelia* is a native of Mexico, from where it was introduced in 1833. It needs a fairly light soil, and will thrive in a mixture of equal parts of loam and peat or leaf-mould, with a liberal sprinkling of sand. As a specimen plant in a pot it is seen to great advantage when a few of the principal shoots are each secured to a neat stake, and the others allowed to dispose themselves at will, the appearance of the plant when at its best then suggesting a floral fountain. It may, besides this, be trained to a rafter in a small structure, as then the pendulous shoots hang down like a living fringe, while it is also suited for growing in a suspended basket. A second species (*R. sarmentosa*) is more of a climbing habit, and M. Lemoine of Nancy has raised two or three hybrids between this species and that above-mentioned.—T.

Chrysanthemums at the Royal Botanic Society's Gardens.—Although exhibitors were few at the show on the 9th the conservatory and corridor were bright with Chrysanthemums grown in the gardens. All the various types were well represented, some of the singles being particularly attractive. Ladysmith, pink, both in masses and dotted about was very pretty; Mary Anderson, white with a faint blush tint—good plants of this placed about among foliage plants were very pleasing; Miss Edith Pagram, rose-pink; Miss Annie Holden, yellow; and many others were worthy of note. Among the Japanese sorts the flowers were not of great size, but the colours were bright and varied. Mathew Hodgson, bright red, with a yellow shading, one of the very best for decorative work; Kimberley, bright yellow, was flowering freely; Mrs. Barkley, though often seen with immense blooms, is equally pretty under moderate treatment, and flowers freely. A whole host of pretty things might be enumerated. The plants grown this season number upwards of 3,000. It is a new departure for the society to grow so many, and they certainly add much to the attractiveness of the large conservatory.—H.

Pear Beurre Alexandre Lucas.—This handsome Pear is less grown than its merits deserve. Few fruits that have been introduced promise better in our light soil; indeed, in this respect it more resembles Beurre Diel, as it rarely fails to crop. In appearance it is not unlike Beurre

Diel, but a little longer, has a lighter skin, and is of very good quality. The fruits are much perfumed, melting, very juicy, and of delicious flavour. When grown on the Quince stock it fruits freely, and does well as a bush or pyramid. Cordon trees bear excellent fruit: indeed, I think this mode of culture good for this variety, as it gives such handsome produce. I am not much in favour of the very large Pears, such as Pitmaston, for dessert; the one named does not come so large as the Pitmaston. Even when allowed to bear freely the fruits are not so large, but grown as a bush they are very handsome, the tree grows freely, and is worth space in all gardens where good Pears are required. As an exhibition fruit it is much liked; its season is November, but in the north I have had this variety good well into December when gathered late and given cool storage. It is well worth a wall where a late supply is required.—G. W. S.

Salvia Horminum.—The note on page 335 from D. S. Fish reminds me how very beautiful this plant was in a Worcestershire garden that I visited recently. Mr. Fish writes: "The typical *Salvia Horminum* has purple bracts, but a form exists with red ones, and in another they are white." Numbers of beds were filled with plants grown as the type, but the bracts showed great variation in colour. Some were purple, others quite blue, and some were white. Probably if I had looked more closely I should have found some that were red or reddish. Even on the same stem the colour of the bracts varied from deep purple to light purple, and also to blue. Nothing is more effective in the flower garden at this time of year; the colouring is bright, and also unusual, and together with the pretty grey leaves makes a charming picture. It may not be generally known that by cutting back the plants in early summer stronger growths are produced that will be in full beauty at a later date than if the stems are allowed to develop unchecked. This method is worth practising, even if only to provide a succession of the beautiful bracts. The difference in vigour between the growth of plants not cut back and those which were is surprising.—Y. Z.

Rust on Clivias.—In THE GARDEN of the 12th inst. you replied in your "Answer to Correspondents" column to a query about rust on *Clivias*, and stated that the probable cause was an error in culture. On Thursday, the 10th inst., Mr. Rogers, gardener to Mrs. Wrigley, Bridge Hall, Bury, read a paper before the Bury Horticultural Society on

"Spring Flowering Plants," during the course of which he mentioned *Clivias*, and referred to rust. He said that when he first observed rust he sent a specimen to Messrs. Kerr, Liverpool, and to the Scientific Society. The former stated the cause to be an error in culture, and the latter could not give the reason of its appearance. Mr. Rogers was not satisfied, and set about finding out the cause himself. He eventually found some very small insects (the name of which he did not give) which were only visible under the microscope or a very powerful lens. After trying many insecticides, but without effect, he decided to use Fowler's Gardener's Insecticide, which was the only one that would destroy the troublesome pest. He said the insecticide was to be applied to the crown of the plants and the axils of the leaves. This may be of use to your querist, and perhaps other readers.—RALPH LANDLESS, Bury.

SOUTH AFRICAN PLANTS.

THOSE who have been trying to acclimatise South African plants out of doors could hardly have had a better season for getting them established. In this garden, however, the growth if anything has been too exuberant, especially of late, and whether such succulent things as the Transvaal Daisy and perennial species of *Arctotis* will get through the sharp winter which is predicted is another question. Throughout the dry weeks of summer, until the welcome rains came at the end of August, all the South African Daisies, including *Mesembryanthemums*, made growth slowly, but developed quantities of buds and flowers. During the last two months, on the contrary, the bushes have spread enormously, and now look too soft to be altogether satisfactory. The Transvaal Daisy (*Dumorphothea Echlonis*) is still (November 3) covered with buds, which will scarcely have time to open. The pure white of its ray florets and the gem-like blue of the disc form a striking contrast to the dark shaded underside of the petals, and it is a very noticeable and charming plant. One never ceases to regret that, in common with all the South African composites, it has the habit of early closing. Cuttings strike with the same ease and in the same way as a *Pelargonium*—in sunshine. This is pre-eminently the case also with the different species of *Arctotis*. *A. aspera* has been a little disappointing this year, though not from any fault of its own. It was set too near the Transvaal Daisy, and the warm creamy tint of its flowers has clashed somewhat with the snow-white of its neighbour. The crinkled grey-green leaves of this *Arctotis* are so fine that we grow it as a foliage plant for the winter in the cold greenhouse.

Small-rooted cuttings of *Mesembryanthemums* tucked into the driest part of a wall early in May have hung a curtain of rose-coloured and glistening white flowers in front of it, and these still open every sunny day. The question is whether it would be better to cut the trailing stems well back to the wall, where the root-tufts seem strong and happy, or to leave them alone and await the result. Damp is the enemy to be dreaded more even than frost, and it is specially desired to save these plants for a second season, when they ought to be worth seeing. A point will be gained if it can be proved that *Mesembryanthemums* may be successfully grown in sheltered open spots in Sussex, as well as on the warmer west coast.

Sutherlandia frutescens, from South African seed, has grown tall and strong, but was planted out rather too late and has shown no disposition to flower. Its scarlet lobster-claw flowers, not unlike a miniature *Clianthus*, are a familiar feature of the Veldt, and are followed by bladder-like pods like those of a *Colutea*. It seems to be useless in the case of this plant, whether grown outside or in a greenhouse, to try to interfere with Nature by pinching or cutting back to improve its shape. No treatment of the kind, apparently, will turn it into a bush, for it persists in preferring length to breadth. Its slight wand-like growth is elegant, nevertheless, and in the spring the soft tops take root in pure sand with the greatest ease.

Oddly enough *Montbretias* have not flowered with the freedom they did in the wet season of last year. It may be that they have merely exhausted the soil and require a fresh site, but they have not been long in their present position. The best varieties are very beautiful, but almost all are terribly encroaching.

The length of time during which bulbs will remain dormant is an interesting point, but one which resists calculation. Bulbs of *Belladonna Lilies* planted in June under a warm wall have shown no sign as yet of starting, but are sound and safe. It is all the better in this particular case that the root-fibres should get thoroughly established before the leaves begin to show. In and out amongst the *Belladonnas*, a quantity of home-saved seed of *Anomatheca cruenta* was scattered as soon as it was ripe. The seedlings have come up strongly, and it is hoped that these two South African bulbs will make themselves at home in the warm sheltered spot chosen for them.

These notes of the behaviour of a few South African plants during the past season may be of use to other growers who are interested in them.

Hastings. K. L. D.

THE DOUBLE WHITE COLCHICUM (*C. AUTUMNALE ALBUM PLENUM*).

NOTES ON LILIES.

LILIUM TESTACEUM.

THE possibility of this Lily being a native of Europe, which is discussed by your correspondent S. G. Reid, page 322, reminds one how little we know of the origin or early history of one of the most beautiful members of the genus. It is generally regarded as a hybrid between *L. candidum* and *L. chalcedonicum*, but of this we do not seem to have any authentic particulars. The most complete account of the early history of *Lilium testaceum* that has come under my notice occurs in a book of 122 pages, entitled "Monographie, Historique et Littéraire des Lis, par Fr. de Cannart d'Hamale, Président de la fédération des Sociétés d'Horticulture de Belgique, &c," printed at Malines, 1870. Somewhat curtailed it reads as follows: "There is also another Lily with recurved petals, concerning the origin of which we have but a vague idea, but which, nevertheless, appears to be Japanese, viz., *Lilium testaceum* of Lindley (the Nankeen Lily). It was first discovered by M. Fr. Ad. Haage, jun., of Erfurt, accidentally in a large consignment of Martagons, which he had received from Holland in 1836, and with which it had been mixed. The plant was introduced into Belgium by L. Van Houtte, of Ghent, who had received a case full of it from M. Von Weissenborn, of Erfurt, in exchange for some Fuchsias. This exchange was made in 1840 or 1841, at which time there is no question that of this unknown Lily three persons of Lille in France each possessed an offset. One only of these offsets chanced to flower, at Esquermies-lez-Lille, and showed an umbel of pendant blossoms, with petals reflexed like the Martagons, but larger, and of a beautiful nankeen colour slightly tinged with rose, and dotted with a deeper tint at the base. The bright orange-coloured stamens served to add to the beauty of the flower. M. Van Houtte, who happened to be at Lille, was fortunate enough to see this splendid novelty. He eventually received from M. Von Weissenborn an order for Fuchsias, with a postscript in the following terms: 'If by any chance you want the nankeen-coloured Lily I have a quantity at your service.'

"M. Van Houtte did not think twice about it, and seized with avidity the good fortune offered to him. He accepted the exchange, and soon became the possessor of a case more than a yard square full of Nankeen Lilies of all sizes, the largest bulbs measuring more than a foot in circumference. This news soon spread to Lille, and there caused much talk and great disappointment when the possessors of the three offsets were convinced that the Lily of which M. Van Houtte had become the owner was the same as those which they guarded so jealously. The Nankeen Lily passed from Belgium to England, where it flowered for the first time in 1842 with Messrs. Rolisson. It was figured and described in the *Botanical Register* by Dr. Lindley in 1843, under the name of *L. testaceum*. Dr. Kuntze, of Halle, had described it as *L. isabellinum*, and it also bore the name of *L. excelsum* among gardeners. M. Rinz Senior, a nurseryman at Frankfurt, and another gardener at Leipzig, claimed to recognise in it an old friend which they had cultivated in their younger days. This was evidently a mistake, for no mention of this Lily has been made in any work on botany or horticulture. We are more inclined to believe that it is of recent introduction, and that the Dutch received it from Japan, with which country they were in constant communication. But is it really a true species? Or is it not rather the product of the white Lily fertilised by one of the Pomponium section? The general appearance of the plant would lead one to suppose so."

COLCHICUM SPECIOSUM MAXIMUM.

Such is the early story of this Lily, which interested me greatly, and as many readers of THE GARDEN are, like myself, admirers of these beautiful plants, they too may be interested. H. P.

THE FLOWER GARDEN.

SOME GOOD COLCHICUMS.

MEADOW SAFFRONS or *Colchicums* are, together with the autumn-flowering Crocuses, distinctly the most valuable of our bulbous plants that brighten the concluding months of the year with their blossoms. The common Meadow Saffron (*Colchicum autumnale*), which bears single, narrow-petalled flowers of a pinkish purple tint, looks well in the grass, as indeed do all the members of this family, but the rarer species are too scarce for planting except in tilled ground. As the flowers are produced in the autumn and the leaves do not follow until the succeeding spring, the blossoms have the bare earth for a setting, which somewhat detracts from their appearance, and it is therefore advisable to surface the ground in which they are planted with some dwarf, loosely-growing subject. I say loosely-growing, because I have found that a particularly close-growing carpeting plant, such as *Arenaria balearica*, is injurious to them.

Some time since I surfaced colonies of several *Colchicums* with this *Arenaria*, lifting large patches of it and fitting the patches together above the groups of Meadow Saffrons, so that they were entirely covered with an unbroken mass of green. This was done immediately the flowers died down in the autumn. I paid no attention to them in the spring, but, on looking at them in the summer, found that not a single *Colchicum* leaf had pierced through the carpet of *Arenaria*, but that a few had been produced around the edges of the green covering. I came to the conclusion that the

growth of the *Arenaria* was so close that it prevented the air from reaching the soil, and that this was the cause of the *Colchicums* failing to throw up foliage. I at once removed the *Arenaria*, but in the autumn the only flowers that were produced were a few where leaves had appeared round the edge of the *Arenaria*, in place of the many dozens that generally brightened the ground in the autumn. I have found the following species handsome and effective: *C. Bornmulleri*, very pale mauve-pink, height 10 inches, length of petal 3½ inches, breadth of petal 1½ inches. This is the earliest of the *Colchicums*, being at its best with me on September 5. *C. Sibthorpii*, a very pretty flower, light rose-pink, tessellated with darker markings, height 9 inches, length of petal 2½ inches, breadth 1 inch; September 8. *C. speciosum*, pale rose-purple, height 9 inches, length of petal 3 inches, breadth 1 inch; September 10. There is a white variety of *C. speciosum* which is very beautiful, but which is at present too expensive for the majority to possess.

C. speciosum maximum. — This, in my opinion, is the finest of all the *Colchicums*. Though said to be a variety of *C. speciosum*, I am inclined to think it a distinct species, as its foliage does not appear until that of *C. speciosum* is fully developed. Its flowers resemble a port wine glass in shape, whereas those of the type are more like a sherry glass in contour, the increased spread of the former rendering the blossoms far more striking, while, as their petals are of greater consistency, the flowers retain their beauty for a considerably longer period. In colour it is deep rose-purple, this tint contrasting well with the white base of the cup, height 9 inches, length of petal 3 inches, breadth nearly 2 inches; September 30. This *Colchicum* is very rarely met with, and I only know one nurseryman who catalogues it. *C. autumnale album plenum*. — Height 6 inches, pure white, flowers very double, about 5 inches across, petals long and strap-shaped, and half an inch in breadth.

Each bulb of this variety produces numerous flowers, so that a group of two or three dozen plants will bear 100 or more blossoms. Though a comparatively old introduction the plant is still scarce, bulbs being usually catalogued at 5s. each. The *Colchicums* named are all distinct, and form a handsome and representative selection.

S. W. FITZHERBERT.

SOME INTERESTING ANNUALS.

AMONG the numerous annuals which are cultivated in the open we would call attention to those mentioned below:

AGERATUM MEXICANUM (Imperial Dwarf).—The *Ageratums*, with their numerous little blue heads of flower, which last throughout the summer, are fairly well known. The dwarf variety of which we are speaking has not only the merit of being dwarf, but also of coming true from seed. Hitherto it has been necessary to preserve a quantity of dwarf plants throughout the winter in order to take cuttings from them in the spring, for seeds of the dwarf [forms] produced plants of very unequal

innumerable lilac-purple flowers. The *Callichoës* are seldom met with, yet they are beautiful and very easy to grow. *C. pedata* and *C. verticillata* with their bright and brilliant red flowers also deserve to be mentioned. They should be sown under glass or in a cool greenhouse about the end of March, and may be planted out from the beginning of May.

DIASCEA BARRERÆ.—This is another very interesting yet scarcely known annual. It is an elegant plant allied to the Snapdragons and Toadflax. It was introduced a few years ago from the south of Africa. It is very floriferous, and its flowers last a long time; they are of a rich red-brown colour. It is probable that, like the Snapdragon, this pretty flower would be improved in the hands of the hybridist, and that it would give birth to varieties of diverse and happy combinations of colours. Sow in March and April under glass, and plant out in a sunny spot in May.

ESCHSCHOLTZIA CALIFORNICA ERECTA COMPACTA.—*E. californica* of to-day is dwarfer than it used to be. The flowers are upright, and are borne on stout stems. All the *Eschscholtzias* are annuals

to be grown everywhere: *Apollo* and *nanus* compactus, the dwarf and tufted forms; *Diadem*, pale yellow, with discs almost black, and its sub-variety with double flowers; *Stella*, golden-yellow, the best of all; and *Orion*, a most brilliant yellow. They may be sown in the open or scattered broadcast among groups of shrubs in April and May.—JULES BURVENICH, in *Le Bulletin d'Arboriculture*.

TREES AND SHRUBS.

BEAUTIFUL DECIDUOUS TREES FOR SMALL GARDENS.

AS the planting season has again come round it may not be out of place to call attention to the above subject, especially as many of the choicer deciduous trees seem as yet comparatively little known. They are more adapted, however, to the requirements of small places than our large native trees, and it is matter for regret that this fact is not more recognised in the laying out of such

gardens, for excellent as they are in their proper place, it is neither right from a landscape point of view nor in any way convenient to have pleasant little nooks dwarfed and smothered by huge Oaks, Elms, or Beeches.

Magnolia tripetala is a capital subject as a background for a small lawn; it will attain in a fairly sheltered situation a height of from 20 feet to 30 feet. The flower is larger than that of *grandiflora*, but looser and the petals less firm and solid. With the exception of *M. macrophylla*, I suppose *tripetala* is quite unique in foliage, the individual leaves often attaining a length of 16 inches. The Virginian Bay (*Laurus Sassafras*) is grand as an isolated specimen; it is about 30 feet high, and forms quite a regular pyramid with very dense, handsome foliage that is slightly scented. The Maidenhair Tree is perhaps better known than either of the foregoing, but is not planted so much as it deserves to be, for it must be borne in mind that, like the large-leaved *Magnolias*, its foliage is, so far as tree life is concerned, practically unique. I think the Siberian Crab (*Pyrus prunifolia*) a very handsome tree, and as it almost invariably grows into a shapely specimen, it can, like the Virginian Bay, be highly recommended; so also can the Apple-shaped Service and the *Paulownia*. Descending a little in the scale so far as height is concerned, we come to a number of interesting subjects that might with advantage be used in lieu of the countless *Laburnums*, *Almonds*, *Thorns*, &c., that meet one at every turn. I fancy *Benthamia fragifera* might be relied on to form a handsome tree on a small scale. From

occasional notes from the south-west of England it would appear to attain there considerable dimensions, and the few plants we have are very fair specimens, notwithstanding the fact that they have been seriously handicapped by poor hungry soil and the close proximity of common things of vigorous habit. The wood of this tree is excessively hard. I had occasion to remove a few branches last winter, and found, to use a common expression, it was like cutting at stone.

Magnolia glauca is a handsome little tree or large shrub, and the flower is pleasing with its faint Tea Rose-like perfume. *Asimina triloba* is not often met with, but deserves a place in all collections, if it were only for its very singular flowers. The Fringe Tree (*Chionanthus virginicus*) is quite a little tree with us, and attracts general attention when covered with its delicate sprays of bloom. Two handsome trees that may be associated with the above named to give variety of foliage are *Corylus purpurea* (the purple-leaved Nut) and *Prunus pissardi*. Among the trees of larger growth mentioned at the commencement of

COLCHICUM BORN-MULLERI.

growth. *Ageratum mexicanum* is therefore a great improvement. All that is necessary is to sow seed in March in pans in a forcing frame or greenhouse, and to prick out the seedlings in April into small pots for the final planting out in May. This variety, with flowers of a clear, pleasant blue, has already given rise to a sub-variety with white flowers, which is also worthy of commendation.

AMARANTUS CAUDATUS.—This is a very old annual, which was much better known in times past. It is gradually disappearing from gardens, although it is as beautiful as it is peculiar and easy to grow. The inflorescences, commonly called "Fox-tails," last a long time, and have a very charming effect in front of masses of greenery. We should like also to call attention to another—*Amarantus sanguineus*—which has long inflorescences of a deep blood-red. Sow the seed where the plants are to flower in April and May. Although the plant succeeds even in the poorest soil, a rich soil improves the size and duration of the flowering stem.

CALLIHOE LINEARILoba.—This is a charming dwarf malvaceous plant with small foliage, bearing

belonging to the Poppy order, and are of much interest for several reasons. In the first place, they can be safely sown in the open air from the second fortnight in April; in the second, they will succeed anywhere; thirdly, their flowers last long and are striking and brilliant. There are single and double, pure white, pale carmine, pink, red, orange, &c. The most remarkable of them all is undoubtedly *E. Mandarin*, which has large and beautiful bright orange flowers.

GLAUCIUM FLAVUM TRICOLOR.—This is a species of the same family as the *Eschscholtzia*. It is accommodating as to soil and temperature, and is also most ornamental. It should be sown in the open in April. Its glaucous foliage is very pleasing from the first, and is in striking contrast with the large and vivid orange-red flowers.

HELIANTHUS CUCUMERIFOLIUS (*Orion*).—These little Sunflowers have become very popular, and the skilled hybridist has effected several improvements in the type already distinguished by its beautiful yellow, long-stemmed flowers, so well adapted for vases. The following varieties deserve

these notes I might have included the *Cornus brachypoda*. This is comparatively new, but ought to prove a valuable addition to our small ornamental trees. I do not claim for the above short list of some eighteen or twenty sorts that they are greatly superior to many others; they are simply a few that have come under my personal notice, and can be relied on to give satisfaction in the planting of small pleasure grounds. E.

TREES & SHRUBS WITH COLOURED FOLIAGE.

(Continued from page 341).

In the following list most of the shrubs which have any just qualification to be placed under this heading are included.

ACANTHOPANAX SPECIOSUM VAR. *VARIEGATUM*.—This is a bushy Araliad, with small, golden variegated leaves; its culture outdoors should be confined to the warmer parts of the country.

ACER.—In this genus several very useful plants are to be found, the following being a selection of the best. *A. campestre* var. *pendulum* foliis variegatis and *A. campestre* variegatum are both white variegated forms of our common Maple. *A. dasycarpum* var. *foliis albo-variegatis* is a white variegated-leaved form of the silver Maple; its leaves are very pretty when they first develop, but get burnt before summer has far advanced. *A. d.* var. *lutescens* has yellowish leaves, the colour being most marked when the leaves are young. *A. japonicum* var. *aureum* makes a bush with golden leaves, while *A. j.* var. *rubrum* has deep red leaves. *A. Negundo* furnishes several very useful varieties which may be grown either as standards or bushes. *A. N.* var. *foliis marginatis aureis* has pretty golden leaves, while *A. N.* variegatum, with white variegated leaves, is a well-known plant. *A. palmatum* brings us to a species composed of a large number of pretty foliated varieties, which are collectively called Japanese Maples. Very many of these are seen at their best when grown under glass; but the varieties *A. p. septemlobum sanguineum* and *atropurpureum*, which have deep red leaves, do very well out of doors. *A. platanoides* var. *marginatum album* is a variety of the Norway Maple, with green and cream-coloured leaves, the cream predominating. It is very pretty early in the season, but gets burnt in bright sun. *A. Pseudoplatanus* var. *atropurpureum* has purplish leaves. *A. P. flavo-marginatum* has golden and green variegated leaves; this is commonly called the Corsicorpine Plane. *A. P. foliis albo-variegatis* has leaves striped with whitish lines, while *A. P.* var. *Prinz Handjery* has pretty golden variegated leaves.

(To be continued.)

THE ROSE GARDEN.

EXHIBITION ROSES—ANALYSIS 1897—1904.

THERE are no statistics relating to exhibition Roses that create anything like the interest that attaches to the appearance every year of Mr. Mawley's Rose analysis, and which has recently been published in the columns of your contemporary the *Journal of Horticulture*. Issued by the esteemed secretary of the National Rose Society, they must entail many hours of hard work, and Rose lovers cannot be too grateful to him for undertaking such a task. It is only one more debt added to the many they already owe him, for the analysis solves, as nearly as possible, that all-important question for the old and young exhibitors alike, namely, which varieties to grow and how many of each he should select. I say as nearly as possible, because all statistics require careful consideration, and must be used with discretion and adapted to the individual requirements of each particular case; but, given these, I can conceive nothing more useful to exhibitors. If they are old hands at the game, with a collection of Roses that has served them well in the

past, they know the absolute necessity of keeping it up to date, and if they are just starting, here they have all the information they require for planting their Rose garden with varieties that should enable them to compete with the best.

It may be necessary for the benefit of those perusing this analysis for the first time to explain the methods which have been employed for many years past in compiling it. Since 1886 the name of every Rose in all the prize stands at the metropolitan exhibition of the National Rose Society has been taken down and the result afterwards tabulated. The average number of blooms thus dealt with annually has been about 1,800. In the complete table for the whole eighteen years can be found the number of times any variety was staged at all or any of those exhibitions. The present table deals with the last eight years only, as that number of years is sufficient to give the most trustworthy results, and in order to include therein the new Roses, and particularly those of most recent introduction, such as Frau Karl Druschki, Alice Lindsell, Florence Pemberton, &c., their place in the table is arrived at by taking the

number of times they have been exhibited in the 1904 show only. Combining, as the analysis does, the fruit of the last eight years, one arrives at results that may be expected from an average season; 1903, for example, was an extremely backward year for Roses, and the date of the metropolitan exhibition was unusually early, while this year the society was more fortunate, and the season was neither late nor early. The date just escaped being too late, with the result that the show for 1904 was a great success. Mr. Mawley, and none should know as well as he, claimed for it that it was the finest Rose show ever held. Thus the early and late seasons balance one another to a certain extent, but of course it is the midseason Rose that would probably be shown in a late as well as an early season that stands the best chance and comes out best in the long run. I have to thank both Mr. Mawley and the editor of the *Journal of Horticulture* for their courteous permission to make use of the article that appeared in that paper on the 3rd inst., and to those of your readers who are especially interested I would strongly recommend them to refer to the original notes.

HYBRID PERPETUALS AND HYBRID TEAS.

(TABLE I.)

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1904.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
*1	53.0	53	Mildred Grant, H.T.	1901	A. Dickson and Sons	Ivory-white, shaded pink
2	50.0	54	Bessie Brown, H.T.	1899	A. Dickson and Sons	Creamy white
3	43.9	45	Mrs. John Laing	1887	Bennett	Rosy pink
4	43.0	43	Fran Karl Druschki	1900	Lambert	Pure white
5	38.0	30	Caroline Testout, H.T.	1899	Pernet-Ducher	Light salmon-pink
6	37.9	42	Ulrich Bunner	1881	Levet	Cherry red
7	32.7	32	Kaiserin Augusta Victoria, H.T.	1891	Lambert and Reiter	Cream, shaded lemon
8	32.7	21	Marquise Litta, H.T.	1893	Pernet-Ducher	Carmine-rose, bright centre
9	32.7	21	Mrs. W. J. Grant, H.T.	1895	A. Dickson and Sons	Bright rosy pink
10	31.4	16	La France, H.T.	1867	Guillot	Silvery rose, shaded lilac
11	31.0	13	Mrs. R. G. Sharman Crawford	1894	A. Dickson and Sons	Clear rosy pink
12	30.7	27	A. K. Williams	1877	Schwartz	Bright carmine-red
*13	26.0	26	Alice Lindsell, H.T.	1902	A. Dickson and Sons	Creamy white, pink centre
14	25.1	18	Gustave Piganeau	1889	Pernet-Ducher	Shaded carmine
15	23.0	28	Her Majesty	1885	Bennett	Pale rose
16	22.7	21	Suzanne M. Rodocanachi	1883	Léveque	Glowing rose
17	22.1	3	Mme. Gabriel Luizet	1877	Liabaud	Light silvery pink
18	21.9	9	Captain Hayward	1893	Bennett	Scarlet-crimson
19	21.0	18	Horace Vernet	1866	Guillot	Scarlet-crimson, dark shaded
20	18.3	19	Helen Keller	1895	A. Dickson and Sons	Rosy cerise
*21	18.0	18	Lady Moyra Beauchere, H.T.	1901	A. Dickson and Sons	Madder rose, with silvery reflex
22	18.0	20	Ulster	1899	A. Dickson and Sons	Salmon-pink
23	17.9	11	White Lady, H.T.	1890	W. Paul and Son	Creamy white
24	17.2	16	Marie Baumann	1863	Baummann	Soft carmine-red
25	15.9	13	Prince Arthur	1875	B. R. Cant	Bright crimson
26	14.7	11	Dupuy Jamin	1868	Jamin	Bright cerise
27	14.7	0	Margaret Dickson	1891	A. Dickson and Sons	Ivory white
28	14.6	19	Alfred Colomb	1865	Lacharme	Bright carmine-red

* New varieties, whose positions are dependent on their records for the 1904 show only.

Mr. Mawley's most interesting comments on this table are as follows:

"If we turn to the table of Hybrid Perpetuals and Hybrid Teas it will be noticed that Mildred Grant for the first time heads the list, having displaced Bessie Brown, which had held that proud position unchallenged for the previous two years. The new queen of this section is a very large and most beautiful Rose. Its petals are of great substance and ivory white in colour with pink shading. Unfortunately, like Bessie Brown, it must be regarded as more particularly an exhibitor's Rose. Bessie Brown, on account of the pendent habit of its blooms, and Mildred Grant on account of its moderate growth. For ordinary cultivation such vigorous varieties as the next four Roses on the list—Mrs. John Laing, Frau Karl Druschki, Caroline Testout, and Ulrich Brunner—are to be recommended, as they grow and thrive with only moderate care, and possess almost every good quality such Roses should possess. They have all well-shaped flowers, vigorous constitutions, make good growth, and flower in the autumn as well as in the summer.

"Since last year Gustave Piganeau, another moderate grower, and Her Majesty, which bears fine show flowers, but is very subject to mildew, no longer appear among the leading twelve varieties, their places having been taken by Mildred Grant and Frau Karl Druschki, two new candidates for honours. If we take the first twenty-four varieties in the table we shall find they have also lost two old favourites, Prince Arthur and Alfred Colomb, their substitutes this year being two new kinds, Alice Lindsell and Lady Moyra Beauclerc. These and other changes of a similar kind clearly show that not only among the small free-flowering Roses, known as 'garden' Roses, are great improvements taking place, but that the same thing is going on among the large-flowered or 'exhibition' Roses, as they are called, and more rapidly, too, than at any previous period. This surely is a matter for much congratulation, and no doubt in a great measure accounts for the steadily increasing interest taken in Roses and Rose culture throughout the length and breadth of the land.

"Among the established varieties only Ulrich Brunner, Her Majesty, Alfred Colomb, Marchioness of Londonderry, Comte de Ruimbaud, and Fisher Holmes were unusually well represented at the last exhibition of the society. On the other hand, the following kinds have never before—and my reference tables go back eighteen years—been less numerously staged than on that occasion: Caroline Testout, Marquise Litta, Mrs. W. J. Grant, La France, Mrs. R. G. Sharman Crawford, Gustave Piganeau, Mme. Gabriel Luizet, Captain Hayward, and Margaret Dickson. Two causes, no doubt, combined to bring about the comparatively poor records of those varieties, viz., the later date at which the show was held this year, and the upward movement of the new Roses in the list.

"The continued onward and upward march of the Hybrid Teas is clearly indicated. Six years

ago there were only nine Hybrid Teas which found places in the table, last year there were eighteen, this year there were as many as twenty, seven of which appear among the leading twelve varieties. That the Hybrid Tea is still in its infancy is shown by the fact that there is not a single crimson (if we except Exquisite, nearly at the bottom of the table), maroon, yellow, or pure white Hybrid Tea on the list. These will all, no doubt, come in good time, but at present we have to be content that our five leading exhibition Roses should be either white or pink. Even if we take the first twelve varieties in the table, only three—Ulrich Brunner, Marquise Litta, and A. K. Williams—are any other colours.

"As many as fourteen new Roses—varieties sent out during the last five years—find places, and several very high places, in the list of Hybrid Perpetuals and Hybrid Teas. Of the five new sorts sent out in 1899, Bessie Brown takes the lead. It has fallen from the premier position since last year, but only to occupy the second place on the table. To show what a dependable exhibition Rose that fine creamy white variety is, it may be stated that at the last show it was rather more frequently staged than any other Hybrid Perpetual or Hybrid Tea. Ulster, distributed in the same year, has gained one place,

position in the analysis. Florence Pemberton, creamy white, tinted pink, sent out at the same time, secures a place at No. 48. Ben Cant, deep crimson, also a 1902 variety, just manages to come in at the end of the table. From an exhibitor's point of view, if from no other, the advances indicated by the above statements respecting the newer Roses must be regarded as very considerable.

"For instance, taking the leading new Rose of each year, we find the one sent out in 1899 at No. 2, that sent out in 1900 at No. 4, that sent out in 1901 at the head of the list, and that distributed in 1902 at No. 13. This, for five years, is an unequalled record, and it is a matter for further satisfaction that of the fourteen new Roses on the list, as many as twelve were raised in the British Isles, and no fewer than nine of them by a single firm, Messrs. A. Dickson and Sons, of Newtownards, Ireland. The only two new Roses of foreign introduction were sent out by Peter Lambert, of Trier, in Germany."

Mildred Grant's place at the head of the list comes rather as a surprise to me. One ought perhaps to point out that it is due to the fact that only its record for 1904 has been taken; as a matter of fact Bessie Brown was actually exhibited more times in 1904, but its record for the two other years being slightly lower tends to reduce its average. My own experience is that it is the more reliable Rose of the two, less liable to come split, and I think therefore it is still entitled to be called the leading exhibition Hybrid Tea. Next year will decide the point perhaps, but in any event it can only be a short-lived honour, for judging from what I saw at Messrs. Dickson's nurseries at Newtownards this summer there are many Roses coming along that will beat both of them. I do not, therefore, anticipate that either of them will hold the place of honour for so long a period as Mrs. John Laing, which headed this analysis for ten

THE POND AT TRELISSICK IN CORNWALL MARGINED WITH ARUM LILIES.

and now stands at No. 21. It is a very full, salmon-pink Rose of short upright growth; while Papa Lambert, pinkish rose in colour, rises from No. 65 to No. 61. On the other hand, Exquisite, crimson, and Mrs. Cocker, pale pink, have both fallen from No. 60 to No. 66. Frau Karl Druschki, a pure white Hybrid Perpetual, and one of the greatest acquisitions in that section for many years, whether regarded as an exhibitor's flower, or as a Rose for the decoration of the garden, is the most noteworthy of the varieties first introduced in 1900. Gladys Harkness, salmon-pink, of the same year, has risen from No. 66 to No. 38. Mildred Grant, ivory white, shaded pink, not only heads the list of 1901 Roses, but as before stated must now be regarded as the leading exhibition variety of the day. Lady Moyra Beauclerc, madder rose, on its first appearance in the list, takes up a very creditable position indeed at No. 21. Duchess of Portland, pale sulphur-yellow, also appears for the first time, and will be found at No. 34, while Mamie, rosy carmine, rises from No. 66 to No. 61. Alice Lindsell, creamy white, with pink centre, although only sent out in 1902, springs at once into a place at No. 13, and another year is certain to take a still more prominent

consecutive years. Increased competition tells its tale, even in the Rose lists. Grand flowers though Mildred Grant and Bessie Brown undoubtedly are, they will never be anything but exhibitor's flowers, and are not Roses for garden decoration such as the next four on the analysis, more especially perhaps Caroline Testout. I cut good flowers of this latter Rose only this week, mid-November.

Of Frau Karl Druschki one need only say that it has quite fulfilled its early promise of superseding all other white Hybrid Perpetuals, for a reference to the table will show that not a single flower of Margaret Dickson was exhibited in the winning boxes at the 1904 exhibition. It also promises to be quite one of the best of the autumn Roses. At a visit I made last month to one of our leading Rose nurseries I noticed that the rows of Frau Karl Druschki carried more flowers than any other Hybrid Perpetual, and nearly as many as Caroline Testout, Viscountess Folkestone, and La France.

Those two new Roses, Alice Lindsell and Lady Moyra Beauclerc—the latter an especial favourite of mine—have found their way into the first twenty-four, and next year will probably find them both in the first twelve, only its old average keeping

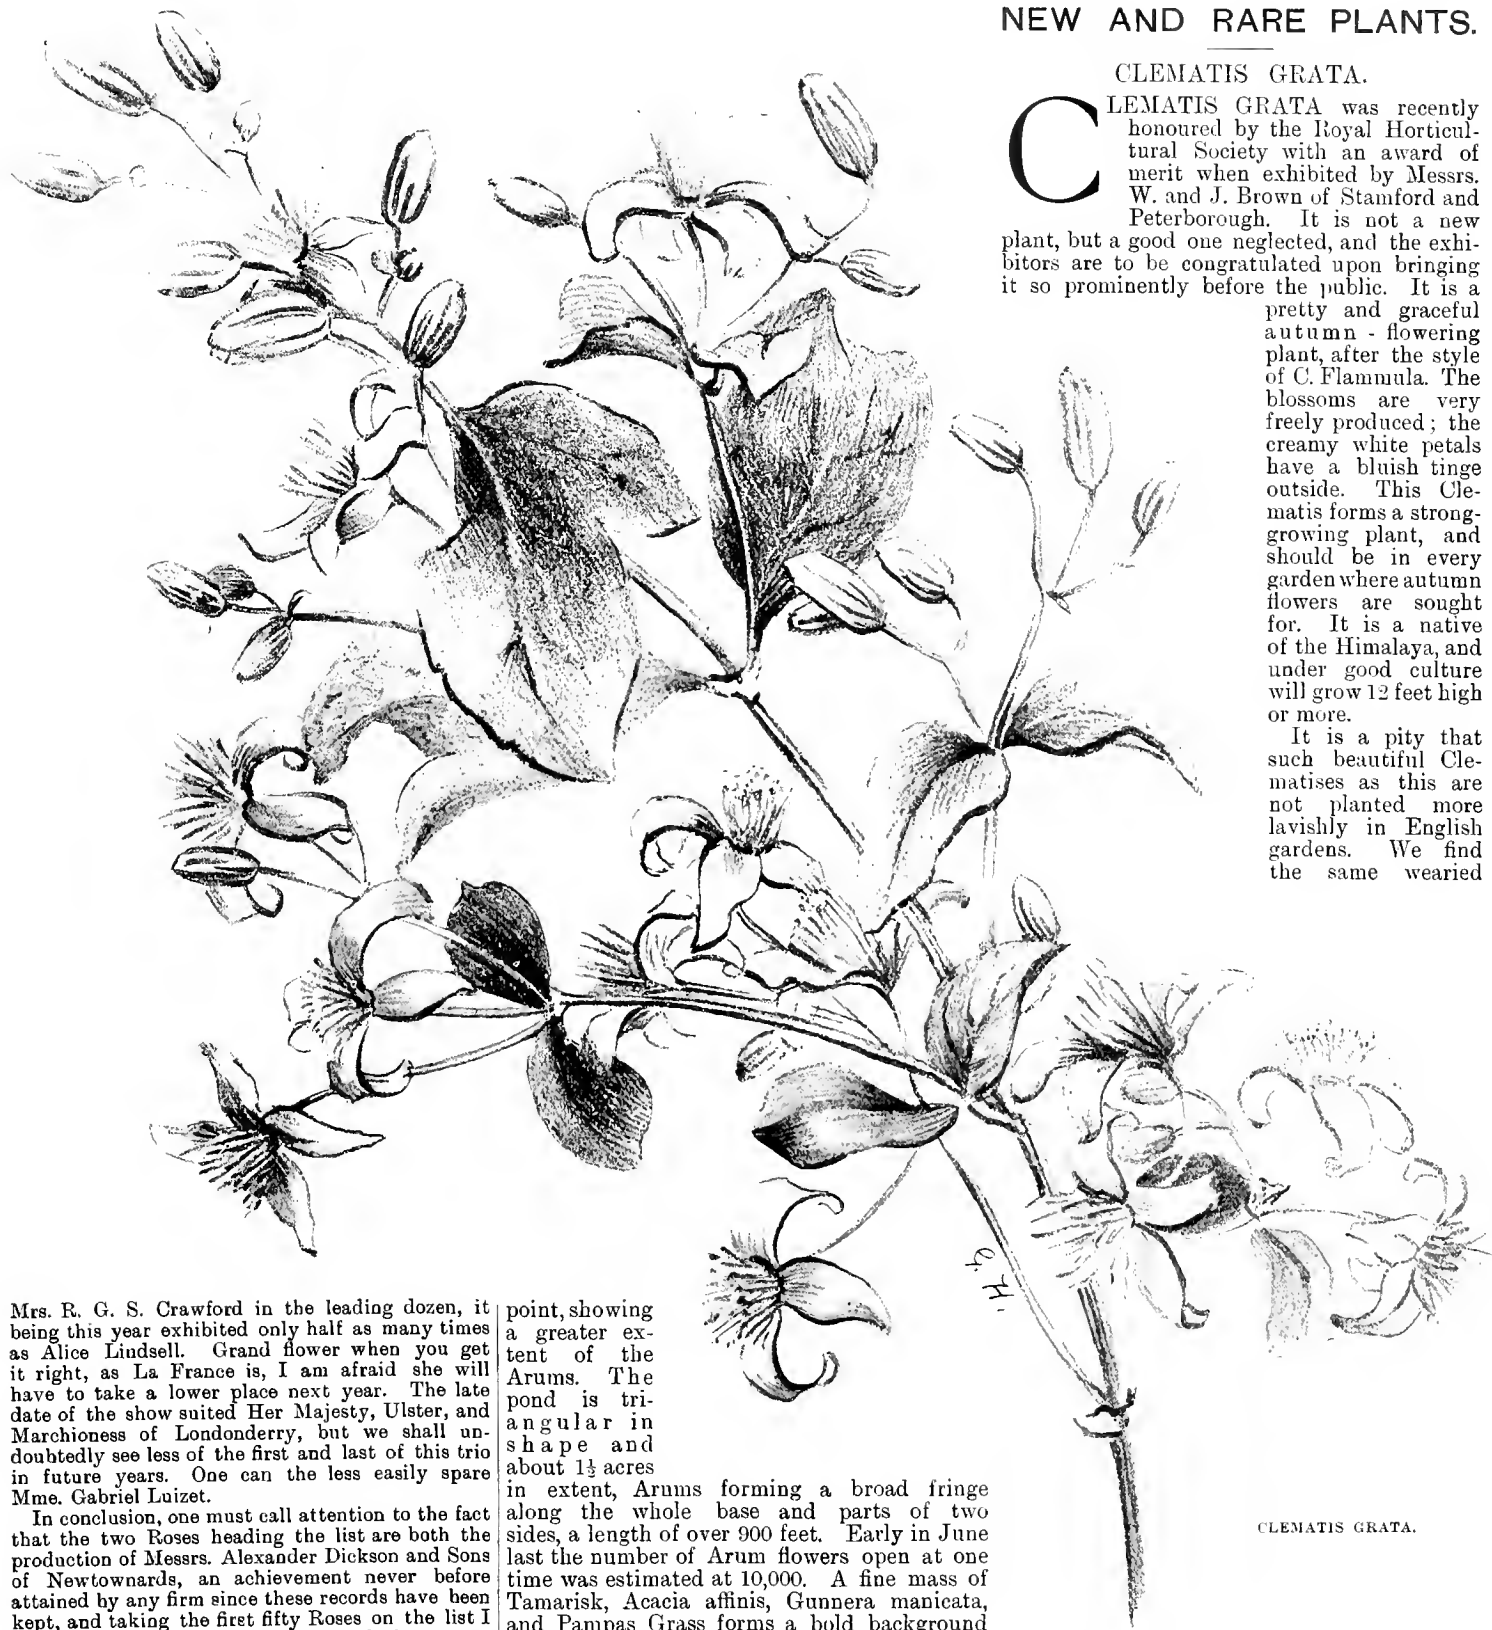

NEW AND RARE PLANTS.

CLEMATIS GRATA.

CLEMATIS GRATA was recently honoured by the Royal Horticultural Society with an award of merit when exhibited by Messrs. W. and J. Brown of Stamford and Peterborough. It is not a new plant, but a good one neglected, and the exhibitors are to be congratulated upon bringing it so prominently before the public. It is a

pretty and graceful autumn-flowering plant, after the style of *C. Flammula*. The blossoms are very freely produced; the creamy white petals have a bluish tinge outside. This *Clematis* forms a strong-growing plant, and should be in every garden where autumn flowers are sought for. It is a native of the Himalaya, and under good culture will grow 12 feet high or more.

It is a pity that such beautiful *Clematises* as this are not planted more lavishly in English gardens. We find the same wearied

CLEMATIS GRATA.

Mrs. R. G. S. Crawford in the leading dozen, it being this year exhibited only half as many times as Alice Lindsell. Grand flower when you get it right, as *La France* is, I am afraid she will have to take a lower place next year. The late date of the show suited Her Majesty, Ulster, and Marchioness of Londonderry, but we shall undoubtedly see less of the first and last of this trio in future years. One can the less easily spare Mme. Gabriel Luizet.

In conclusion, one must call attention to the fact that the two Roses heading the list are both the production of Messrs. Alexander Dickson and Sons of Newtownards, an achievement never before attained by any firm since these records have been kept, and taking the first fifty Roses on the list I find that no fewer than nineteen of them come from this firm. I hope to deal with the analysis of the Teas and garden Roses next week.

HERBERT E. MOLYNEUX.

THE LILY POND AT TRELISSICK IN CORNWALL.

MANY views of this pond have been published, but the present one was taken from a different

point, showing a greater extent of the Arums. The pond is triangular in shape and about $1\frac{1}{2}$ acres

in extent, Arums forming a broad fringe along the whole base and parts of two sides, a length of over 900 feet. Early in June last the number of Arum flowers open at one time was estimated at 10,000. A fine mass of Tamarisk, *Acacia affinis*, *Gunnera manicata*, and Pampas Grass forms a bold background to the Arums, and outside are hybrid Nymphaeas.

The only secret that I know of in connexion with Arums doing so well here is the fact that only a narrow embankment separates the fresh-water pond from the sea, so I attribute the credit to the influence of the Gulf Stream.

Trelissick, Truro.

WM. SANGWIN.

repetition of *Clematis Jackmani*, though this is charming enough, but *C. graveolens*, *C. grata*, and *C. paniculata*, to name only a few, have a grace and beauty that even *Jackmani* does not possess. With the greater facilities that now exist in many gardens in the shape of a pergola one would expect to find the rarer climbers more freely represented.

ROUND ABOUT A GARDEN.

A BUSY TIME FOR SPARROWS.

THIS is almost the busiest time for birds in the garden. It is the turn of their year, when they have all sorts of arrangements to make. The sparrows have for weeks been furnishing their winter sleeping places, and feathers from the fowl-yard are at a premium, while each chirper on the roof keeps one eye upon the toilette of the ducks, in case they may discard some of those fluffy underfeathers which upholster a nest so nicely. So the sparrows have plenty to talk about when they assemble in the shrubberies and all shout at once in the morning, though there is now very little of that vulgar chasing about in the bushes which is their method of love-making. This the sparrow postpones until early in the year, when the grey margins of his winter feathers will have worn off, and he will be able to hop around in spatecocked attitudes before the lady of his choice, alternately exhibiting to her the contrasting greys and browns of his plumage behind and the jet-black bib that he will wear in front. At present his black bib is covered over with serviceable and seasonable grey, and he forages for feathers on his own account.

THE HEDGE-SPARROW AT HIS NOISIEST.

The hedge-sparrow, ordinarily the quietest and least obtrusive of birds, is at his noisiest now. Resuming song in autumn several weeks later than the robin, he seems filled with the idea that he must make up for lost time, and often sings his tweedling little song a score of times in quick succession, and almost without taking breath. Then he descends into the depths of the shubbery, and you hear his progress through it by the thin piping notes in which he protests against the presence of a hated rival on the premises. For this is the hedge-sparrow's mating time, and he is the most uxorious of little birds. A little later you will seldom see him or his wife when they are not pattering along the path together with their little ruddy feet, she all demurely brown, and he, a foot or so in advance, distinguished by the bluish-grey colour of his head. But now all is turmoil in the hedge-sparrow's life. Even if he has secured a mate, the event is so recent that rivals are still hanging around; and the great question of hunting grounds for the winter has not been properly decided. So there is a world of excitement in the hedge-sparrow's thin piping as he slips hurriedly through the shrubbery, nervously flicking his wings at every step.

BLACKBIRDS' QUARRELS.

The blackbirds seem to have got no further than the hedge-sparrows in the settlement of their winter boundaries, for great chases take place now and then when two or more yellow-billed warriors find themselves using the same lawn. But, unlike the hedge-sparrow, the blackbird does not yet think seriously of matrimony, and, when he does, it will be the hen birds that must do the quarrelling for mates, while each cock bird will watch the varying fortunes of the struggle for his affections as an interested spectator. In the spring, however, when another general rearrangement of bird population takes place, it will once more be the turn of the males to contend for nesting-sites. Thus, the rule of blackbirds' social ethics appears to be that the males must fight for the homes and the females for the husbands who own the homes. This, no doubt, has tended to the beautification of the male blackbird, for, other things being equal, it is

manifest that the handsomest husband would excite the keenest competition, and so get the best wives.

ROBIN AND TIT POLITICS.

Robin politics differ again, for they not only begin their arguments about hunting grounds for the winter earlier than the others, but also effect so complete a revolution in domestic matters that the males and the females fight separately, each on his or her own account, and often, as it would seem, against each other. Not until signs of spring are appearing on every hand will the robins begin to think of each other with any tender feelings. All through the winter months husband and wife meet less as strangers than as enemies. This is, no doubt, the reason why female robins sing almost as well, and as frequently, as the males, since they have equal need of a war-cry. Except that they fight less for their holdings, wrens seem to be like robins in the separation of the sexes in winter; and most of the tits also live in single independence then, strictly arranging their order of precedence at the bird-table by their fighting weight. Very pretty it is, as spring approaches, to see the change of manner which comes over them, and with what dignity each half-ounce warrior will induct his bride to the table and permit her to feed by his side.

THE FASHIONS OF FINCHES.

From watching the chaffinches in the garden one is apt to get confused ideas at first, because while one fine cock chaffinch will permit no other to approach his corner of the garden without battle, in another part you will often find a whole flock of chaffinches quietly feeding together. The difference is, of course, that the handsome autocrat is an old married bird with a home and wife of his own to defend, while the others are young birds of the year, which have wandered together from nobody knows where, but simply drift where food happens to be plentiful. Like human young people, too, before they are old enough to fall in love, these young chaffinches prefer to gather in crowds of their own sex. Among British finches this division of the community into old and young, and the further subdivision of the young into male and female, seem peculiar to the chaffinch, goldfinches apparently preferring to remain in family parties, and greenfinches assembling in promiscuous flocks for the winter, while bullfinches seem to break up into separate couples in autumn. These different arrangements of their lives make the birds always an interesting study in the garden at this season, when the leafless trees and bushes permit you to see so much more of their conduct, and when they have so many affairs to settle.

E. K. R.

GARDENING OF THE WEEK.

FLOWER GARDEN.

BEDDING PLANTS.

BEDDING plants are now in their winter quarters. Pelargoniums should be kept on the dry side, and as cool as possible. All decaying foliage should be frequently removed. Fuchsias which have lost their leaves may be stored in any out-of-the-way corner of the shed, and, of course, will not require to be watered for some time. Such plants as Heliotrope, Irisine, &c., which must be wintered in heat, should be placed as near the glass as possible, so as to keep them dwarf and sturdy. Whenever possible the lights should be entirely removed from the Calceolaria pits, or the mild weather will induce them to

start into growth, which would be soft and not fit to withstand any cold weather. Covering material must be kept at hand in readiness or a sudden frost may do a lot of damage to bedding plants in frames and unheated pits.

VERONICAS, HYDRANGEAS, &c.

Cuttings of these flowering shrubs, if firmly inserted in boxes of suitable soil and placed in a cold pit, will root during the winter, and a few small plants from the borders, if potted up and wintered in the same manner, will be valuable should a severe winter set in. Cuttings of Pentstemons may also be inserted; these will root more readily if placed in pots. Seedling Hollyhocks should be potted up, well draining the pots, and using a light, rich soil. The plants may be wintered in a cool greenhouse or a frame, admitting air freely whenever possible. An occasional dusting with flowers of sulphur usually keeps them free from the fungus.

PLANTING UNDER LARGE TREES.

The bare places under many large trees are frequently a source of worry to the gardener; grass fails to grow, and even the special mixture of grasses recommended for such places soon become weedy and quickly die out. Under many conifers where the shade is dense even that last resource, Ivy, frequently fails to cover the ground. In such cases the best method is to top-dress the tree well with road soil if it can be procured, hoping to induce it to grow freely, and that as the branches elongate they will ultimately hide the bare places. With deciduous trees and evergreens, when a fair amount of light penetrates, much may be accomplished. The soil around the tree should be well broken up. If the soil is at all dry it should receive a copious watering. Then add a quantity of as good soil as can be afforded. After planting well water, and if the time can be spared to syringe the shrubs on dry days they will become established all the more quickly.

SORTS TO PLANT.

This will be a matter largely of district, density of shade, and personal taste; but evergreens will, of course, largely predominate, and unless the space to be planted is large the kinds selected should be as dwarf-growing as possible. The following are a few of the shrubs suitable for the purpose, and will serve to suggest others: Hypericum calycinum, Gaultheria Shallon, G. procumbens, Andromeda Catesbaei, the dwarf and double Furzes, the Butcher's Broom and Ruscus Hypophyllum, R. H. var. Hypoglossum, Vincas, &c. The Sweet Briar and several species of Rosa which become well furnished with hips will supply colour during the winter. If given a peaty soil the Hart's-tongue Fern and some Aspidiums would thrive.

Many bulbous plants might be introduced, such as the hardy Cyclamens, Lily of the Valley, Schizostylis coccinea, Hellebores, Colchicums, the sweet-smelling Coltsfoot, as well as many Crocuses and Narcissi.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

FRUIT GARDEN.

PRUNING.

Most of the leaves have now fallen, so a start should be made with this work and advantage taken of the mild weather. Pears on walls may be commenced with as soon as Cherries are finished. On old trees which are too crowded with fruit-spurs a few of the worst of the latter should be removed annually, as new shoots generally form freely at the base. Cut back the other young shoots to two or three buds, according to the variety, care being taken in pruning such varieties as Marie Louise, which form fruit-buds at the end of this season's shoots. The shortest of these should be allowed to remain, when they can be cut back at next year's pruning. When pruning is finished nailing and tying should follow; remove the oldest shreds and burn them, at the same time heating the nails to clear them of insect eggs. Use tarred twine for the main branches and clean shreds not too broad for the smaller ones, care being taken not to tie them tightly.

Young horizontally-trained Pear trees which have not filled the required space should be cut back according to strength and the further extension required. Young trees which have been recently planted should only be tied loosely until the soil has thoroughly settled down. The pruning of Pears, Apples, and Plums in the open quarters should next receive attention. Where these trees are given proper attention by summer pinching very little winter pruning is necessary. Thin out the oldest or worst-placed branches on old trees, and thin out the remaining spurs if set too thickly. Carefully thin and regulate the shoots of young trees, and secure them to stakes to bring them to the required position. American blight should be carefully watched, and severe measures taken to keep it in check. Methylated spirit applied with a stiff brush is as good as anything; rub it well into the affected parts.

BUSH FRUITS.

The pruning of these should now be done if possible. In many cases, however, birds are so troublesome that it is best deferred until the spring. Varieties of Gooseberries wanted for dessert should be thinned the most, spurting in the side shoots to two or three buds. Red and White Currants require the side shoots spurred in the same way, and the leading shoots to five or six buds. Remove only the old wood from Black Currants, leaving the young and vigorous shoots, which produce the finest fruit.

GENERAL NOTES.

Now is a good time to give liquid manure to trees which have carried heavy crops of fruit and have not made much growth. Loosen the surface soil, add the same quantity of water as manure, and apply at intervals of two or three weeks or whenever it is available. This will have an invigorating effect on old and exhausted trees either in the orchard or garden.

Impney Gardens, Droitwich.

F. JORDAN.

INDOOR GARDEN.

TEA ROSES IN POTS.

UNDOUBTEDLY from plants growing in pots can be cut the greatest number of flowers for the earliest supply. To have them in flower early in the new year the plants should now be ready for taking under protection. For a fortnight they are better for being in a house that is kept closed, no fire-heat being necessary unless severe frost sets in, and then only sufficient to maintain a temperature of about 40°. Syringing may be indulged in, but very lightly, and only during bright weather. Water during this time should be very sparingly given. The hard growth of the plants will by that time have softened, and consequently be ready, immediately they are given a little warmth, for putting forth a robust and free growth that will flower abundantly. The supply of water to the roots must be increased as growth advances, as at this time root action also increases and requires support.

PROPAGATING CHRYSANTHEMUMS.

Preparation for putting in the cuttings with despatch is a work now to be reckoned with, and the longer the operation is delayed the more likely are the cuttings to become drawn and weak. A good position in which to root them is a temporary frame in a dry cold house that is frost-proof. For the purpose obtain strong short-jointed root or sucker cuttings, and insert these singly in 2½-inch pots, or three around the sides of 3-inch pots. Drain the pots well, and fill them with a mixture of finely-sifted leaf-soil, a very small amount of fine loam, with plenty of sand, and in this insert the cuttings, being careful to make them very firm at the base. A thin shade during bright sunshine may occasionally be necessary, but in no case should the light be unnecessarily subdued. Should there be any drip from condensed moisture on the glass admit a little air to the frame, or wipe the inside of the glass with a dry cloth every morning.

BEGONIA GLOIRE DE LORRAINE.

The temperature of the house in which the earliest plants that are in flower are situated should not rise above 50°, and a buoyant atmosphere

should be maintained by the judicious admission of air. Those plants that are still growing and will flower later require a little moisture, created by sprinkling water about the paths and stages, and a temperature 5° higher. Generally the plants are grown in very small pots, and to keep them in robust health apply, with consideration, guano and soot-water, as well as a dose or two of Clay's Fertilizer.

J. P. LEADBETTER.

Tranby Croft Gardens, Hull.

ORCHIDS.

FURNISHING ORCHID HOUSES.

The present time, when there are not quite such urgent calls upon one's time, is a suitable one for carrying out improvements in many houses, as, for instance, the introduction of a little rockwork under the stages; it should be made to face the path, and be kept so low that the circulation of heat and air is not interfered with in any way. In planting select plants that are not liable to insect pests. We find the varieties of Begonia Rex very suitable and pleasing when mixed with Ferns, &c. Few things are more objectionable than bare walls in glass houses, and I think this is even more pronounced in Orchid houses. With little trouble they can be converted into objects of beauty. In the cooler houses Ficus repens will prove a suitable covering, and common Orchids may be planted in terra-cotta wall pockets and fastened on; in the warmer houses the scandent Epidendrums may be used to advantage. It is also unwise to have the Orchids too near the path. If they are kept back far enough to give room for a single row of small decorative plants, these will form a protection to the choicer plants and give great relief to the general appearance of the house. To get the best results from one's houses these items require attention. I am sure that planting and covering the walls is very helpful in promoting a suitable atmosphere in addition to enhancing in no small degree the attractiveness of the houses.

ZYGOPETALUM MACKAYII.

For the well-being of this fine winter-flowering species it is necessary to allow the plants to become dry before water is given. The black spot so often seen on this Orchid is often caused by watering too freely at this season. The spikes are now well advanced. The new pseudo-bulb is not developed till the flowering season is over, so one would naturally conclude that much water was necessary, but when they are potted in such a compost as I advised in my notes of February 13, and grown in the cool intermediate house, very little water will be needed. When they are watered it should be done thoroughly, so that the whole of the compost is moistened, and if they were dry previous to being watered they will quickly dry again.

LELIA ANCEPS AND ITS VARIETIES.

The flower-spikes are now fast developing, and they should be secured to neat stakes. Some will now be emitting roots. They should be given more water than others that so far have not reached that stage. Light being such an important factor towards the proper development of the flowers, everything that can possibly be done towards that end will be well repaid.

NURSERY GARDENS.

CHRYSANTHEMUMS AT KESTON AND LEWISHAM.

MR. H. J. JONES'S NURSERIES.

RYE CROFT NURSERY, since it was taken over by Mr. H. J. Jones in 1890, has been a home of the Chrysanthemum. In the earlier days atmospheric conditions at Lewisham were much better than they are to-day, and for this reason the flowers of new and choice sorts were developed to a high state of perfection. Times and conditions have changed, however, and with less favourable atmospheric conditions that

prevail to-day it is impossible to develop flowers of the high quality that growers far removed from the London smoke can do with comparative ease. For this reason Mr. Jones has wisely partly moved to the new quarters at Keston. For the moment we will confine our attention to the collection at Lewisham, where several large houses are filled with thousands of plants embracing all types, and where, all things considered, the plants are doing extremely well. The collection here is a very representative one, and in consequence Japanese, singles, incurved, reflexed, Anemones, and Pompons are charmingly displayed. The two large houses, each 110 feet long by about 25 feet wide, lend themselves for this purpose. On the occasion of our visit the Japanese varieties were in superb form, novelties abounding, contrasting pleasingly with some of the older ones. One could hardly credit that the plants were grown within six miles of Charing Cross.

Single-flowered varieties, in both large and small-flowered types, were extremely dainty and interesting, and convinced one of their value for floral decorations. Generally speaking, the plants were profusely flowered, and their forms and colours pleasingly varied. Striking examples of these charming flowers were Paris Daisy, a pure white flower on a plant with a perfect habit; Althea, a large rosy magenta flower, shaded cerise, and yellow disc; Mrs. C. Symms, an enlarged form of the popular Miss Mary Anderson, colour bluish white; Princess, a beautiful pure white, petals slightly incurving, colour soft bluish, grand clusters when undisbudded; Mrs. E. Roberts, charming bluish rose of large size with white zone round yellow disc; bronze sport from Edith Pagram, a grand acquisition, colour reddish bronze; Miss Jessie Dean, a Rye-croft seedling, soft rose with broad white zone round disc, very free and pretty; White Gem, a miniature-flowered white sort, with several rows of petals, excellent for decorative uses when cut in undisbudded sprays; Mrs. Chas. H. Curtis, a glorious crimson of good form, in flower from September till November; Miss D. Bainbridge, an interesting free-flowering large deep rose; Mrs. R. N. Parkinson, a charming bright yellow flower of medium size, beautiful when cut in sprays; and Miss H. Hampson, a creamy white of large size and good form, besides quite a large number of standard sorts. This section will most assuredly become very popular. An immense number of Japanese and other novelties are grown on single stems in 6-inch and slightly larger pots. The flowers developed on many of them were almost phenomenal in size and other high qualities. A magnificent group of the lovely orange yellow Japanese Duchess of Sutherland was the admiration of all. This variety has done exceedingly well almost everywhere this season.

Early flowering varieties are grown in a separate nursery some way from Rye-croft. From August until the end of October, and even later, there has been a blaze of colour, and the most gratifying fact in this connexion is that the Rye-croft seedlings have eclipsed all others. They are noted for their striking colours. Specially good Japanese sorts were: Fire Dragon, vivid crimson; Howard H. Crane, chestnut; Freedom, rosy purple; R. Pemberton, amaranth; Pride of Keston, reddish rose; Pride of Hayes, soft rose; Nina Blick, crimson bronze; Mrs. W. A. Hobbs, rosy carmine; and a very dwarf plant aptly named Dwarf Perfection, rich golden bronze. One advantage the Lewisham stock of Chrysanthemums possesses is its freedom from the much-dreaded leaf rust. The smoky atmosphere acts as a preventive. Rested stock is a great feature at Rye-croft Nursery. Stock plants in pots are plunged in the open during summer and early autumn, and before the cold or uncertain weather is experienced these are lifted and planted under glass. Plants treated in this way give plenty of good cuttings.

The new Leafy Grove Nursery at Keston, Kent, is about two miles from Hayes Station (S.E.R.). It has a beautiful southern aspect, and is protected from north and east. Here 3,500 plants are grown especially for exhibition blooms, and this year they are superb. Three very large, handsome, and commodious glass structures, ideal for

the purpose, are utilised in which to flower the plants, and on the day of our visit the flowers were in the pink of condition. Novelties abounded, and there were also a number of promising seedlings. Of the more popular Japanese sorts, Mr. F. S. Vallis, the grand canary yellow flower, was in superb form, as were also the striking flowers of Henry Perkins, the golden yellow and crimson Japanese of English origin; in fact, continental novelties were almost absent, the quality of the newer English-raised seedlings being better in many respects. There were magnificent blooms of Bessie Godfrey, and the glorious butter-yellow ones of Mrs. Greenfield were very effective. A Japanese flower of a type resembling Lord Ludlow is Mrs. Wheeler Bennett, a promising variety. Mildred Ware, sent out by Mr. Jones in 1903, has been a great success here as elsewhere, and the lovely terra-cotta crimson, Phillipe du Cross, was much admired. Mrs. J. Hadaway, the pale fawn sport from Mildred Ware, is even better than the parent plant, and several fine blooms were there. The rich lake-coloured blooms of Willie Ballimore are of immense size, and keep well. Another large flower is Charles Hobbs, colour rich blood-red, with broad leathery petals. Mrs. Bischoffsheim, the crimson and golden yellow sport from Miss Lily Mountford, is a striking flower; and the deep pink, Mrs. G. D. Judge, is a Japanese variety that should be in all collections. New varieties Mr. Jones promises to distribute next spring are Mrs. Boosey, a deep rose-pink flower, with silvery white reverse, having broad petals, curling and incurving; Lady Lennard, a large, full, neatly incurved Japanese of good form, colour terra-cotta bronze, a plant easily grown; Mrs. W. Elliot, a creamy white Japanese seedling of great promise, the petals prettily twisted and curling; and Mrs. E. Crossley, a very large flower, quite 8 inches deep and 8 inches broad, the petals broad, and building a full exhibition bloom, pale straw yellow. Other popular sorts that attracted our attention amid the immense number of well-grown flowers were Mrs. F. W. Vallis, W. Duckham, a pretty silvery rose incurved Japanese; Duke of Devonshire, canary yellow, shaded apricot; Mrs. J. Dunn, a superb white; Maud du Cros, pale yellow, tinted green; Miss A. Brown, yellowish buff, shaded with chocolate; Edith A. Fuller, the bronzy red sport from General Hutton; Valerie Greenham, a pleasing pink Japanese bloom of drooping form; President Viger, a novel flower; Mrs. C. Beckett, the new white; Miss Cicely, a glorious rich yellow; and the striking Josephine Ronset, a beautiful rosy amaranth, and a colour badly needed. To Mr. R. C. Pulling, the grower, much credit is due for the excellence of the display, and he is ably assisted by Mr. R. Kenyon, an old and well-known grower and prize-winner.

A GENERAL CALENDAR.

FORCING VEGETABLES.

HOWEVER plentiful outdoor vegetables may be during the winter season there is always a demand for a choicer variety, and if given suitable convenience and material to work upon there is no great difficulty in meeting it.

French Beans.—This is without doubt the most difficult vegetable to obtain in quantity for the next three months, for without plenty of light growth is weak, and many of the flowers which form fail to set, especially when there is an absence of sun and foggy weather prevails for days together. The most suitable house must be selected, such as a well-heated Melon house, where the plants can be kept close to the glass and a temperature of not less than 70° be maintained. Pot culture is the method chiefly resorted to in private gardens, and I prefer pots about 7 inches in diameter, as they take up less room, and better results follow in having these well filled with roots than are obtained by using larger ones only partially filled. Those varieties only of a naturally dwarf and free-bearing habit should be selected, such as Osborn's Forcing, Syon House, and Fulmer's Early Forcing.

Carrots.—Only a very gentle heat is required to force these, and young Carrots are highly appreciated in the winter. A steady warmth produced from a body of leaves and well-made frame with a few mats for covering at night are all that is required. Where these are available they could hardly be put to a better use. If a steady bottom-heat is to be maintained from now until spring make up a bed, from 3 feet to 4 feet high, on which to place the frame. The bed should be made sufficiently wide so that more leaves can be packed round the sides of the frame, and if it is thought that the leaves will not generate sufficient heat in themselves, a little fresh stable litter mixed with them will promote fermentation. Having prepared the bed and placed the frame in position, about 9 inches of rich light soil should be put in the bottom and the frame closed for a few days. When the compost is warmed through the seed should be sown thinly and evenly over the surface, and covered with a slight sprinkling of sandy soil. A light watering through a fine rose will assist germination. Keep the frame close until the seedlings push through. Air should then be given, varying it according to outside conditions of the atmosphere. I find that Parisian or French Forcing Horn varieties are the best to sow at this season.

PELLÆA FLEXUOSA (A RARE MEXICAN FERN).

Radishes.—These are always appreciated when produced during winter, and when grown on a gentle hot-bed the flavour is milder and the roots more tempting than those grown in the open during summer. The same conditions should be followed as recommended for Carrots, only a less depth of soil is required, and this, if possible, should be brought to within 6 inches of the glass. Wood's Frame is a most reliable variety for present sowing.

Roses for Forcing.—Now is a good time to procure established Roses in pots. Such plants may be pruned and forced immediately, their pots being already full of roots. A top-dressing may be advisable, mixing with the loam a little guano; Roses greatly appreciate this manure at all times.

Rose Crimson Rambler.—If this and other Roses are required to bloom about Easter some plants in pots should be procured now, or ground plants potted up would do well. These should be kept cool through the winter, but may be gently forced after new roots have been made.

Forcing Snowdrops.—It is almost impossible to force these very early, but they may be brought into bloom slightly in advance of those outdoors. If

they are wanted very early the best way is to pot or box them early in autumn, keep them in a cool position, and cover with ashes. When growth is advanced remove them to a cool pit, and about Christmas they may be brought into a moist structure, where the temperature does not exceed 45°. Give them a light position with plenty of air; if given too much heat the blooms will not open, all going blind. Excellent Snowdrops may be grown in pots and boxes if brought on slowly in frames, kept close and free from frost.

TROPEOLUMS FROM CUTTINGS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The practice of propagating *Tropeolums* by cuttings is not so unusual as one might think from a perusal of the article on page 309, where instructions are given for carrying this out. From time immemorial cuttings have been used for the increase of the different forms of the lobbianum section, of which large quantities are grown every year. Some thirty to forty years ago, before zonal *Pelargoniums* were so much employed for winter blooming as they are nowadays, *Tropeolums* of the lobbianum class were largely grown for the purpose, and they were invariably propagated by cuttings, one variety in particular, known as Mrs. Treadwell, being cultivated in large numbers. At that time it was to be found trained up rafters and in similar positions in the different market nurseries, so that bunches of *Tropeolum* flowers formed a prominent feature in Covent Garden Market throughout the winter months. The most popular colour was a rich deep scarlet. T.

PELLÆA FLEXUOSA (A MEXICAN FERN).

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I am sending you a frond and a photograph of the Climbing Fern (*Pellaea flexuosa*), a plant of which I found in 1891 in a dell near the town of Orizaba, in Central Mexico. It was a poor little plant, and its fronds were climbing up a young Thorn tree. It was the only specimen of this Fern that I found, though I brought home roots of various other species of interest. On my return home it was placed in the greenhouse, where it soon grew into a fine plant. It might, perhaps, do better in a stove, as about Orizaba the scarlet Hibiscus forms glorious hedges round the Coffee plantations, the Banana trees flourish by the river, and various beautiful Orchids grow in the surrounding forests. I sent a frond of my Fern to the Curator of Kew Gardens, and he was kind enough to name it for me. He said they had never had a plant of it at Kew, and, if I remember rightly, he said mine was the first specimen that had been introduced into England. It can be very easily increased by division, but is difficult to raise from seed, though it occasionally seeds itself among other pot plants. I have a nice stock of young plants now, and was glad, a few years ago, to be able to send a good specimen to Kew. The plant, of which I send you the photograph, is growing in a 10-inch pot, and measures about 6 feet from the rim.

EDITH A. BAILEY.

Rowden Abbey, Bromyard.

P.S.—Curiously enough, another year I brought home from the Yosemite Valley two plants of another *Pellaea*, of which I now forget the name, which was not in the collection at Kew. Unfortunately, I did not succeed in propagating it and lost both plants.

FRAGRANT HARDY CHRYSANTHEMUMS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Having read your note in THE GARDEN of the 12th inst. on hardy Chrysanthemums, I think

it would be very interesting to have a good collection of sorts that possess a distinct fragrance. Here are the names of a few: Progne, amaranth, Violet scented; Mrs. E. W. Clark, deep claret, sweet scented; Kate Williams, rich golden yellow, sweet scented; Mrs. Lungtry, rose blush, very sweet; and May Blossom, crimson-maroon, which is described as having a strong scent of May Blossom. If any readers know of more than these five varieties I should be pleased to have the names.

S. BARTRAM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Anyone who wishes for sweet-scented Chrysanthemums should grow the white, violet-scented Pompon Scur Melaine, which flowers in October equally well outside or under glass. Another delightful thing is Miss Annie Holden, a fawn-coloured single, whose delicious perfume is made up of honey combined with the aromatic smell of the Chrysanthemum. This also does very well out of doors.

Cumberland.

CLARA MYERS.

EREMURUS ROBUSTUS IN SCOTLAND.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I herewith enclose a photograph of Eremurus robustus, which you will perhaps think worthy of a place in your valuable paper. [Unfortunately, not suitable for reproduction.—Ed.] An illustration of the same plant appeared in THE GARDEN for August 30, 1902. Since then it has steadily got stronger, and this autumn we have divided it and have got thirteen strong crowns. These we have replanted. The plant is growing in a herbaceous border, with a south-west exposure, and beyond receiving careful attention in the matter of protecting the young shoots from frost when they appear in spring, it is treated in all respects in the same way as the other occupants of the border. Although the shoots this year were over 10 feet high, they required no supporting. The photograph was taken by Mr. McGregor, Kelso.

WILLIAM WOOD.

The Gardens, Newton Don, Kelso.

LILIUM LONGIFLORUM HARRISII
OUT OF DOORS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Would the enclosed photograph be of any use for publication in THE GARDEN? It shows Liliun longiflorum Harrisii planted in a south border. They remained in flower at least three weeks. Similar groups in other situations and in

A BED OF LILIUM LONGIFLORUM HARRISII.

different soil did equally well. They were grown in Colonel Hanford's garden, Flood Hall.

ANNIE HANFORD-FLOOD.

Thurston Cottage, Bury St. Edmunds.

APPLE BEAUTY OF BATH.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I, too, have a good word to say for this early dessert variety. Three years ago I grafted several standard trees of Ecklinville Seedling with

this variety. The grafts grew amazingly, and now they are huge heads, and gave a good crop of fair-sized, highly coloured fruit, which were disposed of quite readily. I intend to add this more freely to the collection here, as I can see it is infinitely superior to many so-called good market Apples.

Swanmore.

E. M.

PHYGELIUS CAPENSIS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—A peculiar circumstance arose a few weeks ago in regard to the staging of this Figwort as a herbaceous plant. The judges passed it as such, but an exhibitor protested that it was not eligible as a herbaceous plant on account of its not dying down annually. In a mild winter it does not die down to the ground line, but remains quite woody, and produces its flowers from these parts as well as from the current year's growth from the base. Nicholson describes it as a South African shrub, and recognising this authority one is led to the conclusion that the protest alluded to had good and reasonable grounds, in spite of his objection being overruled by the judges. For September and October it is a desirable plant, as with liberal treatment in a sunny spot I find it thrives amazingly. I found it growing here twenty-six years since, and here it is in spite of the hardest frost we have had, and without any protection; thus there cannot be any doubt about its hardiness.

South Hants.

E. MOLYNEUX.

FREESIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In a recent issue of THE GARDEN a writer stated that he had just withdrawn his bulbs from the plunging material. When I first began growing Freesias I thought it best to plunge the pots until the young growths were well above the soil, but I have since found this to be absolutely unnecessary. The less one fusses about Freesias the more likely they are to do, and I now treat them in the same way that the Guernsey growers do. I put them in the open in the full sun, and allow them to remain there until the latter end of September. Sometimes, if I happen to have frame room, I keep them out until November, just protecting from sharp frosts. In this way they start under natural conditions. I usually pot all my bulbs early in August, as I have not found that later potting gives succession. I believe that, as in the case of Hyacinths, it is better to pot all the bulbs early, and forward or retard in other ways. Some complain that their stock deteriorates, but I am strongly of opinion that much of this deterioration is due to comparative neglect after blooming. Bulbous-rooted flowers more than other things are apt to be overlooked after blooming.

J. CORNHILL.

LILIUM TESTACEUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In reference to the note on page 332 of THE GARDEN for the 12th inst. about Liliun testaceum, in "Hansmann, Flora von Tyrol," Vol. II., page 874, appears the following note about the distribution of Liliun candidum: "In gardens, more especially in those of country folk in the mountains (*sic*), Bozen. On a slope of the Streiberg as a garden fugitive." Now, does not this point towards the probability of a similar occurrence in the case of L. testaceum in Switzerland, as mentioned by your correspondent? For, what is more likely to happen in the mountains, where cereals are not grown and litter for the stable is consequently always a scarce commodity, and where notoriously every available scrap is being carefully collected for that purpose, than that in this manner the refuse of a peasant's garden, seeds and all, should find its way to the refuse heap, and thence as manure to the grassy slopes, where any stray Lily seeds would find congenial conditions for germination? I have not a "Flora of Switzerland" by me, but surely, were L. testaceum indigenous there, such a conspicuous flower could not possibly have escaped the notice of botanists. L. testaceum

has, however, a very decided oriental aspect which makes the theory of its being a hybrid more acceptable. In the Tyrol only L. bulbiferum and L. Martagon are indigenous.

Planegg, Bavaria.

E. HEINRICH.

PEAR CONFERENCE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—This Pear takes its name from the Pear conference held at Chiswick at that time. It has

PEAR CONFERENCE ON A WALL.

received a first-class certificate from the Royal Horticultural Society. It grows and bears equally well on the free, Pear, or Quince stock. It has a good constitution, and is a most profitable variety for market. The unripe fruit is most excellent when stewed, and this is a very good way to utilise those fruits that fall or are damaged. The tree illustrated was planted in my garden at Fontley four years ago, against a wall with a south aspect. It was then three years old, and is trained to wire projecting 3 inches from the wall. The garden is situated in a clay pit. The border was well trenched, also well drained with brickbats. The clay was burned and the roots of the tree were spread out on the border, and a covering of 4 inches of the border soil laid over the roots, bringing it to a raised mound. This year the tree has borne over forty Pears like the specimen enclosed; in fact, the tree has borne a good crop each year. I consider it a reliable and profitable Pear to grow. Last year was a very bad fruit season, yet Conference bore a splendid crop. The roots were well watered during July, August, and September.

Fontley, Furcham, Hants.

E. CARLYON.

THE FRUIT GARDEN.

APPLES AS CORDON ESPALIERS.

DURING recent years this system of training Apple trees in gardens has gained much favour. It has many points to recommend it. The most important ones are that if the training wires are fixed to run from north to south the trees receive the full benefit of light and sunshine, as well as free circulation of air among the branches—two essential conditions to the successful growth of this or any other hardy fruit. These conditions are not present to the same extent in a pyramid, bush, or standard tree; therefore fruit of larger size, better quality and flavour is obtained from Apple trees trained in this way than from any other form. Among other points in favour of the espalier is the fact that it takes up but little room, and is, therefore, for gardens of small extent especially, to be recommended. It lends itself also in a special degree to the more systematic cropping of the kitchen garden with vegetable and other crops

by dividing the garden into convenient quarters of various sizes. For the margin of walks Apples grown in this way are very attractive, both in flower and in fruit, and as a background to a border of hardy flowers most effective. They are also useful for screening the vegetable quarters from view. Horizontal or fan-trained trees succeed equally as well grown in this manner, but the cordon enjoys certain advantages over them. With cordons it is possible to cover the trellis at once with established fruit-bearing trees in one season, thereby giving a return of fruit to the owner at once instead of having to wait a considerable number of years, as would be the case with horizontal or fan-trained trees. Another advantage, especially to those with small gardens, is the fact that it is possible to plant a greater number of sorts on a limited space, securing thereby the charm of variety as well as a much longer succession of ripe fruit.

This simple form of espalier may be elaborated into many forms, such as covered ways

over walks, arches at intervals, or pillars and chains, but the simple espalier, as shown in the sketch, no doubt is the best. It is easily fixed by having strong iron posts at each end of the line with angle supports, and their bases in heavy stones and secured by molten lead being poured in. Should the espalier line be longer than 120 feet another strong post like the end ones should be fixed in the middle: these posts are for the purpose of tightening and straining the wires to give rigidity. The intervening posts need not be so heavy, neither will they require stone supports at their base, only a foot, as is common with ordinary hurdles.

The end posts should be 4 inches in diameter and of solid iron: 2-inch angle iron is strong enough for the intervening posts. The wires should be 10 inches apart, three-eighths of an inch thick, and the trellis when completed should be 5½ feet or 6 feet high from the ground level. The cordon trees should be planted 18 inches or 2 feet apart, according to whether the varieties are strong or moderate growers. Speaking generally, 18 inches is wide enough for the dessert varieties and 2 feet for the culinary sorts. Having such a limited space to grow in, it naturally follows that the cordons should be worked on the dwarfing English (not the French) Paradise stock. The soil should be deeply dug and manured with rotted manure. When they are established and growing freely a mulching of manure should be spread 2 inches thick on the surface of the soil over the roots in spring.

The system of pruning cordons must of necessity be one of restriction, namely, that which is commonly understood as close spur pruning. This is very simple, and consists, in the first place, in disbudding the wood growths when they are about half an inch long in spring, leaving only three shoots to grow in clusters, about 6 inches apart, the whole length of the stem. If it should turn out, as growth advances, that the tree is too crowded with foliage further disbudding must take place in order to avoid overcrowding and to enable the remaining shoots to gain full development and maturity during the summer and autumn. The new shoots should be shortened to within six or seven buds of the base the last week in July or the first week in August. The branches will then have attained nearly their full size, and this shortening of the shoots will help to swell and strengthen the base, as well as to plump up the buds. At the winter pruning these shoots should be cut back to three buds, when the whole of the treatment, as far as pruning goes, will have been carried out for the year. My experience goes to prove that once cordon fruit trees are got into condition for bearing good and regular crops—which they will do in the course of three or four years—there will be very little pruning required afterwards, possibly a little disbudding in spring, stopping the stronger shoots in summer, and the final pruning in winter. It generally happens that a few of the varieties planted fail to fruit so freely or so early as the others, making instead a stronger growth. Where this is the case the only effective remedy is to lift the tree from the soil, shorten its strong roots, replanting again immediately, and adding a little fresh soil.

The following limited and select list is submitted as consisting of some of the best known varieties, both of dessert and cooking: these are arranged in the order of their ripening as near as can be. Cox's Orange Pippin is without doubt the best dessert Apple we have at present, and when carefully harvested is in season for dessert from the end of October to the end of January (and much later than this sometimes),

so a greater proportion of this variety should be planted than of any other.

Dessert.—Red Juneating, Irish Peach, Devonshire Quarrenden, Worcester Pearmain, Wealthy, James Grieve, Okera, King of the Pippins, St. Edmund's, Ribston Pippin, Cox's Orange Pippin, Mother, Chas. Ross, Mabbott's Pearmain, Washington, Blenheim Orange, Hubbard's Pearmain, Scarlet Nonpareil, King of Tompkin's County, Baumann's Reinette, Lemon Pippin, Lord Burleigh, Duke of Devonshire, Fearn's Pippin, Court Pendu Plat, Sturmer Pippin, and Allen's Everlasting.

Cooking.—Keswick Codlin, Lord Suffield, Lord Grosvenor, Cellini, Ecklinville, Grenadier, Stone's, Blenheim Orange, Golden Noble, Warner's King, Bismarck, Mère de Ménage, Royal Jubilee, Beauty of Kent, Wellington, Lane's Prince Albert, Newton Wonder, Bramley's Seedling, Alfriston, Northern Greening, and May Queen.

OWEN THOMAS.

FRUITS IN SEASON.

APPLE MABBOTT'S PEARMAIN.

THIS Apple, the subject of our illustration, is an old dessert variety of great excellence. It is a mid-season variety, being in season from November to January. It is one of the most prolific bearers, as well as one of the hardiest sorts we have, succeeding well as an orchard standard. It is of medium size and handsome appearance, the general colour being orange yellow with streaks of red on the sunny side. Most people prefer a dessert Apple having a sweet flavour, but there are many others who prefer an Apple with a brisk and sub-acid flavour. To those in search of one possessing these qualities this Apple may be specially recommended.

A GOOD NOVEMBER PEAR—THOMSON'S.

MANY Pear growers do not give this variety room in their gardens, as they depend largely on Doyenné du Comice, but I think Thomson's should not be overlooked. Though it may not be considered equal to the variety named, it is an excellent fruit. At Syon this Pear is a little later than Doyenné du Comice, but that may not be the case in all gardens, as our trees are on a cooler site, and the soil causes great difference in ripening. It also does not succeed so well

APPLE MABBOTT'S PEARMAIN. (Slightly reduced.)

on the Quince; indeed, to get the best results it should be double grafted and given a warm wall, and then the fruit will be of splendid quality. It is not suitable for heavy clay soils unless specially prepared, as grown thus it cracks badly. Given good culture, however, the tree is quite hardy, and the return is excellent; indeed, with us it fruits when others fail. This is one of the best of the November Pears, and though not large it is a nice size for dessert, and is always asked for by those who like quality and do not care for mere size.

O. T.

BOOKS.

Some English Gardens.*—Mr. Elgood's delightful garden pictures are so well known that it is almost superfluous to dwell on their merit. The reason of his success, apart from, and yet in closest connexion with, his artistic ability is not far to seek, and is found in his own true love of a garden and intimate sympathy with the varied beauties of plant life. In this handsome folio volume—on whose production publisher, printer, and reproducer may alike be congratulated—fifty garden pictures are gathered together from places throughout the length and breadth of the British Isles. There are scenes in the gardens of some of the lordly palaces of the English Renaissance, such as Hardwick and Montacute; in those that have been made in later days around places dating from a remoter antiquity—some of them ancient fortresses—Berkeley, Crathes, Kellie, Penshurst, and Compton Wynyates; of ancient manors, beautiful with the timber structure and ornament of Tudor days, such as Speke and Great Tangley. From these, whose buildings dominate the garden design, to the modest flower border of the labourer's cottage, the same story is told throughout; of that delight in the beauty of flowers that has so strong a hold of English hearts, and of the many pictures the gardens offer to the eye and mind of the sympathetic artist. The reproductions, by the three-colour process, though not all equally successful, are a good example of the great progress that has been made of late in this remarkable development of the photographic art. Specially successful plates are "The Pergola, Great Tangley," page 8; "The Pool, Bramham," page 16; "The Yew Alley, Rockingham," page 34; "The Yew Walk, Crathes," page 42; "Ramscliffe: Orange Lilies and Monkshood," page 58; "The Yew Arbour, Lyde," page 107; "Phlox and Daisy," page 112; and "Michaelmas Daisies," page 122. The letterpress, by Miss Jekyll, consists not only of descriptive notes on the actual places, though the description is sufficient to present to the receptive reader a fairly complete idea of the environment of the actual subject. It contains also a good deal of critical observation, and draws attention to various matters that are of special interest and importance in relation to the more thoughtful, and therefore more effective, aspects of modern gardening.

OBITUARY.

GEORGE THOMAS MILES.

THE sudden death of Mr. Miles on the 17th inst. will come as a painful surprise to his many gardening and other friends throughout the country. It is only a few weeks since we had the pleasure of meeting him at the new hall of the Royal Horticultural Society, when he appeared to be in the enjoyment of his usual health and good spirits. Those who can look back some twenty-five to thirty-five years ago will remember that Mr. Miles formed one of a band of gardeners as eminent in their day as any before or since. His contemporaries included Coleman of Eastnor Castle, Thomson of Drumlanrig (both happily still with us), Thomson of Clovenfords, Speed of

Chatsworth, Buines of Southgate, Barnes of Bicton, Henderson of Cole Orton, Frost of Dropmore, Tillery of Welbeck, Gilbert of Burghley, Ingram of Belvoir, and many others. At that time the greatest encouragement and impetus to horticultural exhibiting was given, and it is not too much to say that the shows of those days have rarely, if ever, been surpassed; Mr. Miles was then very successful as a grower and exhibitor of fruit and vegetables.

One of his great hobbies was Pine-apple growing, of which he was a master. He was one of the first to explode the belief that prevailed among gardeners of that day that a good Pine-apple could not be grown and fruited from the sucker in less time than from two and a half to three years. He showed how Charlotte Rothschild Pine (9lb. in weight), and other varieties in proportion, could be fruited in from ten to eighteen months. He was the raiser of an excellent winter fruiting variety named Lord Carrington.

Mr. Miles was born in the village of Clewer, in Berkshire, where he started his gardening career in the gardens of the Hon. Henry Ashley. He remained there four years, afterwards spending three and a half years in the gardens of Combermere Abbey, Cheshire. His next move was to Keele Hall, which at that time had a garden of great renown. Here he remained as journeyman

THE LATE MR. G. T. MILES.

and foreman for more than three years, when he was recommended by Mr. Hill as gardener to the then Earl of Carrington at Wycombe Abbey: this was in February, 1858. Those who have had the pleasure of Mr. Miles's friendship know only too well that he was never tired of speaking of the great kindness and encouragement he always received from the late and present Earl and Lady Carrington, whose confidence and friendship as gardener (and latterly as agent) he has enjoyed for the long period of forty-six years. Mr. Miles has left behind a name pregnant with good example in industry, faithfulness, and perseverance. He died in the seventy-fourth year of his age. The sincere condolence and sympathy of the gardeners of England will be extended to his widow and family. The funeral took place on Monday last at High Wycombe.

SOCIETIES.

WOOLTON HORTICULTURAL SHOW.

THE sixth show was held at the Church Hall, on the 9th inst., and the Lecture Hall and Boys' School proved altogether inadequate for the exhibits. The entries had risen from 317 to 426, a record for the society. The exhibits, as usual, were noted for their excellent staging, making the show

a very pretty one. Only a few of the more important classes will be noted, with the first prize winner in each case.

CHRYSANTHEMUMS.

Twenty-four Japanese, distinct: Mr. Joseph Stoney, gardener to F. H. Gossage, Esq., had some good fresh blooms that also secured the silver challenge cup presented by Mrs. W. W. Gossage. For eighteen Japanese, Mr. T. Clarke, gardener to J. Clarke, Esq., was first. Twelve Japanese: First, Mr. T. Keightley, gardener to P. W. Barr, Esq. Eighteen incurved: First, Mr. J. Stoney, with excellent blooms. Twelve incurved: First, Mr. F. Clarke. Twelve distinct Japanese, arranged for effect: First, Mr. G. Haigh, gardener to Sir W. H. Tate, with a pleasing combination. Nine vases, distinct: First, Mr. J. Wilson, gardener to Sir J. T. Brunner, Bart.

FRUIT.

Black Grapes, two bunches: First, Mr. W. Wilson, with good black Hamburgs. Mr. A. Hitchman, gardener to S. Sanday, Esq., had the best white Grapes in Muscat of Alexandria. Apples and Pears were well shown, the winners being Mr. G. Hammond, gardener to Colonel Ireland Blackburne, five first prizes; Mr. T. Lunt, one; Mr. E. Marshall, gardener to Mrs. Tod, one; Mr. J. McColl, one. Vegetables were largely shown, and filled the Lecture Hall. The chief prize-takers were Messrs. J. Glover, G. Hammond, R. Rothwell, T. Lunt, J. Honey, T. Keightley and Mrs. E. Sutton. The arrangements, as already mentioned, were excellent.

ECCLES AND PENDLETON HORTICULTURAL SHOW.

THIS show was held in the Town Hall on the 11th and 12th inst. The entries were quite up to the average. The Chrysanthemums in pots were not very numerous, and were all staked plants. For nine large flowering plants, not less than five varieties, the premier prize and the National Chrysanthemum Society's silver medal were won by W. S. Boddington, Esq. For three plants, single-flowered, the chief award went to Mr. J. Ashley, gardener to the Lady Annette de Trafford, Weaste.

Cut blooms were shown in considerable quantity, but lacked uniformity. For twenty-four cut blooms, twelve Japanese and twelve incurved, there were four competitors for the silver challenge cup presented by the late John Stanning, Esq. Mr. J. Stoney, gardener to F. H. Gossage, Esq., proved the victor with an excellent lot. A bloom of Bessie Godfrey in this exhibit secured the silver medal of the National Chrysanthemum Society for the best bloom in the show.

Twenty-four blooms (six incurved, six Japanese, six reflexed, and six Anemones): First, Thomas Woodward, Esq. Twelve incurved, distinct: First, Mr. S. Ollier, gardener to F. Ashworth, Esq. Twelve Japanese, distinct: First, Mr. J. Stoney. Twelve large varieties (six incurved and six Japanese): First, Mr. J. Kirkham, gardener to Miss Stanning, Knutsford. Eighteen large flowered, six varieties, with their own foliage: First, Mr. J. Quinn, gardener to Mrs. Boddington, Eccles. Eighteen sprays of singles, in six varieties: First, Mr. J. Ashley. Twelve blooms (six Japanese and six incurved): First, Mr. R. Wainwright, gardener to T. Gaddum, Esq., Pendleton, winning the silver medal presented by Councillor Bethel. For six blooms (three Japanese and three incurved), Mr. W. Holmes, gardener to W. S. Forbes, Esq., Eccles, had the best.

In the amateurs' section W. Woolton, Esq., secured the first prize and silver challenge cup, presented by Mr. Agnew, with a good exhibit. As showing the skill of this exhibitor ten first prizes stood to his credit. The third challenge cup, presented by J. T. Lewis, Esq., for amateurs, was well won by H. D. Ashcroft, Esq.

Among the non-competitive exhibits Mr. W. Elkin (chairman of committee, and gardener to Mrs. Agnew), as usual, contributed some fine Palms. Stewart Garnet, Esq., Pendleton, sent a number of decorative plants that embellished the stage. Mr. J. Greatrix showed wreaths, &c. Messrs. Dickson, Brown, and Tait, Manchester, sent a fine bank of Begonia Gloire de Lorraine, Ferns, &c. Messrs. Dickson and Robinson had a large collection of Potatoes. Mr. J. Bryan, who is the hon. secretary, deserves congratulations for such a successful issue to his hard work.

CUPAR AND NORTH OF FIFE HORTICULTURAL SOCIETY.

OWING to the lack of public support recently a crisis has arisen in the affairs of the Cupar and North of Fife Horticultural Society, and a meeting was held in the Corn Exchange, Cupar, on the 8th inst. to consider as to the advisability of discontinuing the show for a year or two. After full consideration it was agreed to carry on the show as usual, and the following office-bearers were appointed: President, Mr. D. C. Stenart; chairman, Mr. D. S. Edmond; vice-chairman, Mr. C. Dicker; secretary and treasurer, Mr. George Wood; committee, Messrs. Brown, Clark, Donaldson, Drysdale, McGregor, Mackenzie, Oliphant, and Reid. The desirability of holding a concert in aid of the funds was referred to the committee.

BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

THE meeting of this association was held at St. John's Rooms on the 10th inst. Mr. P. Garnish occupied the chair, and, notwithstanding the inclement weather, the attendance was good. The appointed lecturer for the evening was Mr. Wakefield, gardener to Mr. A. Shipley, Westbury-on-Trym, who took for his subject "Begonia Gloire de Lorraine and Gloxinias." He detailed the method of cultivation of these favourite flowering plants—potting composts, propagation, feeding, and general treatment in a practical way. Insect pests also received attention. Fumigating by the XL All Vaporising Compound was said to be the best of all methods for eradicating insect. A good discussion followed the lecture, and Mr. Wakefield received the heartiest thanks of the meeting.

Prizes for a vase of Chrysanthemums were awarded to: First, Mr. Francis Taggart (gardener, Mr. Binfield); second, Mrs. Colman (gardener, Mr. Spry); third, Mrs. Henry

* "Some English Gardens." After drawings by George S. Elgood, R.I., with notes by G. Jekyll. Longmans, Green, and Co., London, 1904. Price £2 2s.

Derham (gardener, Mr. Sease). Prizes for Potatoes were also awarded, the successful competitors being the Rev. — Harvey (gardener, Mr. Tracey); Mr. Francis Taggart (gardener, Mr. Binfield); and Colonel Bains (gardener, Mr. Young). Certificates of merit went to Mr. W. H. Butler (gardener, Mr. Finch) for Violets, and to Mr. A. Shipley (gardener, Mr. Wakefield) for three Begonias; a special being recommended for Mr. A. Hall (gardener, Mr. Ware), for an *Oncidium*.

CHRYSANTHEMUM SHOW AT BETH, N.B.

A VERY successful show of Chrysanthemums was held in the Town's House, Beth, N.B., on the 12th inst. The show was considered the best yet held by the society, and in the different sections there were several exhibits of great outstanding merit. The principal prize, a silver cup, presented by Mr. Bryce Knox, was awarded to Mr. Andrew Stewart, Mainhill.

EAST OF FIFE CHRYSANTHEMUM SOCIETY.

THE twelfth annual show of this society was held in the Co-operative Hall, Methil, on the 10th inst. Although the twelfth of the series, it is the first one which has been held in the parish, and this was humorously remarked upon by Colonel Johnston, East Wemyss, in his speech at the opening of the exhibition. The show was a most successful one, both in the points of quantity of exhibits and in their quality, all the departments including specimens of high merit. The leading prize, the silver cup presented by Dr. Dawson, Buchhaven, for twelve blooms of Japanese in twelve varieties, was won by Mr. Angus Robb, Dysart House, Dysart, with twelve blooms of superb quality; while Mr. D. M. Pryde's silver medal for twelve blooms was won by Mr. John Farmer. Other leading winners were Messrs. Black, Hampton, Short, Maule, Watson, Cook, Law, Dallas, and Bailey.

KIRKCALDY CHRYSANTHEMUM SOCIETY.

THE third show of this society was held in the Adam Smith Hall on the 11th and 12th inst., being opened on the first day by Miss Oswald of Dunmure, who spoke in enthusiastic terms of the beauty of the Chrysanthemum. The show revealed the continuous progress made in the cultivation of the Chrysanthemum in the district since the formation of the society, and there was a general agreement that both cut blooms and plants were considerably superior to those of last year. In the classes for cut blooms the premier honours were carried off by Mr. D. McLean, gardener to Mr. R. C. Munro-Ferguson, M.P., Ruth, Kirkcaldy, who secured the Challenge Cup, presented by Sir Michael B. Nairn, and also the Kirkcaldy Corporation medal. Others successful in these classes were Mr. A. Johnstone, R. Inverurie; Mr. J. Brown, R. dour House; Mr. A. Robb, Dysart House; Mr. W. Short, Ladhil; Mr. J. Patterson, R. dour House; and Mr. J. Dyth, Cockburnie. In plants several of the above also distinguished themselves. These classes were very fine, fruit and vegetables were excellent, and the competition strong. Among the successful competitors with fruit were Mr. A. Johnstone; Mr. D. Hamilton, Pitmillen; Mr. J. K. Brown, Dunmure, and several others. The committee are to be congratulated on the success of their arrangements.

BLAIRGOWRIE CHRYSANTHEMUM SHOW.

THE Horticultural Society held its first Chrysanthemum show at Blairgowrie on November 10, and there was general satisfaction at the prospect of a series of successful shows. Although some of the exhibits were hardly up to exhibition standard, there were many of excellent character, and it is confidently anticipated that another year there will be both more entries and keener competition. Cut blooms were the best feature of the show, but pot plants were capable of improvement. Early varieties were well shown in vases, and Mr. Collie, Drumkilloo, who was one of the judges, brought a number of superb large blooms, which served as an object lesson of perfect flowers. The show was opened by Captain Blair Oliphant.

MAIDENHEAD CHRYSANTHEMUM SHOW.

THE seventh annual show under the auspices of the Maidenhead Chrysanthemum, Fruit and Vegetable Society was held in the Town Hall recently, and was a great success. The arrangements, which were on similar lines to those of former years, were well made and admirably carried out by Mr. J. W. Stone (hon. secretary), Mr. J. W. Richardson (assistant hon. secretary), and the committee.

Mr. W. Hammond, gardener to Mrs. Lewis-Hill, Woodside, near Boulter's Lock, was the most successful exhibitor. He secured for the second year in succession the Maidenhead Chrysanthemum Society's Challenge Cup, value fifteen guineas, in the open class for forty-eight Japanese blooms, not less than twenty-four varieties. In all he gained eight first prizes, three seconds, and two thirds, every exhibit from Woodside being awarded a prize. The second prize in the open class above referred to was won by Mr. W. Watson, gardener to F. Cox, Esq., Harefield Place, Uxbridge.

In the class for twelve incurved blooms, distinct, Mr. A. J. Marsh, gardener to M. Hodgson, Esq., Morton House, King's-worth, Winchester, took first prize, and Mr. W. Watson second. The premier prize for eight vases of Chrysanthemums (Japanese) went to Mr. Turham, who also received the National Chrysanthemum Society's silver medal. The same society's certificate of merit for the best incurved bloom was awarded to Mr. A. J. Marsh for his Charles Curtis, while Mr. W. Hammond received a similar certificate for the best Japanese bloom in the show. The pots of *Gloire de Lorraine* Begonias on the stage attracted considerable attention. The premier prize for six pots of this pretty Begonia was awarded to Mr. J. I. Challis, gardener to A. Kennedy, Esq., Taplow, for a magnificent lot, while Mr. B. Allen, gardener to E. O. Preston, Esq., Melmoth Lodge,

Cookham, was awarded second prize, and Mr. W. Stephens, gardener to S. Heilbutt, Esq., Hollyport, third.

The groups of miscellaneous plants were effectively arranged, as were also those of Chrysanthemums, while the fruit and vegetables were staged to the best advantage. In the class for a collection of vegetables there was a record entry—eleven—but nine only were staged.

There were, as usual, several noteworthy exhibits not for competition. Mr. W. Broughton had most effective floral designs. Mr. W. Stephens, gardener to S. Heilbutt, Esq., Hollyport, showed a fine collection of Gourds. Mr. E. F. Such, of the Braywick Road, Nurseries, had a capital display in the corner near the Council Chamber. Messrs. W. Cutbush and Son, of Highgate, also exhibited. Mr. D. Inzamells, King's Grove, Maidenhead, had a unique show of seed Potatoes of the disease-resisting varieties from the best growing districts of Scotland (Forfarshire and Linc. Dushire).

SHEFFIELD CHRYSANTHEMUM SOCIETY.

FOR many years the annual show of this well-known north country Chrysanthemum society has been regarded as one of the best of its kind in the United Kingdom, and the display on the present occasion was no exception to the rule. As a matter of fact, in certain respects it was distinctly ahead of any previous exhibition, as on Friday and Saturday, the 11th and 12th inst., the return to their old quarters in the Corn Exchange enabled the committee to make a remarkably fine display and to offer additional valuable prizes. The very heavy charge for the use of the Cutlers' Hall during the last two years was crippling the society, notwithstanding the fact that almost £200 was received for admission to the show, and together with about one hundred guineas for subscriptions, provided a tangible sum to deal with. A sum of about fifty guineas was charged for the use of this historic building, and this item, contrasted with twelve guineas for the use of the Corn Exchange, will give some idea of the advantages offered in the latter place.

The show was a very fine one, and the new class designated the Lord Mayor's Vase Class, which was suggested by the judges last year, proved a great attraction to competitors as well as to the public. This competition was for eight vases of Japanese Chrysanthemums in eight varieties, three blooms of one variety in each vase, with Chrysanthemum foliage, which may be added on separate stems. Seven entries were received, and six of the entrants staged their blooms. Better Japanese Chrysanthemums have never been seen than those set up in the first and second prize exhibits. It was a battle of the giants, and the offer of £10, £7 10s., £5, and £2 10s.—£25 in all—was, no doubt, the reason why certain well-known growers had reserved themselves for this important event. The judges had a very difficult task in discriminating between the leading exhibits, and ultimately the blooms of Mr. E. J. Brooks, gardener to Lieutenant-Colonel Beech, Brandon Hall, Coventry, gained the premier position by half a point. His blooms of Henry Perkins were phenomenal, being large, well coloured, and deeply built, and other good flowers were Mr. F. S. Vallis, Bessie Godfrey, Ethel Fitzroy, Mrs. Geo. Mileham, Mrs. Barkley, Mme. Paolo Radalli, and Mme. Gustave Henri. The last-named spoilt the rest, although they were good blooms of the variety. Uncomfortably close was Mr. F. S. Vallis, Broadham Fruit Farm, Chippenham. His series of blooms were beautifully finished and even, and it was easy to be misled into thinking they should have been placed first. His blooms of Mr. F. S. Vallis were the finest we have seen, "superb" aptly describing their quality. Blooms, too, of Mrs. F. W. Vallis, President Viger, Bessie Godfrey, Mrs. Barkley, and General Hutton were typical representatives. Mr. C. Crooks, gardener to the Dowager Lady Hindlip, Droitwich, was third with a fine lot of flowers; and Mr. F. J. Clark, gardener to Mr. Mark Firth, Leicester, was fourth, his blooms of Mr. F. S. Vallis being grand.

The south triumphed with incurved blooms. In the class for twenty-four blooms, in not less than eighteen varieties, Mr. W. Higgs, gardener to Mr. J. B. Hankey, Leatherhead, was a good first with large, well-developed incurved blooms of globular build. Noteworthy flowers were G. W. Matthew, Lady Isabel, Frank Hammond, Maurice Sargent (new), Fantia Ralli, Talene, Duchess of Fife, Miss E. Seward, Mrs. F. J. Jolson, Mrs. B. J. Jones, W. Pascoe, and Countess of Warwick. A very fine display secured second prize for Mr. G. W. Drake, Cathays Terrace, Cardiff, who had specially good blooms of May Phillips, Miss E. Seward, Frank Hammond, and M. O. Demmelenyere (new). Mr. Charles Jennings, gardener to Mr. F. W. Jameson, North Ferry, East Yorks, was third, having many blooms of good quality. There were four exhibitors in this class.

The seven exhibits in the class for twenty-four Japanese blooms, in not less than eighteen varieties, made a striking display. In this instance Mr. F. S. Vallis easily asserted his superiority, winning premier honours with blooms of good quality. They were beautifully even and well coloured, and set up with considerable skill. Striking examples were those of Mr. F. S. Vallis, Valerie Greenham, Mrs. F. W. Vallis, Chry. Montigny, President Viger, Mme. Carnot, Mme. Robertur, W. R. Church, J. H. Silsbury, Mme. Paolo Radalli, Miss Stoddard, and others. The second prize was won by Mr. E. J. Brooks, also with a good set, though with less colour and finish than those in the leading stands. Henry Perkins, Duchess of Sutherland, W. R. Church, J. H. Silsbury, General Hutton, and Miss Olive Miller were blooms of high quality in this exhibit. Mr. Charles Jennings was again third, and Mr. Drake fourth.

Mr. F. J. Clark was first for twelve Japanese, distinct, showing good blooms of Mr. F. S. Vallis, Marg. Venosta, W. R. Church, Mildred Ware, Duchess of Sutherland, and Mrs. Barkley. In this instance Mr. Drake was the only other exhibitor, and he was placed second.

Mr. Higgs was again to the fore in the class for twelve incurved, distinct, showing large and even blooms of good form. Mr. Drake again was a good second, and Mr. Jennings a creditable third.

The distinct classes were well contested in most instances. Messrs. J. D. Ellis, J. Colley, S. Roberts, M.P., C. Cook, J. G.

Graves, J. F. Montague, Alderman G. Senior, and Mrs. A. Barnes being the chief prize-winners.

Amateurs showed remarkably well, many of their exhibits being most commendable. Both Japanese and incurved flowers were shown well, the latter particularly so. Could these growers combine, they could stage a collection of some of the best incurved blooms ever seen. The principal prize-winners were Messrs. R. Smith (who won four first prizes), J. W. Smith, W. Smith, J. Wright, W. T. Anderson, J. Booth, E. Johnson, and T. Lygo.

Cottagers are given special encouragement, and as many as eight prizes are awarded in each class. Their exhibits were specially good, the blooms of the incurved type being especially praiseworthy. Mr. T. Fletcher won three first prizes, and other successful exhibitors were Messrs. W. Fenwick, H. G. Betts, F. May, W. Crawshaw, F. O. C. Dale, T. W. Toulson, and J. Sellars.

The affiliated societies' class is always interesting, and is for twelve Japanese and twelve incurved blooms, in not less than eighteen varieties. The Nether Hallam Chrysanthemum Society won the first prize for the third time in succession, and the cup now becomes their own property. The San Iun Chrysanthemum Society was second, and the Chesterfield Chrysanthemum Society third. Fifteen stands were set up in the class for six blooms of the *Kumde* family of incurved, to embrace two blooms each of Mrs. G. Rundle, Mr. Geo. Glenn, and Mrs. Dixon. This was a lovely display of these dainty flowers, and the competition was open to cottagers. Of the eight prize-winners Messrs. W. Fenwick, T. W. Toulson, and W. Crawshaw were the leaders. Groups were very good, and added very materially to the beauty of the show. In this instance Messrs. J. G. Graves, C. Cook, and Alderman G. Senior, J.P., were the prize-winners.

The trade made a number of charming and interesting displays. Mr. S. W. Seagrave, Cheadless Nurseries, Sheffield, had a beautiful group of stove and greenhouse plants (gold medal); Messrs. Artindale and Sons, Sheffield, a magnificent array of decorative exhibits (gold medal); Messrs. Hiram Shaw and Sons, group of stove and greenhouse plants (silver-gilt medal); Messrs. J. Peel and Sons, a grand collection of Apples and Pears (silver-gilt medal); Mr. C. J. Ellis, group (silver medal); Mr. R. J. Jones, Lewisham, S.E., thirty-six cut blooms, new Japanese Chrysanthemums (silver medal); and Mr. W. Wells, Limited, a small collection of Chrysanthemums. To Mr. M. H. Willford (secretary), Mr. J. G. Newsham (treasurer), Messrs. R. Gascoigne and H. Slaney (trustees), and a very able committee much praise is due for the excellence of the arrangements.

BANBURY CHRYSANTHEMUM SHOW.

THE Countess of Jersey opened the annual Chrysanthemum show at Banbury recently in the presence of a large and fashionable assembly. From the president (Lord North) to the humblest member of the committee all the officials worked hard for the success of the show, which has now become one of the best displays in the Midlands. The Countess of Jersey, in a very graceful speech, referred to the last occasion on which she opened a Chrysanthemum show, which was at Sydney, when Lord Jersey was Governor of New South Wales. She had learnt with great interest that the Banbury Society had been in existence eighteen years, and had done a useful work in enhancing the growth of the "golden flower," and she noticed that the show was peculiarly profuse in that colour. The show was of all-round excellence. The Banbury Challenge Cup, value 25 guineas, for twelve vases of twelve varieties, was won by Mr. F. J. Myers of Charlton House, and in the opinion of the judges they were the finest blooms they had seen, the second in point of excellence being shown by Mr. W. C. Cartwright of Aynho Park, and the third by Mr. A. R. Motion of Upton House. The Mayor's Challenge Cup for dessert table decorated with fruit and flowers was won by the Marquis of Northampton, Castle Ashby, and it was a very close competition between this and the display of Mr. W. C. Cartwright, who won the cup last year. The cut flowers were above the average, and the fruit classes were exceptionally well filled, whilst the vegetables were a record. Certificates of the Chrysanthemum Society were awarded to the winners of the challenge cups. The judges were Mr. W. L. Bastin, Buscot Park, Faringdon, and Mr. W. F. MacDonald of Whetstone, Edgbaston, Birmingham.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi, W.C., on Monday week. Mr. Charles H. Curtis presided. Sixteen new members were elected. The death certificate of Mr. James Tivendale, No. 370, was produced, and the secretary was instructed to pay the amount standing to the late member's credit to his widow, being his nominee. Six members were reported on the sick fund.

ABOYNE HORTICULTURAL SOCIETY.

AT the annual meeting of this society, held at Aboyne, N.B., on the 5th inst., a very satisfactory financial report for the past year was submitted by the secretary, Mr. Cowie. It showed a gross income for the year of £108 18s., and a balance to the credit of the society of £50. The office-bearers were elected, Mr. Cowie being succeeded as secretary by Mr. Wilson, The Gardens, Forest of Birse Lodge.

MEIGLE HORTICULTURAL SOCIETY.

AT a recent meeting of the committee of this society it was decided to endeavour to arrange for a series of lectures on horticultural subjects during the coming winter. It is hoped that it may be possible to secure a sufficient number of competent lecturers, and the services of a highly-qualified expert from England have already been obtained. The date of the annual show was also fixed. It will be held on August 12.

THE GARDEN

No. 1724.—VOL. LXVI.

DECEMBER 3, 1904.

BRITISH FRUIT INDUSTRY

A FRUIT GROWERS' UNION.

IN the *Standard* there appeared recently a timely and important letter called "The Fruit Industry: Experiment in Organisation." The article relates to an attempt made by the fruit growers of the Evesham district of Worcestershire to place their industry on a more satisfactory basis, especially in reference to marketing conditions, which has been attended with results that are not only exceedingly gratifying in themselves, but also constitute one of the most hopeful phases of that movement in favour of combination on the part of the agricultural classes that is steadily winning increased favour throughout the United Kingdom. Some of the points brought clearly out in this letter as bearing on the importance of a better and more equitable system of disposing of the produce of the garden and orchard are the following: An area of about 9,000 acres is devoted to the culture of hardy fruit and vegetables in the Vale of Evesham. Experience in the past has proved that where only ordinary crops were gathered in it was hardly possible for the growers to make a living out of the business. The primary reason for this was the defective system then in vogue for marketing the produce, the general practice being to dispose of the crops to local dealers, the dealers selling again to the wholesale merchants, from whom the retail shopkeepers secured their supplies for disposal to the public. The profit which the grower ought to have secured to himself thus went to the middleman for simply acting as a go-between the grower and the merchant.

To remedy this evil some of the largest growers in the district resolved in the spring of the present year to resort to co-operative effort in establishing an organisation which they called the Evesham Growers Association, Limited, in affiliation with the Agricultural Organisation Society. The aim of this body is to reduce the middleman element to the smallest possible dimensions. To this end the growers constituting the combination send their produce to a general depot, where the sale of it is arranged by a manager, who, communicating each day with dealers in large centres in the Midlands, North of England, South of Wales, Scotland, and Ireland, executes those orders direct, without the intervention of any agent. The manager also sends out a weekly price list to shopkeepers

throughout the United Kingdom, quoting prices at which direct supplies can be forwarded, and a good business has been developed in this way. During the course of the present season the association has disposed of fifty-five tons of fruit to the Wholesale Co-operative Society of Manchester for jam-making alone. Still further, the Evesham society has organised a system under which it sends boxes of fruit direct to the consumer in return for charges which includes delivery free. The greatest care is taken in packing and grading, each fruit being wrapped in a piece of soft paper bearing the society's official stamp. In their rôle as a trading society the association adds to its own supply by purchasing from local growers who are not themselves members. Altogether the amount of fruit and vegetables (mainly the former) sold by the association since it came into existence in the spring is placed at close on 1,000 tons. The article concludes:

"The facts were stated to constitute a noteworthy development in British fruit growing, and one that may undergo still further important development, considering that a movement of only a few months old has already attained so sturdy a growth. It may, in some respects, represent a revolt against the middleman, who, rightly or wrongly, has hitherto been accused of being the chief taker of profits; but it also represents an earnest attempt to organise an important branch of our agricultural (and horticultural) industries on lines that are eminently practicable, and should also be commercially sound."

In our opinion the lead given by the fruit-growing co-operatives of Worcestershire deserves to be followed by fruit growers in every county where fruit is grown on anything like a large scale, and ultimately we hope that a National Fruit Growers' Union, for the promotion and protection of this great industry, will be formed in some convenient and important centre, that would make it easy for the county societies to be affiliated therewith.

It is only by a practical and united combination on these lines that British fruit growers can ever hope to make fruit growing and preserving a great national and prosperous undertaking, as it should be. "Great things from small beginnings spring," and we earnestly hope that fruit growers in other parts of the kingdom will take note of the successful initiation of a union among fruit growers for the disposal of their produce, and hasten to follow their example.

POTATOES TO EAT.

It is, no doubt, very comfortable to be of "E. L. B.'s" opinion that "whatever is is best"—that the vegetables and fruits which fill ninety out of a hundred gardens need no improvement, or at least are "good enough." But it is a disastrous frame of mind as regards progress of the public taste, which has never yet been, and never will be, advanced by mere acquiescence in the popular lack of discrimination. And the question of choice between one vegetable or one fruit and another cannot be shelved by saying "tastes differ," or "everyone to his taste." There is such a thing as good taste and bad taste. In France, for example, the public taste is greatly truer and more refined than in England. Small, high-flavoured Grapes are bought in preference to large-berried, coarser sorts, while it is certain that in England the Chasselas (Royal Muscadine) would have no chance whatever of sale against Gros Colmar. The French preference for yellow-fleshed Potatoes is not a mere foreign superstition, but is due to their undoubted superiority of flavour. "E. L. B." decries them as "close." They are certainly not balls of dry starch—to myself almost difficult to swallow—as are so many of these popular modern white Potatoes. But I have never heard the Ashleaf blamed for its texture, and good yellow-fleshed Potatoes are of the same consistency, to my mind delicious—Chestnut-like, betwixt wax and flour. Undoubtedly the demand for dry white flour comes from the English fashion of regarding Potatoes as sponges for mopping up gravy rather than as vegetables to be tasted on their own merits. The admirable Potato salads one gets in France, and a variety of other Potato dishes, demand Potatoes which will not fall to pieces when cut. The best yellow sorts, when boiled in their skins and peeled afterwards, are excellent taken in the fingers and eaten cold with salt. No white Potato will stand this test. Please "E. L. B." try this without prejudice.

With regard to size of tuber I did not write about the shops, but about the shows. If at the Crystal Palace or any other exhibition two dishes of, say, Up-to-Date were staged—one of moderate, the other of gigantic size—can "E. L. B." deny that the huge tubers would win? And this practice is the more imbecile if the trade dislikes big tubers.

An important point I had almost forgotten about white *versus* yellow Potatoes is this—that the yellow colour denotes not only flavour but the presence of the flesh-forming constituents which are of higher nutritive value than the starch; therefore the white-fleshed craze is actually robbing the poor man of his food!

We should make great strides towards a better public taste if the truth were grasped and acted on that shows are not for the glorification of the exhibitors, but for the education of the nation. If the judges would

resolutely and of one accord refuse prizes to coarse, flavourless produce, it would gradually disappear from the exhibition table and so from the market. Such a change of opinion would force our raisers to aim at quality instead of appearance and bulk, and some of us would live to see the desired cheap, long-keeping Muscat Grape and disease-proof Potato fit to eat.
G. H. ENGLEHEART.

LILIES IN A NORTH COUNTRY GARDEN.

I THINK that a few notes on Lilies grown in Durham may be of interest. My garden is a small one and mainly devoted to Lilies. It has an open exposure facing south-east, and the natural soil is a poor dry hungry loam, so that I am obliged to supplement it by the plentiful addition of peat, river sand, leaf-mould, good rich loam, and old rotten cow manure, the latter applied as a top-dressing in November or December. We suffer much from late spring frosts and from frequent damp dull days, so that the conditions are not very favourable. The Lilies are grown either on low rockeries or on a slightly sloping border. The Martagons take pride of place for hardiness, reliability, and wealth of flowers. The common Martagon does well both in sun and shade, and I have several forms of it varying in colour, spots, and splashes of purple. *M. album* is a lovely Lily, and does very well year after year. I have two forms of it, one with tall stems and very white flowers, the other dwarfer with smaller flowers set closer together and inclined to a creamy white. The tall form is the better. *M. dalmaticum* also does well, some of the spikes this year having between thirty and forty flowers. It varies from light purple to a deep dark maroon, almost black. *Humboldtii*, grown in a mixture of loam and peat, does fairly well; my best spike this year had fifteen blooms, but it is quite eclipsed by the variety *magnificum*, which is a truly magnificent flower. Its handsome blooms of golden yellow, stained and spotted with purple, are very freely produced, and it blooms the first year after being transplanted, which the type does not, requiring two or three years to produce a good spike. *L. Hansonii* this year was very good, and is a sure bloomer if it escapes late spring frosts. Last year the bloom on four clumps was entirely destroyed by the frost which we had at Easter. The bulbs, however, did not seem to suffer at all, and the spikes came up strong early last March. The old *L. pomponium* was the first Lily to bloom here (on June 6) this year, and a couple of strong clumps made a good show of its vermilion flowers. It was three weeks before its near relative, *pomponium verum*, but the latter is much the finer plant both in foliage with its narrow white line and its beautiful bright scarlet flowers. It does well here and increases. *L. pardalinum* is another grand Lily which should be in every garden. It grows very strongly and increases rapidly. Some of the stems here this year were 8½ feet high. It does best in slight shade in a peaty soil, but will do well in full sun in loam if watered occasionally. The varieties *californicum*, *Johnstonii*, and *Michauxii* are all handsome flowers, and easily grown in peat. *L. pardalinum* minor, with smaller flowers but very graceful habit, is a beautiful variety, but does not increase much. *L. Dalhansonii* and *Marhan* both do well, but I do not think these hybrids are any improvement on their parents, and the same may be said of several hybrids of *pardalinum*, but all are handsome and well worth growing. *L. testaceum* and

L. colchicum are both splendid Lilies, sure bloomers when established and left alone, and will stand for many years on the same spot. They are grateful for a good mulch of cow manure every autumn. *L. chalcedonicum* in two forms—one with numerous small black spots and the other unspotted—does very well in full sun and in a dry season. Last year it was poor, but this year has bloomed finely. The clumps should be left alone for four or five years or even longer if doing well, as it is one of the Lilies which resents removal, and in any event it (as most other Lilies) should be transplanted early (beginning of October) if removal is necessary.

South Bailey, Durham. T. MADDISON.
(To be continued.)

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

December 6.—National Amateur Gardeners' Association meeting.

December 8.—Annual Meeting and Dinner of National Rose Society; National Amateur Gardeners' Association, Annual Dinner.

December 13.—Royal Horticultural Society's meeting at the New Hall, Vincent Square; Exhibition of Colonial-grown Fruits, and of Home, Colonial, and Foreign Jams and Preserved Fruits.

Royal Horticultural Society.—At the general meeting of Fellows, held last Tuesday afternoon, twenty-nine candidates were elected Fellows, including Lieutenant-Colonel E. H. Berkeley, the Hon. Mrs. Horace Darwin, Mrs. Wolley-Dod, the Hon. and Rev. W. C. Ellis, the Right Hon. Herbert Gladstone, M.P., Mrs. Herbert Gladstone, and Mrs. Sebag-Montefiore. The next exhibition of this society will be a show of Colonial-grown fruit, which will be held in the Centennial Hall, Vincent Square, Westminster, on Tuesday and Wednesday, the 13th and 14th inst. As this is the first exhibition of the kind ever held it should prove of great general interest, especially at the present time, when so much public attention is being directed to our Colonies and their capabilities for supplying the home markets. An exhibition of home, Colonial, and foreign preserved and bottled fruits, jams, &c., will take place at the same time, and will afford an opportunity of comparing the products of the various places. This show will be open on both days from 10 a.m. to 10 p.m., and the public will be admitted at 1s. each person.

National Rose Society.—I beg to inform you that the twenty-eighth annual general meeting of the National Rose society will take place at the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Thursday next, the 8th inst., at 3.30 p.m., to receive the report of the committee; to pass the accounts; to elect the committee and officers for the ensuing year; and for the transaction of other general business. The twenty-eighth annual dinner will take place at the rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on the same day at 5.30 p.m., C. E. Shea, Esq., in the chair. Members and their friends are earnestly invited to attend this pleasant annual gathering of rosarians.
EDWARD MAWLEY, *Hon. Secretary.*

The election of the officers and committee of the National Rose Society.—As a member of this society I have just received, among other papers, one containing the names of the proposed committee for the ensuing year. Members are invited to strike out any name they please, and add others, providing the list does not exceed forty. So far, all is very fair; but when I read that the paper must be presented *in person* at the annual meeting, then it looks to me a very one-sided election, completely giving the power into the hands of such members as can be present. Surely in a society calling itself National some better arrangement than this could be devised, for there are among its 1,000

members many who cannot possibly attend, but who nevertheless could record their vote by proxy or in some other way. This arrangement seems to be designed to keep the affairs of the society in the hands of a "clique," and I strongly protest against it. What we require is a committee thoroughly representative, and this will never be if the voting is delegated to the home members only.—COUNTRY MEMBER.

"Forests, Wild and Cultivated." On Friday evening, the 25th ult., a lecture on this subject was delivered by Dr. Augustine Henry, in the Ewart Library, Dumfries, under the auspices of the Dumfriesshire and Galloway Natural History and Antiquarian Society. Mr. G. F. Scott-Elliott, M.A., F.L.S., president of the society, occupied the chair, and there was a good attendance of the members and the general public. Dr. Henry gave a very able lecture, and close attention was paid during its duration to his descriptions of the characteristics of natural forests and the trees of which they were mainly composed, as well as to the part devoted to the consideration of cultivated forests and their treatment. The lecture was fully illustrated with limelight views, and these were well chosen so as to emphasise many of the points of the lecture. Dr. Henry gave an interesting description of the principles of modern forestry and their application. On the motion of Mr. S. Arnott, seconded by Mr. R. Service, Dr. Henry received a most hearty vote of thanks.

"In Cyderland."—It is always a pleasure to record a successful entertainment when it is given for a charity, but the pleasure is greater when the entertainment itself is praiseworthy. On Thursday evening in last week a musical play called "In Cyderland" was performed by the Hurst and Son Musical Society, in aid of the Gardeners' Royal Benevolent Institution, which will benefit to the amount of £50. The words of the play were written by Mr. R. Carey Tucker, and the music composed by Mr. Edward Sherwood, son of Mr. N. N. Sherwood, the head of the well-known firm of Messrs. Hurst and Son. The Cripple Gate Theatre, in which the play was performed, was crowded, and the audience thoroughly enjoyed the bright music and clever lyrics. Mr. N. N. Sherwood received an ovation when entering the hall, and was heartily congratulated on his restored health. Among those present were Mr. R. C. Smith-Carrington, Mr. E. W. Elliott, Mr. W. P. Atkinson, Mr. G. J. Ingram, and Mr. Alfred Watkins. The composer conducted the orchestra, whose performance was excellent throughout. The honorary secretary of the society is Mr. Washington.

Weather in North Cornwall.—From this district on the 24th ult., a correspondent writes: "We had a terrific thunderstorm with 5½ inches of snow on Wednesday, and 15° of frost last night."—A note from Worcestershire records 25° of frost.

Presentation to a gardener.—A "Former Laurick foreman" sends us the following: Mr. James Begg, having completed his fiftieth year as gardener to Sir Robert Jardine, Bart., at Laurick Castle, substantial recognition of his long career was recently made by a number of the men who have served under him. Pleasant recollections of the time spent with Mr. Begg impelled the many men who have passed through his hands during the long period in which he has been at Laurick to present him on the attainment of his jubilee with some token of their gratitude. In the hands of Mr. A. Dewar (Dunkeld), Mr. J. Troup (Castle Milk), and Mr. McLean (Balgray), the project made such good progress that they were able to present Mr. Begg with a gold watch and chain, while Miss Begg, almost as much respected and esteemed by the workmen as Mr. Begg himself, was made the recipient of a gold brooch. For many years Mr. Begg was a very successful exhibitor. He is such a good all-round gardener that his career is often pointed to as a guide to younger members of the craft throughout Scottish gardens. The completion of his jubilee as gardener at Laurick was an important event to many gardeners in Scotland, and the occasion was seized upon to give some tangible proof of their appreciation of pleasant memories of earlier days and the useful and practical training they received.

Eupatorium arizonicum.—This autumn-flowering Eupatorium is of recent introduction, and a good addition to hardy perennial plants. Also as a pot plant it is worth growing for the market. It grows dwarf and bushy, the leaves small and light green; now they are covered with large umbels of white flowers, which last more than a week in water. It can easily be propagated by cuttings, and should be in the border, rockery, or in large groups in every garden.—WILLIAM MULLER.

Polygonum equisetiforme var. australe.—It seems that this half-shrubby Polygonum does not do well in England or Ireland, but here it is a most useful flowering plant in the autumn. The long, thin branches droop in an elegant manner, and are covered in the autumn with great numbers of small white flowers. This is one of the best plants for dry rockeries. A good place for it is a wall, as it is in the famous garden of Mr. C. Sprenger, where the branches can spread in all directions. For cutting it is very useful. Everyone is filled with enthusiasm who sees this graceful plant cultivated as I have mentioned.—WILLIAM MULLER, *Naples*.

Red and blue flowers for autumn. I have seen no blue flower so good as *Salvia patens*, and no red better than *Pentstemon Newbury Gem* for embellishment of the flower garden in late autumn. I recently saw a bed, some 60 feet long by 8 feet or 10 feet wide, wherein among other things were planted irregular masses of these two plants. Parts of the colour scheme were daring, for the rich blue of *Salvia patens* was side by side with the red *Pentstemon*. The mass of blue was contained behind that of the red, so that the two colours quite ran into each other. Two plants of such bright colouring as these, that will flower throughout the autumn, even into November, are worth planting. *Tropaeolum tuberosum*, with its curious red and yellow flowers, is a plant not often seen, yet for clambering over a root or rough piece of wood, or even rough stakes, a patch of it in the border is a pretty feature in late autumn.—Y. Z.

Calanthes and Dendrobium nobile at Buxted Park.—In THE GARDEN of the 12th ult., page 339, Mr. H. C. Prinsep is good enough to give us the benefit of his experience in the cultivation of one of the most useful and attractive of our decorative Orchids. I have grown *Calanthes* in a Melon house, and know several places where this plan is adopted, but I have never yet met with such excellent results. I had the pleasure a few weeks ago of visiting the gardens at Buxted Park, and was perfectly astounded to see such plants. Mr. Prinsep has certainly hit upon the right plan, and he makes his treatment so plain that no one can fail to understand it. Those who wish to grow *Calanthes* well should follow Mr. Prinsep's method. *Calanthes* are not the only Orchids grown well at Buxted Park. At the time of my visit I saw the finest lot of *Dendrobium nobile* it was ever my lot to see; every plant was in perfect health, many of the growths being over 4 feet in length and 3 inches in circumference. I am sure that many gardeners, like myself, would be glad if Mr. Prinsep would give us the benefit of his experience in the culture of *Dendrobium nobile*.—T. B. FIELD, *Ashwellthorpe, Norwich*.

Epiphyllum delicatum.—This very pretty Epiphyllum, exhibited by Messrs. William Bull and Sons at the meeting of the Royal Horticultural Society on the 15th ult., is at present little known, though it was put into commerce a couple of years or so ago. It was imported from Brazil and first exhibited in the autumn of 1898, when a first-class certificate was awarded it under the name of *Epiphyllum truncatum* Princess, but subsequently the question arose whether it was really a variety of *E. truncatum* or a species distinct therefrom. On being submitted to Mr. N. E. Brown, of Kew, that gentleman assigned it specific rank under the name of *Epiphyllum delicatum*, which is now retained. From *E. truncatum* it differs in its somewhat more erect habit and strongly toothed branches, while the flowers are rather less oblique at the mouth of the tube. In

colour they are white, suffused with purple, which colour is deeper towards the centre than at the edges, while just at the entrance to the throat there is a ring of purple-lake, the long, protruding stigma being also of the same colour. The tint of the flowers deepens somewhat with age, as the freshly-expanded blossoms are paler than the older ones. Like the rest of its class, this Epiphyllum can be readily propagated by grafting on to stocks of the *Pereskia*. It is a matter for surprise that the many beautiful forms of Epiphyllum are not met with more often than they are, as the flowers appear at a welcome time. The only varieties of *E. truncatum* honoured by the Royal Horticultural Society have been tricolor in 1864, violaceum in 1869, and that above named. The spring-flowering *Gärtneri* and *makoyanum* are specifically distinct from these.—H. P.

Inferior Pears.—I think Pears may well be given more attention; not that I advocate new varieties for mere variety's sake, but by the introduction of really good fruits we could with advantage weed out some of the inferior ones. Soil and locality have a great influence on fruits, and what may be useless in one garden is good in another; but there is no doubt whatever that some of our late October and November Pears are not worth growing. I will give a short list. Very poor Pears are the following: *Beurré Bachelier*, large and a regular cropper, but of very poor quality, and a fruit not worth storage. Another with very similar qualities is *Nouveau Poiteau*. This I find described as a first-rate Pear, but it is not so with us. General Toddleben is poor, though in some soils it is much liked, and *Soldat Esperen* is at times second-rate. There are other sorts that do not vary, and a few, but none too many, are always reliable as regards quality. Those who plant fruit for home supplies would do well to study the varieties previously, their behaviour, and last, but not least, their eating qualities. A visit to the nearest fruit gardens would be well repaid.—W. S. B.

Pampas Grass.

The Pampas Grass (*Gynerium argenteum*) shown in the illustration was planted nine years ago. It has been greatly admired by all the visitors here. There is another beautiful plant, and together they are now carrying one hundred and four good plumes. The single specimen has fifty-six. —C. H. FOX (Gardener to Sir E. B. Mansel, Bart.), *Old Catton House, Norwich*.

Erica lusitana.

—Although March is the time we look to find flowers of this Heath, the mild weather experienced during October has made it so far forget itself at Kew as to open many of its flowers, several plants in the vicinity of King William's Temple being in almost full blossom. Although one of the loveliest of all outdoor Ericas, it is not often met with in quantity, owing to the fact that it is not so hardy as some of the others, and is apt to be injured or perhaps killed outright during a severe

winter. It is found in Spain and Portugal, and when Nature makes a large bush 6 feet or 8 feet high the branches have a plumose appearance, and are clothed with pretty, bright green leaves. The flowers are pure white, and are borne in great profusion. At Kew it has been out of doors for five or six winters, and has stood well with the little protection afforded by scattering some dry leaves about the roots, and a little hay among the branches on the appearance of frost. For such favoured localities as Devonshire, Cornwall, and South Wales this and other South European Ericas, such as *E. australis* and *E. arborea*, should be quite at home, and would well repay the expense and trouble of planting. A hybrid which promises to become a useful garden plant has been raised between *E. lusitanica* and *E. arborea*, and is being sent out by Mr. Veitch of Exeter.—W. DALLIMORE.

Chambre Syndicale des Horticulteurs Belges.—We have the honour to bring to your notice that our committee has decided to commemorate on Sunday, February 5, 1905, the twenty-fifth anniversary of the inception of this society. The nature and details of the ceremonial will be decided later.—H. DE WILDE, *Secretary*.

Phenomenal blooms of Japanese Chrysanthemums.—The new vase class for Japanese blooms, called the Lord Mayor's Vase class, because of the financial support given to the class by the retiring Lord Mayor, at the recent show of the Sheffield Chrysanthemum Society, proved a great success. Competition was keen, and there is reason to believe that, in certain specified instances, better Japanese blooms have never before been set up at any Chrysanthemum exhibition. The two varieties referred to are,

THE PAMPAS GRASS (*GYNERIUM ARGENTEUM*).

respectively, Henry Perkins and F. S. Vallis. The former trio of blooms was in the first prize exhibit of Lieutenant-Colonel Beech, Brandon Hall, Coventry (gardener, Mr. E. J. Brooks). Phenomenal aptly describes their immense proportions. They were of great breadth and depth. Each bloom was made up of broad petals that were quite 8 inches to 10 inches in length. Even form and build characterised each flower, and for this fine English-raised seedling they were ideal. This variety has been in typical condition this season, but nothing like the three blooms exhibited on this occasion. Mr. F. S. Vallis exhibited three blooms of his namesake, that for form and size have never been surpassed. This grower missed the first prize by the smallest possible margin.—D. B. CRANE.

Miniature-flowered Pompon Chrysanthemums.—Why the charming, small-flowered Pompons are not more extensively grown is a mystery. In conversation a few days since with a well-known Covent Garden florist, I was astonished to learn that these beautiful flowers are seldom seen. The flower-loving public appear to be surfeited with the Japanese Chrysanthemums. The small Pompons and single-flowered sorts are very refined, and there is no better material for vase decoration for display indoors. In so many ways these dainty flowers may be used for room decoration, and when not disbudded each spray is a picture in itself. Surely if some grower were to take in hand a few of the better sorts, grow them well, and ultimately send them to market in useful and attractive bunches, a demand would set in for the flowers and prove a success. We always grow a few of the better varieties, and among them Snowdrop, white, and Primrose League, its yellow sport, together with a pretty bronze sort named Katie Mannings, form a trio that it would be difficult to beat. This season we planted small pieces outdoors, in June, in rows rather close together, and they grew luxuriantly. In late October the plants were lifted and placed in large pots, and after getting established they were arranged in a cold house, where they are just coming into flower. They promise a display until the end of the year.—D. B. CRANE.

Celery Sutton's Superb Pink.—Now that the Celery season is at its height a word in praise of the above variety may not be out of place. Anyone wanting a first-class variety cannot do better than grow it. It is all that can be desired, having a sweet nutty flavour. This is the first season I have grown it, but it has gained preference here over such sorts as Leicester Red, Major Clarke's, Standard Bearer, and Wright's Grove Red.—J. S. HIGGINS, *Rûg Gardens, Corwen.*

The Glastonbury Thorn.—Of all the different forms of the common Hawthorn this is perhaps the most interesting, and certainly the most curious in its behaviour. When speaking of the Hawthorn we usually think of the flowers as having a setting of bright green, but in this case we find a variety braving November's fogs and bearing its white flowers on leafless branches. At Kew at the present time a tree may be seen in the avenue near the south end of the Temperate house covered with buds and expanded flowers; it looks very curious among the other Thorns. Its correct name is *Crataegus monogyna* var. *præcox*, its common name arising from the fact of its having originated in the village of Glastonbury. As a rule the flowers begin to open in November, and continue to expand throughout the winter. It is not usual for a really effective display to be made at any one time, though in the event of very mild and clear weather predominating in November a very good show is made. Last year the tree previously mentioned blossomed exceptionally well in November. It is increased by budding on stocks of *C. monogyna* or *C. oxyacanthoides*.—W. D.

Pernettya mucronata.—The prettiest outdoor effect at Kew at the present time is made by this shrub, three beds near the Azalea Garden being smothered with bright coloured fruits. The usefulness of this plant for general work is apparent from the fact of its being an attractive evergreen, a good flowering shrub, and one of the best that bear ornamental fruit. It has been in cultivation

since 1828; at that time it was introduced from the Magellanic region. When mature it rarely exceeds 2½ feet or 3 feet in height, and is often met with from 1 foot to 2 feet high. In appearance it is neat and bushy, the leaves being small and deep green. The flowers are pure white, and are borne in the leaf axils in May, though blossoms are sometimes to be found quite late in the year. The fruits vary in size and colour on different plants. Some are as large as those of *Symphoricarpos racemosus*, while others are only half as large. The colour varies from white to pink, rose, light and dark red. When planting in groups a mixture of colours should be made, and care should be taken not to plant too thickly, for it produces suckers freely, and if thick in the first place soon becomes a tangled mass, in which case the flowers and fruits are not seen to advantage. It is a shrub that does not care for much disturbance at the roots, and it prefers a rather heavy, cool soil. For beds on the lawn or groups in the front of a shrubbery it is an excellent thing, and is a shrub worth bearing in mind by planters.—W. DALLIMORE.

HESPEROCHIRON PUMILUM

YOUR contributor Mr. E. H. Jenkins (page 327), or perhaps I ought to say "W. I.," for he appears to have been the original "medium," has evoked a ghost which rather interests me, and upon the apparitions of which I can perhaps help to throw a little light.

Mr. Jenkins is probably quite right—he is certainly approximately right—in the date he gives (1880) of the flowering of *Hesperochiron pumilum* or *H. californicum* (or both) at the Hale Farm Nursery, Tottenham, for I have come across two of Ware's old catalogues for 1882 and 1883, from the former of which I extract the following description: "*Hesperochiron* (*sic*), a new genus of dwarf-growing alpine plants, introduced from the Rocky Mountains. Both species are perfectly hardy, easily grown, exceedingly floriferous, and when seen in masses form very effective objects. Although the two species are somewhat similar, yet they are sufficiently distinct to warrant their admission into the most select collection of rock plants. *H. californica* (*sic*) differs principally by its more robust habit, and with flowers and foliage slightly larger. Both species vary in colour from white to dark blue, and are usually found growing in damp situations. A beautiful figure appeared in my catalogue No. 58.—*H. californica*, 1s.; *H. pumilus* (*sic*) (*Vallarsia pumila*), 1s."

With regard to this description I have only to remark that I suspect the "dark blue" is, or was, "very like a whale," and still more like a nurseryman, and I doubt if these plants were ever "seen in masses," either at Hale Farm or in any nurseryman's or amateur's garden in this country, although the fact that the plant were so cheap is, of course, evidence that they were easily propagated or raised from seed.

In THE GARDEN for May 5, 1883 (Vol. XXI, page 399), I find the following note, signed "P. Sewell, York": "*Hesperochiron californicus* is a very dwarf and pleasing perennial. Its flowers are white, slightly tinged with rose towards the edge, much resembling those of a *Convolvulus* in general appearance. Some have distinct dark purple honey lines down the centre of the corolla lobes. The leaves are greyish green and hairy, and most of them paddle-shaped. From one crown will spring over a dozen flowers with as many leaves. The whole plant does not measure more than 6 inches across, nor its graceful flower-stem more than 3 inches high at most, while an expanded flower is 1½ inches across at the tips, its tube being about half as long."

One, or very possibly both, of these plants was sent to me years ago by the late Mr. Wolley-Dod, and one of them certainly survived for several years on my rockery, and, as I recollect, until after he had lost them himself.

I recollect, too, his telling me when he sent them, that in habit and general appearance they were very like *Oxalis acetosella*, and this is just the description I should adopt as my own recollection. The flowers were white with slight red or purple veinings, and, as a matter of fact, they were of little or no real gardening value, although the botanical interest was, no doubt, considerable. The plant had neither vigour nor exceptional beauty, and, here at any rate, though, as I have said, it lived for some years, it never made the smallest increase. The plant belongs, I believe, to *Solanaceæ*, but as I cannot, unfortunately, refer at once to the "*Index Kewensis*," I cannot say whether the more orthodox spelling of the name is with or without the "s," or whether the synonym "*Vallarsia*" has any claim to recognition. As to the name, whatever be its derivation or its meaning, if it has any, it will be better, I should say, to consider it as neuter, and to speak of *H. pumilum* and *H. californicum*. Anyway, we must not be asked to have it masculine and feminine at and in one and the same time and line, as in Ware's old catalogue, an error which is, I see, reproduced in Johnson's "*Gardening Dictionary*," the edition of 1896.

J. CARRINGTON LEY.

THE FLOWER GARDEN.

THE EREMURI.

NOW that the culture of these noble plants is becoming better known they are rapidly increasing in favour, and they form a striking feature in many gardens with their stately stems bearing long racemes of numerous flowers. The genus consists of about twenty-five species in all, most of which are natives of Central Asia, Turkestan being the headquarters of the family, with one from the Himalayas, others from Persia, Siberia, and Asia Minor. Of this number ten have been introduced into cultivation in our gardens at various times, although they are probably not all still represented, some having been lost owing to want of knowledge as to their requirements. Several of the species are really handsome plants, well suited for warm, sheltered positions, among low-growing shrubs or loose-habited plants which are not planted so closely together as to rob them of the sunshine necessary for the ripening of the crowns after flowering. A large group of these plants in flower shown up by a background of fine foliated trees and shrubs is a sight that would well repay the trouble of producing it. They thrive admirably in rich sandy loam, which should be well drained, as they dislike anything in the way of stagnant moisture. There are numerous stout and fleshy root fibres, disposed horizontally around a central crown, so that the operation of planting the roots has to be carefully performed, as they are very brittle. In planting, a hole should be made sufficiently large to allow of the root fibres being spread out straight in a horizontal direction, with the crown slightly higher, resting on a bed of sharp sand from 6 inches to 9 inches below the surface. Early autumn is the best time for taking up and replanting Eremuri, the sooner the better after the leaves have died down and the crowns

have been sufficiently ripened off. It is not advisable to take them up every year, for the less they are disturbed the better they like it. In a few years single plants will develop several crowns, each producing its raceme of flowers. As these would not be so large as those on a plant restricted to a single crown it is necessary to lift the plant and separate them. This may be easily done with care, as they pull apart readily.

Although perfectly hardy, the habit of the *Eremuri* in starting into growth early in the spring exposes them to the late spring frosts, from which they suffer much injury if not protected in some way. Dry ashes placed over the crowns answer the purpose to a certain extent, and sometimes inverted pots or hand-lights are used for covering during the night and removed in the daytime. Shrubs also form a great protection, but should not be so closely planted as to rob the plants of their nourishment. Of those in cultivation only about four species are generally grown in gardens; the others are only met with in botanical collections.

E. Bungei.—A charming plant, growing 4 feet to 5 feet high, with narrow and glaucous leaves and bright yellow flowers, closely set on a rather slender stem. Rather more tender than the other species, it requires a well-sheltered warm situation, where it will form handsome tufts and produce numerous flower-stems. It flowers in June and July. Persia.

E. himalaicus.—One of the hardiest and most useful species we have, with its long racemes of beautiful white flowers on stems which range from 4 feet to 8 feet high. It is rather later in starting into growth, and thus escapes many of the spring frosts. The flowers are densely packed and take up from 2 feet to 3 feet of the upper part of the stem. It is a native of the temperate Himalayas and flowers in May and June.

E. Olgae.—One of the latest in flower, this species has stems about 4 feet high, with rather lax racemes of handsome flowers. These vary in colour from rose to those of a very pale shade of yellow. It is a native of Turkestan, flowering in July.

E. robustus.—This may be called the most handsome species, with its robust stems often reaching to a height of upwards of 10 feet, the upper half being closely set with large rose-coloured flowers in May. It is one of the oldest species in cultivation, as well as being one of the easiest to manage. A native of Turkestan. *E. r.* var. *elwesianus* is a vigorous form with deeper-coloured flowers. The *Eremuri* are all easily raised from seed, although it takes several years to produce a flowering plant. They also cross readily, and to this fact we owe the existence of several lovely hybrids, the chief of which are:

E. him-rob (*himalaicus* × *robustus*), 8 feet high, with pale pink flowers.

E. Mrs. Reuthe (*turkestanicus* × *Bungei*), pale yellow.

E. Tubergeni (*himalaicus* × *Bungei*), pale yellow flowers on long racemes.

E. Warei.—A late-flowering plant, 4 feet to 6 feet high, with orange-salmon flowers. There is also a white variety of *E. robustus*.

These plants are all worthy of a prominent

place in the best gardens, and will not prove difficult to manage when carefully planted.

W. IRVING.

MICHAELMAS DAISIES.

THE perennial Asters or Starworts are particularly valuable in the autumn garden, since, by the aid of their different varieties, a blooming period of over three months is obtained, and their tender colour scheme affords a relief to the gorgeous scarlets, crimsons, and yellows of the Cactus Dahlias and perennial Sunflowers, while their tints range from the purest white, through soft lavender, to the richest purple, comprising also many forms in which the flowers are of a rosy or pink shade. Amongst the innumerable seedlings raised of late years there are many of high excellence, but no one except the possessor of an extensive garden can hope to grow a full collection, and, therefore, in almost every case, a selection of the best varieties has to be made.

I have found the following seventeen kinds fairly representative, although, doubtless, a change for the better might be made by the substitution of some of the newer varieties for certain of those

dwarf and compact growth, bearing larger blossoms than any of the family, but perfecting these at too late a date to render it a suitable plant for permanent culture in the open in cold districts. In such, however, it may be carefully lifted from the open ground and potted as the buds commence to show colour, when it will expand its flowers in the conservatory; height 2 feet 4 inches, flowers deep violet-blue with golden centre, nearly 2½ inches across.

A. lævigatus, a rather weak-growing form, something after the style of *A. acris*, but scarcely so ornamental, height 3 feet 2 inches, flowers rosy lavender, 1 inch across. *A. patens*, another weak-growing variety, height 3 feet, flowers lavender-blue, 1½ inches across. *A. Perry's Favourite*, a very valuable form, height 3 feet, flowers clear pale rose 2 inches across and very pretty. *A. Perry's Pink*, a much stronger grower than the last-named, height 3 feet 11 inches, flowers deep rose, nearly 1½ inches across. *A. puniceus pulcherrimus*, a noble form, growing to a height of 6 feet 8 inches, and bearing flowers of the faintest lavender, turning to white, crowded thickly on the shoots and 1½ inches across, one of the best for distant effect. *A. Purity*, height 6 feet, flowers white, just over 1 inch across. *A. Robert Parker*, a very handsome

GROUP OF EREMURUS ROBUSTUS IN THE GARDEN OF MR. H. J. VEITCH, EAST BURNHAM PARK, SLOUGH.

(From a photograph kindly sent by Mr. W. J. James, Woodside, Farnham Royal.)

named. In alphabetical order their names are: *A. acris*, a comparatively weak grower, height 3 feet 4 inches, flowers 1½ inches across, very starry in form, with narrow petals of a deep lavender-blue colour. *A. Amellus bessarabicus*, one of the best, especially adapted to small gardens, as it has not the spreading habit of so many of the more vigorous varieties, height 3 feet, flowers purple-blue, 2 inches across. *A. Arcturus*, an almost black-stemmed form growing to a height of 5 feet, bearing lavender-blue flowers 1 inch across. *A. cordifolius* Photograph, a pretty and graceful variety with arching, many-branched shoots 5 feet 4 inches in height, starred with countless small pale lavender flowers rather over half an inch across. *A. ericoides*, one of the best known and most popular of the Michaelmas Daisies, a dwarf plant, with Heath-like leaves, attaining a height of 2 feet 4 inches, and bearing pure white starry flowers half an inch across. *A. Esme*, a low-growing variety 2 feet 5 inches in height, with white flowers 1½ inches across. *A. grandiflorus*, a particularly handsome variety of

variety, 6 feet 9 inches in height, very graceful in growth, bearing pale lavender flowers nearly 2 inches across, which are borne far more sparingly on the many-branched shoots than in the case of *A. puniceus pulcherrimus*, but on that account more valuable for indoor decoration. White, unnamed seedling, an improvement on *Purity* in size and abundance of flowers, height 5 feet 5 inches, flowers 1½ inches across. *A. Tradescanti*, an exceedingly graceful plant, and one of the best for indoor decoration, attaining a height of 5 feet 2 inches, and bearing white starry flowers, with very narrow and widely divided petals about three-quarters of an inch across. The leaves are narrow and the flower-sprays have quite a feathery appearance. *A. vimineus*, another very pretty form, 4 feet 10 inches in height, bearing countless small white flowers barely half an inch across. The heights may not correspond with those attained in other gardens, but in each case the tallest shoot of the plant and the individual flower has been carefully measured. In order to assist amateurs in selection, I give the

dates when each variety was in perfection: A. Amellus bessarabicus, September 6, not entirely out of flower until October 20; A. Esme, September 7, a good companion for the last-named; A. patens, September 9; A. lavigatus, September 15; A. acris, September 16; A. Purity, September 18; A. Arcturus, September 22; A. Perry's Pink, September 24; A. Perry's Favourite, September 26; A. White seedling, September 28; A. puniceus pulcherrimus, September 30; A. Robert Parker, the same date: A. ericoides, October 1; A. cordifolius Photograph, October 5; A. vimineus, October 13; A. Tradescanti, October 30; A. grandiflorus, November 11. Of the varieties named, those most suited by their habit of growth for small gardens are A. Amellus bessarabicus, A. Esme, A. patens, A. lavigatus, A. acris, A. ericoides, and A. Perry's Favourite.

South Devon.

S. W. FITZHERBERT.

TREES AND SHRUBS.

THE HONEY LOCUST (GLEDITSCHIA TRIACANTHOS).

MANY of our deciduous trees show some of their prominent features more during the winter when devoid of foliage than at any other season, and among them must be included this *Gleditschia*. The formidable spines produce an effect totally dissimilar from any of its associates. In this the spines, many of which are as much as 3 inches in length, are produced in clusters, and borne not only on the young shoots, but also on the main trunk and principal branches of the tree. In an allied species *G. sinensis*, also known as *G. horrida*, the spines on the trunk of the tree even surpass those of *G. triacanthos*, but on the minor branches they are less noticeable. Of *G. sinensis* there is a weeping form. The Honey Locust forms a decidedly ornamental tree when furnished with foliage, for the pinnate leaves are of a beautiful light shining green, which, especially in its younger stages, is very noticeable. When larger it bears a certain resemblance to the False Acacia (*Robinia Pseud-acacia*), but as a rule it is more open. The leaves are late in appearing in spring, and in autumn, before falling, they usually change to a bright yellow colour. It is a very good tree for the neighbourhood of smoky towns, particularly if the soil is deep, and not dried up at any time. Unlike most members of the order Leguminosae, the flowers of the Honey Locust are not showy. It is a native of North America.

T.

TREES & SHRUBS WITH COLOURED FOLIAGE.

(Continued from page 363.)

ALNUS GLUTINOSA VAR. AUREA AND **A. INCANA VAR. AUREA** are both golden-leaved Alders, which are useful for planting in the vicinity of water. Their colour is best in spring and early summer.

ARALIA CHINENSIS VAR. ALBO-MARGINATA.—Of recent introductions this is one of the most striking, the leaves being as large and ornamental as those of the type, while in addition they are prettily variegated with silver. It should be given a prominent place and not cramped for room.

ARTEMISIA TRIDENTATA.—This is a relative of the well-known Southern-wood, from the Western United States. It is a somewhat rare shrub, growing 3 feet or so high, with small silvery, tridentate leaves. It is useful for a small bed, and forms a good silver patch in a mixed shrubbery.

ARUNDINARIA.—Although Bamboos are not prominent in this group, there are two which can be included—*A. auricoma*, a Japanese species, growing from 3 feet to 4 feet high, with golden variegated leaves, and *A. Fortunei*, likewise from Japan, growing 2 feet high, and having green and white variegated leaves.

ATRIPLAX.—*A. confertifolia*, a pretty, compact growing species from the Western United States, with small, silvery leaves, which, when first

starting into growth, have a rosy tinge, and *A. Halimus*, a tall growing plant, with silvery leaves, are worth growing.

AUCUBA.—The value of the *Aucuba* is well known, and it and its numerous varieties are invaluable for the garden, especially where ground under the shade of trees has to be covered.

BERBERIS VULGARIS VAR. FOLII PURPUREIS is a handsome and useful purple-leaved form of the common Barberry.

BUXUS.—Several varieties of the common Box (*Buxus sempervirens*) have variegated leaves, *B. s. argentea*, *aurea*, *maculata*, and *aureo-marginata* are of the best.

CASTANEA.—The common sweet Chestnut is represented by *C. sativa* var. *albo-marginata* with white variegated leaves, and *aureo-marginata*, in which case the variegation is yellow.

CATALPA.—*C. bignonioides* var. *aurea* is the best of the coloured leaved Catalpas. The leaves are of a deep yellow hue, and keep their colour well throughout the summer. It makes a handsome specimen plant, and stands out boldly in a mixed shrubbery.

CORNUS.—Among the Dogwoods there are several very useful variegated leaved shrubs. *C. alba* var. *sibirica* variegata has white variegated leaves. *C. a. var. Spæthii* is one of the best of all variegated foliaged plants, and should be found in every garden, for it is useful alike for shrubberies and specimen beds; for the latter work it is in fact one of the very best shrubs we have. The leaves are golden and green, the green being of two shades. The colour is good from the time the leaves appear until they fall, whether in full sun or partial shade the colour is the same. *C. macrophylla* variegata, or *C. brachypoda* variegata as it is sometimes called, is a rare and curious white variegated shrub, but it does not appear to be very hardy when young. *C. Mas. var. elegantissima* is a small leaved variegated form of the Cornelian Cherry, while another variety of the same thing with larger white variegated leaves is *C. Mas. variegata*.

CORYLUS.—Coloured leaved Nuts are represented by *C. Avellana* var. *aurea* and *C. maxima* var. *atropurpurea*, the former having golden leaves and the latter purple ones. The last named forms a good subject for a bed, as it can be kept dwarf by pruning and is always of good colour.

DEUTZIA.—*D. crenata* var. *punctata* and *D. gracilis* var. *variegata* have golden variegated leaves, but are not worth extended cultivation.

DIERVILLA.—*D. florida* var. *variegata* has golden variegated leaves, but is not of much value; *D. japonica* var. *Looymansii aurea*, however, is worth growing for its golden leaves, which are very pretty when young.

ELAAGNUS.—A number of species and varieties of *Elæagnus* make very handsome and useful shrubs for the purpose under notice. *E. argentea* has small silvery leaves. *E. macrophylla* has large leaves, white on the under surface and greyish above, while *E. glabra* and *E. pungens* have each varieties with handsome gold and silver variegated leaves. The varieties of *E. pungens* known as *aureo-picta*, *Simoni*, *Simoni aureo-variegata* and *tricolor* are specially worthy of note. All make large bushes 6 feet or 8 feet high, with a like diameter.

W. DALLIMORE.

(To be continued.)

THE ROSE GARDEN.

EXHIBITION ROSES—ANALYSIS 1897—1904.

TEAS AND NOISETTES.

IT is a very different note from that which Mr. Mawley was obliged to use last year, in dealing with this section that he now (see the *Journal of Horticulture*, November 3, 1904) refers to the Tea Roses exhibited at the Temple Gardens on July 6 last. Last year it was almost a tale of woe, this year it is almost a paean of triumph. Never I suppose in the history of the society's annual show has this section been more numerously represented than it was this year.

A glance at the third column of the analysis gives us the number of times each individual flower was found in the prize-winning boxes throughout the show. Last year the three leading Tea Roses in the analysis were Maman Cochet, Catherine Mermet, and White Maman Cochet, exhibited respectively in thirty-three, twenty-nine, and twenty-six winning stands; this year the three leaders were exhibited no less than seventy-five, fifty, and sixty-one times respectively, or rather more than twice as often, due not so much to any increase in the number of classes as to keener competition throughout.

TEAS AND NOISETTES.

(TABLE II.)

Position in Present Analysis.	Average Number of Times Shown, 1897—1904.	No. of Times Shown in 1904, at the N. K. S. Show, Temple Gardens.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	50.5	75	White Maman Cochet	1897	Cook	White, tinged lemon
2	49.0	50	Maman Cochet	1893	Cochet	Deep flesh, suffused light rose
3	47.0	61	Mrs. Edward Mawley	1899	A. Dickson and Sons	Pink, tinted carmine
4	35.4	32	The Bride	1885	May	White, tinged lemon
5	33.6	20	Catherine Mermet	1869	Guillot	Light rosy flesh
6	29.1	34	Comtesse de Nadaillac	1871	Guillot	Peach, shaded apricot
7	28.7	18	Souvenir de S. A. Prince	1889	Prince	Pure white
8	27.2	19	Mme. Cusin	1881	Guillot	Violet-rose
9	25.9	24	Innocente Pirola	1878	Mme. Ducher	Creamy white
10	25.5	31	Medea	1891	W. Paul and Son	Lemon yellow
11	25.3	26	Bridesmaid	1893	May	Bright pink
12	24.4	15	Mme. Hoste	1887	Guillot	Pale lemon yellow
13	24.0	25	Souvenir d'Elise Vardon	1854	Marest	Cream, tinted rose
14	23.2	28	Muriel Graham	1896	A. Dickson and Sons	Pale cream, flushed rose
15	23.0	8	Souvenir d'un Ami	1846	Belot-Defougère	Pale rose
16	20.0	20	Souvenir de Pierre Notting	1902	Sonperr et Notting	Apricot yellow, shaded orange
17	18.4	18	Mme. de Watteville	1883	Guillot	Cream, bordered rose
18	17.7	9	Maréchal Niel	1864	Pradel	Deep bright golden yellow
19	17.0	8	Cleopatra	1889	Bennett	Creamy flesh, shaded rose
20	13.7	13	Ernest Metz	1888	Guillot	Salmon, tinted rose
21	12.9	10	Marie Van Houtte	1871	Ducher	Lemon yellow, edged rose
22	12.6	7	Caroline Kuster	1872	Pernet	Lemon yellow
23	12.5	8	Hon. Edith Gifford	1882	Guillot	White, centre flesh
24	12.1	1	Anna Olivier	1872	Ducher	Pale bluff, flushed
25	11.7	14	Golden Gate	1892	Dingee and Conard	Creamy white, tinted rose
26	11.4	8	Princess of Wales	1882	Bennett	Rosy yellow
27	10.1	6	Niphetos	1844	Bougère	White
28	8.7	0	Robens	1859	Robert	White, shaded creamy rose
29	8.4	15	Ethel Brownlow	1887	A. Dickson and Sons	Rosy flesh, shaded yellow
30	7.0	7	Mme. Jules Gravereaux	1901	Sonperr et Notting	Flesh, shaded peach
31	5.7	3	Jean Ducher	1874	Mme. Ducher	Salmon yellow, shaded peach
32	5.4	2	Mme. Bravy	1848	Guillot	White, flushed pink

* New varieties whose positions are dependent on their records for the 1904 show only.

That grand Rose White Maman Cochet breaks all records with a total of seventy-five blooms. I have often referred to this sort as the finest Tea Rose in cultivation, and last year, when it had to be content with third place, I remember stating that in my opinion it was *facile princeps*. I have not had long to wait to see it occupy the place of honour. That other fine Tea Mrs. Ed. Mawley was to be found in no less than sixty-one prize stands, followed by Bessie Brown (fifty-four), Mildred Grant (fifty-three), and Maman Cochet (fifty); the sixth place is filled by Mrs. John Laing with a total of forty-five, so this year the Teas easily beat their cousins the Hybrid Perpetuals and Hybrid Teas. For the first time I think in these tables The Bride takes precedence over her parent Catherine Mermet, and I note that Comtesse de Nadaillac comes back with a rush. Last year with a total representation of eleven flowers only she nearly lost her place in the first half dozen, but this year, with an appearance in the boxes of successful exhibitors of rather more than three times as many, she makes sure of it again.

Medea, which found its way last year in a most extraordinary fashion into nearly every prize stand, and in consequence was the most frequently exhibited Rose in the whole exhibition, has, compared to former records, again done well, and is steadily creeping up the table. It is evidently one of those Roses, like Lady Moyra Beaulerc in the Hybrid Perpetual section, that is improving in constitution, instead of, as too many do, deteriorating, though perhaps the cases are hardly similar, as although Lady Moyra received a card of commendation in 1895, it was not put in commerce till six years afterwards, or ten years later than Medea.

It is interesting to notice while touching on this point of date of introduction that good Teas are evidently much scarcer than the Hybrid Teas or Hybrid Perpetuals, for while representatives of the "early forties" are still to be found in their table, if you take an equal number of the Hybrid Perpetuals (namely, the first thirty-two), we get into the sixties before we reach the earliest date. Another point worthy of notice is that, with the exception of seven, all the Teas are of foreign raising, while in the other table the first thirty-two are equally divided between home and foreign productions. Perhaps Messrs. Alexander Dickson will kindly note.

There are only two new Teas of recent introduction mentioned in the analysis, namely, Souvenir de Pierre Notting and Mme. Jules Gravereaux, both from Messrs. Soupert et Notting, the latter, although the older Rose, being the least known of the two. It is called, I presume, after one of the family of that well-known rosarian M. Gravereaux, who is reputed to have one of the finest collections of Roses extant. I have not yet grown the Rose, but I saw some plants of it at Colchester this autumn that looked very promising. Of Souvenir de Pierre Notting it is not necessary here to say much; it will, I think, find its way into the first dozen, but although it is called a yellow Maman Cochet, it is much thinner than either of the flowers bearing that name; it is wonderfully free flowering, makes an excellent standard and is a welcome addition to this, the most beautiful of all the various sections of the tribe Rosa.

The date of the show or earliness or lateness of the season can always be told by the place in the analysis of certain Roses. Anna Olivier is an excellent case in point. Last year Anna Olivier was to be found in no fewer than thirty-one stands, this year she made her appearance in one only; the non-appearance of her relation, that other beautiful new Tea Lady Roberts, in the table is thus accounted for. Rubens, a still earlier flower, was evidently all over, as not a single bloom of it was exhibited, whereas last year (1903) it was present in no fewer than twenty-two boxes.

I make these comparisons of the two years for the purpose of showing that it is exceedingly dangerous to take the record of one year only, and it is one of the features, and a great feature, in this analysis of Mr. Mawley's that we have combined in the tables the results of the last eight years, so that an early season is balanced by a late one, a late date for the exhibition by an early one, and the happy medium

or true average, as Mr. Mawley calls it, is arrived at, and this it is which no doubt has caused these tables to be recognised as such an excellent guide by all Rose growers for exhibition.

I have referred to the scarcity of new Teas. It is just possible that some of those new Roses sent out more for garden decoration than for exhibition may with high culture come good enough for the latter purpose. There are three that I have grown this year that strike me as likely to be worth trying—Mme. Jean Dupuy, Mme. Vermorel, and Général Gallieni. The first was sent out in 1902 by P. Lambert, and is a pale flesh and yellow, with the edges of its petals distinctly bordered with rose, after the style of the old Homere, and is remarkably free flowering. It has been exhibited frequently during the year, a very fine bunch of it forming the centre of Messrs. Frank Cant's first prize stand for garden Roses at the autumn show of the National Rose Society, where it was much admired. Mme. Vermorel is a mixture of yellow and buff quite distinct, a good grower, making a fine standard, and which has given me many fine flowers this autumn. Général Gallieni is the oldest Rose of the three, but one that does not seem to have found its way into most of the catalogues or yet into general cultivation. When good it is very fine, but the flowers if not disbudded are on the small side; its colour is not easy to describe, outside of petal bright cerise, inside reminiscent of Maman Cochet, deepening towards base of petal to copper. It is one of the Nabonnand Roses, all of which I know make better bedders than they do exhibition flowers, still I have had some good blooms, and I am sure it is worth trying. The remaining tables of Mr. Mawley's interesting analysis I will deal with later.

Brantwood, Balham, S.W. H. E. MOLYNEUX.

HINTS FOR THE PRESENT SEASON.

(Continued from page 249.)

SINGLE PLANTS ON LAWNS OR IN BORDERS.

PREVIOUS to planting Roses singly on lawns or in borders a hole should be dug for each, 18 inches square and 18 inches deep. The soil removed from the holes should be well mixed with one-fourth of its quantity of well-decayed manure before being restored to them. If the soil be found poor and unsuitable, better soil from another part of the garden or some turfy loam should be substituted. No grass should be allowed to grow within at least 6 inches of the stems of Standard Roses planted on lawns.

CLIMBING OR PILLAR ROSES.

For climbing and other Roses of very vigorous growth the hole prepared for their reception should be 2 feet square and 2 feet deep, and care be taken that the soil be of a suitable character and well enriched with manure. For it must be borne in mind that such Roses require much more root room than those which are pruned back every year, and in most cases are intended to occupy the same positions for many years to come. Therefore, any extra care and attention bestowed on the planting of strong-growing Roses like those referred to will, sooner or later, be well repaid.

STAKING STANDARD ROSES.

As the planting proceeds each plant should be secured to a firm stake of some kind. In order to avoid damaging any of the roots the stakes should be driven firmly into the holes prepared for the reception of the plants before planting them. Dwarf or bush plants do not need staking, but, to prevent injury from high winds, all long growths should be shortened previous to planting.

THE LABELLING OF ROSES.

Where there is only one plant of any variety a permanent label with the name of the Rose either written or printed upon it should be attached to a small stake placed near it, and not to any part of the plant itself; but when several plants of the same variety are grouped together, or follow one another, labels will only be necessary at the beginning of each such group or row.

WINTER PROTECTION OF DWARF TEAS AND NOISETTES.

All kinds of Roses should be planted in the way previously described. Teas and Noisettes and

other tender sorts, however, require, after planting, some protection to be given them, or they will be liable to injury should an unusually severe frost afterwards set in. Fortunately, dwarf plants may be readily protected by drawing the soil over the centre or crown of them to the height of 3 inches or 4 inches. This will be found an excellent method, for, except in extreme cases, the plants are in this way saved from serious damage, although the exposed portion of their shoots may be destroyed. If further protection be required, Bracken or straw may be placed loosely among them.

WINTER PROTECTION OF STANDARD TEAS AND NOISETTES.

In most winters the insertion of Bracken in the heads of Standard Roses, or tying their shoots to a secure central stake and thatching them with straw or Bracken, will be found to answer excellently.

THE AURICULA IN DECEMBER.

AT this season of the year very little can be said on the work which can be done amongst Auriculas; they are at rest. Pick off decayed leaves, and give plenty of air by night and day. Frost at this time of the year will do no injury. It may not be out of place at this "dead" season to talk of the important points of soil and potting, on which subjects opinions greatly vary.

As regards the proper soil in which to grow Auriculas, no "royal road" can be pointed out, nor an infallible compost recommended in which alone they will thrive. Each grower has plans more or less of his own. One thing, however, is pretty freely acknowledged, and that is the mysterious compounds we read of as being used by our forefathers are discarded for ever. Simple and easy methods appear to be quite successful. In the first place a supply of yellow turfy loam must be obtained and laid up for six months or more, turf side downwards, with a small quantity of half-rotten stable manure between each layer. In preparing the soil for the potting bench do not break it up too fine. If some of the turves are not sufficiently decayed cut into strips with a long knife (an old table knife), and break with the fingers into pieces the size of Walnuts. Do not use soil which has been passed through a sieve. Take two-thirds from the heap of soil above described, and add to it one-third in equal parts of rotten manure and leaf-mould. When taken to the potting bench for use silver sand or crushed oyster-shells should be added in suitable quantity to keep the soil open. The early autumn would be a good time to lay up the soil for use the following spring and summer.

The time for repotting is an open question. Some advocate just after the blooming season, others a later date. My experience is that the state of growth of the plant must determine this. Strong-growing plants which have filled their pots with roots can be potted early; but in the case of a delicate grower which has not made much root action it will be better to defer the operation till early in August. More or less of the underground stem may be found decaying. It must be cut back, leaving a sound part with the freshest and youngest fibres to keep the plant in perpetual growth, but how far each stem may be shortened must be left to observation and experience.

Good drainage is an absolute necessity. Cover the hole in the pot with a piece of curved crock with the arch of it upwards, and about 2 inches of smaller pieces above it, then some turfy fibre or coarse Cocoanut fibre, then some of the rough pieces of potting soil. This will prevent any of the fine mould getting to

the crocks and spoiling the drainage. Be careful not to overpot any plant, and, above all, pot firmly and deep enough, so that no naked stem be above the soil. The plant should be in the soil quite up to the first leaves, and the roots must be thoroughly examined, decayed ones removed, and also any *Auricula aphid* washed or brushed away. Great care must be taken in removing decayed leaves and stalks of autumn blooms. The latter must not be pulled out until they come freely from the socket. Should any traces of decay appear it can be arrested by the application of powdered quicklime.

Bishop's Stortford. WILLIAM SMITH.

LATE PLANTING OF DAFFODILS.

OF course the early autumn is the best time for planting Daffodils, but it is not too late even in January. I know this from experience. Last January I planted 4 cwt. of bulbs, *Horsfieldi*, *Johnstoni*, *Queen of Spain*, *Emperor*, *poeticus ornatus*, and *Leedsii*, and very few failed. The display was delightfully fresh and quite unexpected. The grouping of Daffodils shown in the illustration is very effective, but the bulbs were put in during October. NARCISSUS.

ROUND ABOUT A GARDEN.

SUBURBAN GARDENS.

I HAVE seen a lot of suburban gardens lately, among which a violent epidemic of "doing up" seemed to be raging; and it was very interesting to see how one good garden always makes many. There are some streets with only the dingiest, most miserable gardens down the whole length

of both sides of the way; and there are others, with precisely similar houses, in which every garden on both sides is a pattern of neat and effective use of a small space for purposes of display. And there are yet other streets where most of the gardens are indifferent, with the exception of a group of three or four, perhaps, in the middle and one or two in other places. It is all a matter of neighbourly rivalry. It may be that in the whole of a long street, whose houses are tenanted by hard-working City men, living to the margin of their incomes and finding their pleasures in other things than gardening, no one has shown his neighbours what can be done with a small strip of ground between iron railings. So all the gardens gradually sink to the same level, with some gapped Box edging, a grimy Laurel bush or Holly tree, a few clumps of *Chrysanthemums*, perhaps, and a lot of gravel.

CONTAGIOUS HORTICULTURE.

Presently, however, to such a street will come a new tenant, whom surprised neighbours will observe at times discussing garden politics with the local nurseryman. During the winter they will note the contrast between the extreme neatness of the newcomer's flowerbeds and the green vitality of its new evergreens contrasted with the griminess of their own sparrow-haunted Lilac bush or Holly tree. It is his "fad," they say, as they hurry by to catch their train to town. But the first real shock comes in spring, when the newcomer's garden suddenly bursts into a conflagration of *Crocuses*, with *Tulips*, *Hyacinths*, and *Narcissi* to follow. From either end of the street the new garden shines "like a jewel in an *Ethiopian's* ear." The men, who have to pay the gardener, and except on Sundays only catch passing glimpses of their front gardens in the morning and evening, might be still content to

say that this was their neighbour's "fad," and leave it at that. But almost every villa contains at least one woman of the family; and the beauty of the neighbour's garden, contrasted with the squalor of her own, stirs her soul. So the local nurseryman prospers as the street breaks out into spots and blotches of colour, until by late summer it is in eruption of *Geraniums* and *Calceolarias* from end to end. So quickly, too, do local traditions take root that in a certain row of villas in a Thames-side suburb, where a single resident clings conservatively to the Lilac-bush-and-gravel style of garden, all the neighbouring children firmly believe that he murdered his wife twenty years ago and dare not have the garden dug up for fear her bones should be found. And only a quarter of twenty years ago all the gardens were as bad as his!

GARDENS ALL ALIKE.

Next to this epidemic contagion of gardening the feature which most attracts the attention of a wanderer in suburbs is the amazing sameness of type in villa gardens. In spite of the thousands of beautiful and hardy plants which are available you may go down street after street of "villa residences" and find that collectively there are more gardens than there are kinds of plants grown in them, the same few familiar sorts being shuffled and reshuffled in endless monotony. This is partly due, no doubt, to lack of knowledge on the part of residents, but chiefly to the limited stock of the local nurseryman. All his clients know *Geranium*, *Lobelia*, *Calceolaria*, and *Marguerite* by name and sight, and if they are satisfied why should he tempt them to stray outside the beaten path of common demand and easy supply?

LOCAL EXCELLENCE.

But not all suburbs are alike. As you can trace the effect of a single well-kept garden in brightening up a whole row, so, in a more diffusive way, you may detect the influence of neighbouring public gardens upon a whole locality. In the suburbs round Hampton Court, for instance, evident knowledge is displayed in cottage gardens of the fact that surplus bedding plants are distributed to the public gratis, while at Kew many small gardens are peculiar for the unusual and rare character of the plants which they contain. It needs no clairvoyance to guess that the high brick wall which runs down the other side of the road encloses a botanic garden. Ealing, again, is the type of another suburb where there is great variety in the kinds of plants grown in the villa gardens, although after a time you find that the variety can be classed in patches. This comes, I take it, from the fact that Ealing is essentially a suburb for leisured folk—retired Anglo-Indians and the like—who all have time to consider their gardens, and thus give

GROUPING OF DAFFODILS UNDER OLD TREES.

employment to rival nurserymen, who compete against each other in the variety and novelty of the horticultural goods which they supply. The result, however, is distinctly pleasing.

E. K. R.

NEW AND RARE PLANTS.

CAPSICUM ANNUUM VAR. CONOIDES.

THIS is a very showy plant, a variety of the common *Capsicum*, bearing a large number of reddish fruits displayed to the best advantage. It grows some 2 feet high, and develops some 2 feet across. The common *Capsicum* is not a plant to be despised for home decoration, and it makes an attractive group in the greenhouse when well fruited, therefore this new one will be welcomed. Plants in fruit are quite an agreeable change from plants in flower, and they have, too, a distinctive beauty. This new variety was exhibited by Gurney Fowler, Esq., Glebelands, South Woodford, before the Royal Horticultural Society on the 15th ult., and received an award of merit.

COLOUR IN THE BORDER.—VII.

WE now come to sections 10, 11, and 12, and when we have dealt with these the colour scheme we have proposed for the mixed border is virtually completed. In section No. 10 white is again repeated, and by now, I fancy, our readers will have discovered several valuable additions overlooked by me; they, too, are by far the best judges of what plants to employ and what to avoid, for I cannot possibly dictate to them more than I have done already the course they are to pursue, knowing neither the wealth nor length of the borders, soil, position, or climate—all factors of the greatest importance in the choice of material. I, all through this series of articles, have been working in the dark in these respects, and have only humbly suggested some possible combinations.

Many of the plants mentioned I am growing myself, and I find them extremely valuable if kept in proper order. The soil in my garden is very fertile, and things increase rapidly. All the strong-growing herbaceous plants, like the *Achilleas* and *Galegas*, must be kept in check and properly staked, and if this is done there is no reason why they should not be employed in a border only 7 feet wide. I do not think, however, that I have advised the use of *Galegas* in the colour scheme. I did not mention the beautiful *Romneya Coulteri* or white bush Poppy, which would be charming among your white flowers, because it is

undoubtedly delicate, and wants a warm, peaty soil. It really does best in a southern aspect protected by a wall. Then it is very fine, growing 6 feet or 7 feet high, and producing a dozen of its beautiful transparent white flowers at once, from the end of June to the beginning of October. You will see by this, too, that the *Romneya Coulteri* is rather large for a 7-foot or 8-foot border. My experience of the medium-sized gardens, say, of three acres all told, is that borders cannot be allowed more space, at the most 9 feet or 10 feet. Of course, I am allowing that for plants. Any shrubs planted as a hedge must not be allowed to trench on the ground set apart for smaller subjects.

Well, we will suppose that the white section No. 10 and the blue section No. 11 are both

advantage, and are fairly hardy in the South and Midlands, but they really succeed best on the south and west coasts. Cut them down when their flowering time is over, and cover with coal ashes. The *Potentillas Louise van Houtte* and *Elizabeth* are a fine red, but there are others besides these to select from. The *Geums* are mostly too scarlet, but the red *Avens* (*Geum sylvaticum*) might do. Do not be afraid of planting *Heuchera sanguinea*, which, as Mr. Robinson says, is the most beautiful of all the *Heucheras*. Some people find it disappointing, but if it is properly handled it is all right. There are many plants that want humouring, and *Heuchera sanguinea* is one. If it declines to flower the second year take it up in July, cutting pretty close round it with a sharp spade, and put it into a corner

CAPSICUM ANNUUM VAR. CONOIDES.

finished according to the taste and fancy of the gardener, and we will pass on to red, which must now be used in contradistinction to scarlet, employed in section No. 2. I am afraid we shall find that red flowers are scarce, and this is one of the things that makes the difficulty of colour bedding so complicated. You can only have for your background Dahlias for the autumn, and there are some fine *Phloxes*, *Hollyhocks* for the late summer, and early-sown Sweet Peas, treated as before suggested, *Coccinea* and *Splendour* being very good tints. The deep red Oriental Poppy will come next. These Oriental Poppies must not be allowed to grow too large, and must be carefully staked, but of this more anon. Again, we have some red *Phloxes* from 2 feet to 3 feet high, *Torpilleur* being one. *Fuchsia coccinea* and *F. globosa* may be grown with

for a bit, and replace it in the autumn, when it will probably bloom better than ever.

A correspondent in THE GARDEN of the 5th ult. criticised one of this series of articles, and recommends *H. brizoides gracillima* instead of *H. sanguinea*. I do not know the variety, but it may be worth trying. This correspondent also recommends *Arundo Donax versicolor* instead of the old-fashioned Ribbon Grass. No doubt it is far handsomer, but I have always understood it to be only half-hardy. In the Berkshire valley, where lie my own borders, the early and late frosts are so destructive I dare not employ too many delicate subjects. The same reason holds good against planting *Ostrowskia magnifica*. As far as possible I use only hardy plants, reserving the more fragile ones for the snug sheltered corners. But to continue the list of red

flowers we must have Cannas (and some have red foliage), Peonies (*P. rubra* and the little *P. tenuifolia*, besides many others), *Chelone barbata* (for late summer and autumn), and *Centaurea montana rubra*. Among the *Salvias*, so excellent for autumn flowering, there are two red varieties, *Salvia pratensis rubra* and a pretty dwarf sort called *Salvia porphyranthera*. These, however, are delicate, and require lifting at the first sign of frost, and housing for the winter. Then there is *Pyrethrum roseum* and *P. roseum plenum*; a dark crimson *Lychnis* (*Flos-cuculi*), which is really a Ragged Robin, quite a pretty border plant. There are fine blood-red *Antirrhinums*, hardy *Chrysanthemums*, though the deep red tone is scarce, *Sweet Williams* for the choosing, and, for Carnations, several fine red border varieties, but why look further than the delightful real old Clove. *Anemones* of every shade can be had, and the double velvet *Primroses* which grow so well in "John Bull's other Island," besides the hybrid single varieties, *Tulips*, and, for the foreground, *Hepaticas*, single and double, and quilled *Daisies*.

AUGUSTA DE LACY LACY.
(To be continued.)

GARDENING OF THE WEEK.

FLOWER GARDEN.

ROSE STOCKS.

FOR bush Roses the Manetti is the stock most used. It produces a quantity of fibrous roots, and where the soil is light Roses budded on it are more likely to thrive than when grown on the Briar. The Manetti is increased by cuttings. For standard Roses the Briar is used, and the present is a good time to collect them. The wild Briar varies greatly in growth, and it is those which have smooth skins and but few prickles that are the best. It is not wise to keep them out of the ground longer than is necessary or the roots will shrivel. After trimming the roots and reducing the tops the Briars should be planted in deep rich soil, allowing 18 inches from plant to plant, and 3 feet to 4 feet between the rows. Plant firmly, and apply a mulching over the roots.

FALLEN LEAVES, &c.

Now that the leaves have all fallen a general clearing up should be made. The necessary quantity for hot-beds and leaf-soil should be carted to their respective places. The fronts of the shrubberies must be raked clear, but at the back and where they are not unsightly, and there is no danger of their blowing about, the leaves should be allowed to remain; they will gradually decay and feed the shrubs. All fallen or wind-blown leaves should be removed from the rockery, or as they decay there is the danger of rotting the smaller-growing plants.

While the weather continues mild any planting of trees and shrubs may still be done; but at this time of the year a mulching is more necessary than when the planting was done early in the autumn. Should hard weather set in rabbits sometimes gnaw and eat plants which are usually considered to be rabbit-proof, and it is often worth while to stretch a piece of wire-netting around any choice shrubs as a temporary protection. Michaelmas Daisies are amongst the herbaceous plants which pay for annual replanting, and, weather permitting, this may still be done, selecting the outer growths for that purpose.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

LILIES OF THE VALLEY.

UP to the present time the supply of these flowers has been kept up by forcing retarded crowns, but as the season advances, and the flowers from natural crowns are of a much better quality, a

batch of the latter should at once be placed in heat. It is not difficult to have them in by Christmas, as in nineteen to twenty-one days the flowers should be ready for cutting. Pots are best in which to force the earlier batches, the 4½-inch accommodating fifteen to eighteen crowns. The roots of the Lily crowns should be made firm among soil of a sandy nature, and at no time should this be allowed to become dry or the crowns will shrivel and fail to start into growth. Plunge the pots their full depth in boxes containing Cocoanut fibre, sifted leaf-soil, or stable manure, and place them on the hot-water pipes, where a temperature of 75° to 80° can be maintained. Finally the crowns should be covered lightly over with Moss, which must be kept moist. Seldom does the foliage accompany the flowers of the earliest forced batches; but with care this can be accomplished if proper attention to removing the crowns from the plunging material be given, afterwards placing them on a shelf near the glass immediately the flower-buds are discernible. Finally, the flowers are larger and last better when they open in an atmosphere that is kept buoyant by the judicious admission of fresh air.

LILACS IN POTS.

The earliest batch of these has just been put in a house the temperature of which does not for a few days range higher than 45° to 50°. In such a position the hardened stems of the plants, as well as the flower-buds, will develop. Before they burst into flower the plants require a temperature of 55° to 60°, with a little air to encourage the flowers to open freely and satisfactorily.

FORCING PLANTS GENERALLY.

To Roses that are just bursting into growth afford a little sulphate of ammonia in a liquid state, prepared at the rate of one tablespoonful of the sulphate to a gallon of water; one or not more than two doses from start to finish will be quite enough. Green-fly, with which the young growth at this time is frequently attacked, must be kept in check by occasionally fumigating with XL, and dust lightly sometimes the growth with flowers of sulphur to keep down mildew. Admit air judiciously. Sheep and cow manure, liquid, in a diluted form should be given to the roots of *Arum Lilies*, and their leaf-stalks prevented from becoming drawn and weak by the careful admission of air. *Freessias*, to keep them dwarf, must also be given a position near the glass. The flower-buds of the lovely pink-flowered *Prunus triloba* frequently go blind from no other cause than placing the plants in a high temperature at the start; but if treated as recommended for Lilacs, they seldom fail to flower satisfactorily.

ZONAL PELARGONIUMS.

The atmosphere of the structure in which these plants are flowering can, by affording fire-heat with air, be kept dry and buoyant, and a temperature of 50° or 55° be maintained. One thing essential to the health of the plants is care in giving water to their roots. Stimulants are scarcely necessary; highly diluted guano and soot-water are the best.

J. P. LEADBETTER.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

PINES.

THE fruiting Pines should have a night temperature of 68° to 70°, according to the weather. Cover the pits at night with mats or other material, as by this means it is more easy to maintain the requisite temperature, and it reduces the necessity of hard firing. Keep the bottom-heat steady at 85° to 90°, and carefully examine the plants once a week to see if they require water. When the fruits are half coloured no more water will be necessary until they are cut. Sprinkling the surface of the beds and damping the paths will supply sufficient moisture at this season of the year. If the plunging material near the hot-water pipes is dry thoroughly moisten it.

EARLIEST QUEEN PINES.

Those plants intended for starting early next month have been resting. The plunging material

near the pipes should be moistened rather than water the plants for a few weeks to come. The pits they are intended to occupy should be well washed and cleaned, and the plunging material prepared for their reception. Select those plants thickest at the base of the stem and having open centres; they are the most likely to show fruit before making fresh growth. Remove a few of the short leaves at the base and a little of the loose surface soil, and top-dress with good fibrous loam, adding a little bone-meal and soot. Make it firm. As soon as the temperature of the plunging material has decreased to 85° or 90° put in the plants about 2 feet apart. Do not allow the bottom-heat to exceed the latter figure. Give the plants a good soaking of tepid water when starting, and keep the house fairly moist. A night temperature of 65° is high enough to commence.

SUCCESSION PINES.

These should be kept quiet some time yet. Carefully examine plants that are in small pots, and plunge near the hot-water pipes, and water if necessary. Ventilate on all favourable occasions to prevent a soft growth.

FIGS.

If the early trees are expected to supply ripe fruits in April, no time should be lost in plunging them in a light position in a good depth of fermenting material. Syringe them daily about midday with tepid water. A night temperature of 50°, with a rise of 5° to 10° during the day, will be high enough. All permanent trees in succession houses should be pruned, cleaned, and got in readiness for starting, the borders top-dressed with good loam, wood ashes, mortar rubble, and bone-meal, and made firm. A moist atmosphere is necessary to start the trees, and as they require plenty of water good drainage is essential.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

MANURE HEAPS.

THE preparation of manure is at this period a most important work, and should be carried out without delay. Few gardens have too much cropping space, and where several crops are produced each season the land must be liberally dealt with. For most gardens where the soil is not heavy good farmyard manure is the best. On very heavy and clayey soils this should be lightened by incorporating leaves and stable litter. If the supply can be got ready and prepared in the manure court so much the better. It is advantageous to turn over a full supply at once, making it into a large heap, the larger the heap and the more firmly it is packed together the better it will be. If the manure is light it should be frequently turned and damped. Along with the supply all garden refuse that will decay may be mixed, except weeds that have run to seed. The supply should be allowed to lie for several weeks until it is well decayed, but frequent turning will always improve it.

PREPARATION OF THE SOIL.

A plan should now be formed for the various crops for another year, and the ground prepared accordingly. Land for Onions should be selected as soon as possible. Choose a good position. Wood ashes and soot may be placed on the plot as they are procured, and a plentiful supply of good manure that has been in preparation for some time. This plot should be trenched two spits and left in a rough state until early spring. Plots for Carrots should also be prepared. Fresh manure should not be added to the soil for this crop. Sand and wood ashes do much for this troublesome crop. Plots for Peas should be prepared with no niggardly hand. Land for early Potatoes should not be heavily manured. Should there be any alterations necessary in the garden, this is the most convenient season for carrying them out. The weather is also most suitable for all outdoor work. Walks may be repaired and gravelled, edging may still be relaid or mended, and many other things done now that there is no spare time for during the earlier months of the year.

GENERAL REMARKS.

In bad weather inspect stock of Pea and other stakes, and if possible add some new ones to the supply, sorting them into two or three sizes. All tree and other labels should be inspected and rewritten if required. Lights should be placed over Parsley in the open should severe frost set in. Attend to the regular sowing of Mustard and Cress and saladings of various sorts. THOMAS HAY.

Hoptoun House Gardens, South Queensferry.

THE FRUIT GARDEN.

ON KEEPING GRAPES.

IT is well known that some kinds of Grapes keep after they ripen much better than others, and no one who is desirous of keeping Grapes until fairly late in the new year would think of planting varieties for the purpose that are known to be bad keepers.

When, however, the best keepers, such, for example, as Lady Downes' Seedling, Appley Towers,

To this end vines for affording a late supply of fruit should be started into growth early enough in the season for their fruit to ripen by the end of September, and be grown under the influence of sufficient artificial warmth to maintain a warm buoyant atmosphere, this being especially important during the colouring period. Another necessary matter is to maintain the foliage healthy, for the fruit cannot possibly be supplied with its essential keeping properties without the aid of perfect foliage.

The manner in which the fruit sets has a marked bearing upon its powers of keeping, and pains should be taken during the flowering season to promote a circulation of warm fairly dry air through the house, in order to assist the flowers to fulfil their functions. Imperfectly fertilised berries are seedless and readily shrivel after they ripen; moreover, they do not fully develop. The thinning of the fruit has an important bearing on this matter. It should be executed in such a way as will ensure the perfect development of the berries without their being crowded.

After the fruit of some varieties is ripe—that of Black Hamburgh, for example—it soon loses colour,

more especially if high temperatures are maintained or it is unduly exposed to sunlight. The former evil can be guarded against by the discreet use of the ventilators and the heating apparatus, while the evil effects of powerful sunshine can be subdued by the use of light shadings, without detriment to the wood of the vines. This means may likewise be taken to prevent the ripe fruit of Muscat of Alexandria, &c., from being discoloured through bright sunshine. Only sufficient artificial warmth, when the fruit is ripe, should be employed to prevent the temperature falling below 45°. During foggy or wet weather the ventilators should be closed; but as soon as the atmosphere has cleared sufficient ventilation should be afforded to dispel, with the aid of the heating apparatus, any moisture that has gathered in the house. The bunches of Grapes should be frequently examined, and any decaying berries removed.

Even the latest varieties should be gathered and bottled not later than early in January.

Most Grape-growing establishments have a room of some kind for this purpose, provided with racks for the reception of the bottles. It need not be an elaborate construction; ours is placed over a packing-shed. It is lathed and plastered, and has a centre path with the racks on either side. A hot-water pipe runs round it upon the floor, and windows, which act also as ventilators, are placed at each end. It should be mentioned, however, that windows should be provided with blinds, as fruit keeps best in the dark.

In bottling Grapes it is advisable to use clear bottles, so that it can be readily seen if the base of the wood is submerged, and each bottle should contain a few pieces of charcoal, which has a purifying effect upon the water. Fill the bottles with soft water, and secure them in position before commencing to gather the fruit. Carefully cut the Grapes with all the wood that can be spared; remove the joints if too large to go in the bottle; carry each bunch direct to the room, without putting it down at all; and in placing the bunches

in position be certain that the wood reaches the water. Subsequently they should be frequently examined, and the water renewed when necessary, care being taken not to spill any. Decaying berries should be removed. When the external atmosphere is dry open the ventilators sufficiently to promote a slight circulation of air, keeping the temperature of the room regularly at about 45°. In damp weather the pipes should be slightly warmed, but in no case sufficiently to create a high temperature or very dry atmosphere, for this would do mischief by causing the berries to shrivel. T. COOMBER.

The Hendre Gardens, Monmouth.

PEAR KING EDWARD.

This is a useful Pear for cooking at this season. The fruits, as regards size and appearance, resemble those of Uvedale's St. Germain, but not the flesh. They are a little longer, pyriform in shape, and the skin is a dark green, much bronzed on the sunny side, and covered with russet spots. It is a handsome variety, and by some is relished for dessert, but as it ripens in October and November there are much better dessert sorts, so that I think it is more valuable for use when cooked. As it crops well it is fit for use some time in advance of the ordinary cooking varieties. I do not advise its culture for dessert; though the fruits are melting, there is a grittiness at the core which is not palatable; the flesh is sweet. When cooked it is excellent. The tree grows freely, and does well as a large bush or pyramid. The crop on standard trees gets much damaged by heavy winds owing to their size. It is an earlier variety than Gillogil, and, like the last named, a great favourite in the northern part of the country. I have seen this Pear very fine on a west wall in Scotland. G. WYTHES.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

QUALITY IN POTATOES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Mr. A. D. Hall of Rothamsted, the chairman of the National Potato Society's committee, having had all the returns from some twenty trial centres in diverse parts of the kingdom sent to him for collation, and seeing how different are the constituents of the soils or their mechanical conformation in which grown as furnished in these returns, has requested that 10lb. of the well-known Potato Up-to-Date grown at all these centres be sent to Rothamsted. A full scientific enquiry will be made in each case into the composition of each sample of tubers with a view to discover if possible what description of soil produces the highest quality. Possibly an analysis of each soil may have to follow. Quality in a Potato means not only starch development or flouriness, but also flavour. The statement of this fact may to some extent show that the Potato Society is not asleep. A. DEAN.

A FAVOURITE WINTER FLOWER.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Winter, with its accompaniment of frost and snow, cold wind and rain, is upon us, and we must perforce turn our attention from plants without to plants within. Even the Chrysanthemum, the last of all hardy flowers to bid farewell, has gone under during the recent wintry spell, and the first Christmas Rose has not yet dared to unfold its flowers, so the greenhouse is in favour. Probably the Chrysanthemum is really the most useful indoor flower at this time of year, but those who have them in quantity out of doors will rather have others under glass. Then it would be difficult to have anything more charming than the Freesia. It is not my intention now to give in detail the culture of the Freesia, for that would not be of much use at a season when it ought almost to be in

FREESIAS GROWN FOR MARKET IN THE CHANNEL ISLES.

or Alicante are grown, it taxes the skill of their cultivator to keep them in good condition as long as is necessary. It is equally important to some to keep such comparatively bad keepers as Black Hamburgh and Madresfield Court as long as possible, as it is to others to keep the later varieties, and it has occurred to me that some notes upon this subject might be of interest at this season, at least to inexperienced growers.

One of the necessary conditions is to have suitably constructed houses, the following points being all important—proper ventilation and heating, efficient glazing, and an open situation. A dry atmosphere must be maintained; drip and a damp sluggish air are fatal to Grape storage. There are other things, however, of equal importance as good vineries, and chief among them is the proper cultivation of the fruit. Grapes will not keep satisfactorily unless they are thoroughly well grown, and it is especially important that they be well ripened and contain a proper amount of saccharine matter.

flower; for the Freesia is essentially a flower for the winter. You may have it before Christmas, at Christmas, and after Christmas, by starting the bulbs into growth at intervals from June. I should like to say that it is not much use trying to force the Freesia into flower. The only thing to do if you want to have early bloom is to have them early

EUPATORIUM WEINMANNIANUM OUT OF DOORS.

in growth. They certainly can be hastened a little after the flower-stalks appear, but even then it is unwise to place them in a hot house.

The accompanying illustration gives some idea of the quantities of Freesias that are grown for export in the Channel Islands. From December to April this delightful flower is sent over in quantities, and finds a ready sale in the home markets. Planting is commenced in summer for the earliest gathering, and, in order to provide a continued supply, is repeated at intervals. The price fluctuates according to the season; it starts at 2s. 6d. per dozen bunches, but drops to 1s. when spring draws near. One firm ships about 2,000 dozen bunches per week on the average, and the result is said to be very satisfactory. The Freesia industry gives employment to a good many girls, who pick, bunch, and pack for market. White flowers are none too plentiful at Christmas, so that the Freesia should not be overlooked. Any one with even a cold greenhouse can grow it, provided frost is kept out by covering with mats on cold nights. An excellent plan where quantities are wanted is to place the bulbs in boxes instead of pots. If grown in pots, however, they are useful for home decoration as pot plants. Freesias should be carefully tied and staked, otherwise half their attractiveness is lost. Y. Z.

LILIUM SPECIOSUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In a recent issue Mr. S. G. Reid asks those who have been able to establish *Lilium speciosum* to relate their experiences. In this garden they grow without any difficulty. When I came here two and a-half years ago I found a large number of the white variety, and in course of remaking the garden they have all been moved. This summer those in a hot south border were rather dried up and did not flower so well as usual, but the majority in a west border were lovely. I have taken no trouble with them, and I suppose the soil suits them. It is very light and sandy, and the subsoil, which is only one spit below the surface, is sea sand. In the beds I get a depth of about 2½ feet of good soil made. I heard the other day of some *L. auratum* that established themselves in soil very like this. They were bought at

a sale at the end of April and planted among shrubs, and not only grew but multiplied.

C. V. NORMAN.

The Grange, Chelmondiston, Ipswich.

EUPATORIUM WEINMANNIANUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Having seen an article in THE GARDEN of the 5th ult. by Mr. Fitzherbert on *Eupatorium weinmannianum* as an outdoor shrub, I thought it might interest the readers to see a photograph of a plant in my garden. It has been growing there for years without any special care; the garden is an exposed one, too. I am also sending a box with some blooms from the shrub, which, if the weather is not too wet and frosty, will go on flowering through December. The photograph is of the largest of five plants all in bloom now.

MISS RICHARDSON.

Crown Hill, R.S.O., Devon.

[A very attractive outdoor shrub for so late in the year. The flowering shoots sent were as fresh as though they had been grown in a greenhouse. The pink-white flowers are not showy individually, but are profusely produced.]

CORNISH APPLES.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The illustration of Apple Cornish Aromatic (some seventy years ago known as Aromatic Pippin)—in season from November to February—should help to get it and its county compeer Cornish Gilliflower correctly named. A really beautiful example of the latter variety from Weybridge was recently shown at Kingston as Cornish Aromatic, and it is probable that the confusion of names is common. So many fruits are found incorrectly named in gardens, because sent out from nurseries under wrong names. But both Cornish Aromatic and the Gilliflower are of the very best of our older Apples. Possibly were they exhibited to-day as new they would secure high awards. But they are old, and there is no money in them. It may be that they are not universal croppers, but when Apple censuses result in the placing of but very moderate Apples in the foreground, just because they are widely grown and better ones are not, then is such return very misleading.

Had we an Apple census for flavour solely Cornish Aromatic and possibly Cornish Gilliflower would take high places. After all we have very few Apples that rank high for flavour. When we make Cox's Orange Pippin our standard of flavour, except in some of the old varieties, there seems to be a big drop. Blenheim Pippin would be one selected, but its fruits for table are better from an old standard tree on good soil than those from a bush or garden tree. Gravenstein, the old Cockle Pippin, Pitmaston Russet, Golden Pippin, Adam's Pearmain, and Sturmer Pippin in their seasons would probably all stand higher for flavour than many newer Apples, although so handsome. Charles Ross has developed the Peasgood parentage so much that in spite of its first-class certificate it is disappointing. A republication of the names of all those varieties which took prizes in the Veitch competition for flavour at the Drill Hall would be interesting matter. A. D.

THE BRISTOL AND BATH AUXILIARY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—We are desirous of making better known the purpose and work of the Gardeners' Royal Benevolent Institution, and of increasing the funds of the Bristol and Bath Auxiliary. The institution, founded sixty-six years ago, provides pensions for gardeners and their widows over sixty years of age disabled or incapacitated from work, and with an income of less than £30 per annum. It now spends in this way about £4,000 yearly, and has during its existence distributed £100,000. That the need is great is evidenced by there being more than forty gardeners whose candidature was approved by the examining committee unsuccessful at the last election. To carry out our purpose we have decided to inaugurate in 1905 a Rose show, the profits arising

therefrom to be devoted by the auxiliary to increasing the number of local life members, as a donation to the parent society, or as contributions to two special funds of the society, viz., the Victorian Era Fund and the Good Samaritan Fund. As this will be the first flower show held in Bristol exclusively for a charitable purpose, we hope it will be supported not only by all lovers of horticulture, but all the generously-disposed residents of the district, and that the number of annual guinea subscribers will be largely increased. (Every subscriber of one guinea has five votes at the yearly election of annuitants.) The members of the auxiliary and their friends have guaranteed £100 towards the necessary expenses of carrying out the show. The expenses will be more than this. Will you help us either by becoming a guarantor, a subscriber to the show, or a donor of a special prize? The show will be held early in July. We do not ourselves propose to give money prizes. As the show is held for a charity we appeal to the generous instincts of all cultivators to help us to make the exhibition a grand floral success without pecuniary reward. Medals and certificates will be presented in order of merit.

On behalf of the committee of the Bristol and Bath Auxiliary,

W. A. GARAWAY, *Chairman.*

W. E. GROVES } *Joint Hon. Secretaries of the*

H. KITLEY } *Flower Show Sub-Committee.*

34, Elliston Road, Redland.

CARNATION DUCHESS OF FIFE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The border Carnation is such a popular flower with everyone who has a garden that you may think it worth while to publish the photograph I send you of the variety Duchess of Fife. I wish to emphasise its value as a flower for the town garden. Near a large Midland town it has done well with me this summer, and I shall certainly grow more another year. The rich pink slightly fringed petals make up a flower that is delightful in a small garden.

Birmingham.

T. W. F.

HORTICULTURAL "FAKES."

[TO THE EDITOR OF "THE GARDEN."]

SIR,—If he has done nothing more, Mr. Arthur R. Goodwin has struck a note of originality in his

CARNATION DUCHESS OF FIFE.

proposition (see page 342) to start a society for the protection of the British public against horticultural "fakes." Mr. Goodwin would be pleased to hear from any reader of THE GARDEN who is willing to co-operate; but before expecting this

your correspondent should explain a little more clearly what he means by "fakes," and give an outline of his scheme. As Mr. Goodwin uses the word in connexion with Potatoes I take it that he wishes to infer that the new varieties for which long prices have been, and are being, paid are "fakes." If so, then I think the public should be left to protect itself, and if a man chooses to pay a guinea for a Potato which he knows nothing about, except what the vendor tells him, when he could get, say, 5cwt. of a variety that has been tried and proved for the same money, he enters into the transaction with his eyes open, and if he is "taken in" that is his own look out. It strikes me that the inflated prices of Potatoes, and the disappointment in some cases are due to the spirit of gamble or speculation which is characteristic of the average Briton.

G. H. H.

ORCHIDS.

LÆLIA PUMILA AND VARIETIES.

SOME of the varieties of this beautiful dwarf Lælia in the collection of Mr. Jeremiah Colman at Gattton Park are illustrated

by the accompanying photograph. These were shown in his group at the Royal Horticultural Society's meeting on the 1st ult., when a gold medal was awarded. Lælia pumila Gattton Park variety was awarded a first-class certificate by the Royal Horticultural Society on September 21, 1897. This is perhaps the nearest approach to a blue form in Lælia. The flowers are of good size and substance, the petals and sepals very lightly shaded with a slaty rose colouring; the front part of the lip is practically a solid mass of slaty blue, the basal portion being orange-yellow. It will be interesting to watch the effect this peculiar colouring will have in hybridising. Many crosses have been made at Gattton Park, and some are well forward. Lælia pumila var. George Prince of Wales has pure white petals and sepals, the lip being white with the exception of two irregular small blotches of purplish red. The flower is of good shape, and has much substance.

Lælia pumila The Queen is considered at Gattton a model for shape and substance. The petals and sepals are bright rosy red, the lip is immense and very deeply coloured. Another good point is that the petals and sepals do not reflex like most forms.

As they take up but little room, and when well treated make a very fine show, they should be extensively grown.

W. P. BOUND.

WORK FOR THE WEEK.

CALANTHES.

MOST of the foliage on the earliest-flowering sorts has now fallen, so practically no more water is required; some of the later ones, such as *C. vestita* Regnierii, *C. v. Turneri*, and *C. v. Regnierii sanderiana*, still have some green foliage, and will require water until it has matured. They are now one of

the chief sights in the Orchid houses. Those that do not produce an erect raceme are best shown when secured to a slight stake and drawn to the desired position. The popular *C. Veitchii*, *C. Wm. Murray*, *C. Florence*, and *C. Bryan*, if they have been well exposed to sunlight, will be strong enough to carry their flowers without the aid of stakes. Now that *C. Wm. Murray* and *C. Bryan* have become more plentiful, all growers of *Calanthes* should add them to their collection. They are robust, and will become as popular as *C. Veitchii*.

There are many other very beautiful forms, but in most cases they are as yet too rare to have in quantity, and for places where Orchids are grown for decoration it is far preferable to grow a fair number of a few than a few plants of many. The full beauty of *Calanthes* is only seen when they are grouped in masses. As the flowers begin to expand they are best suited if they are removed to a somewhat drier and cooler house, and to obtain the best effect arrange them among *Adiantum cuneatum*, with light Palms for a background.

PHAIUS.

These are still growing freely, yet discretion must be used in watering. In a humid house from

RARE AND BEAUTIFUL VARIETIES OF LÆLIA PUMILA AT GATTTON PARK.

now till the early spring months very little direct watering is required; but if the position is one that dries quickly damp freely between the pots. The hybrids obtained from *P. tuberosus* require more water than *P. grandifolius* and the like. What growers should aim at is to have the compost just humid, and keep it in that state by freely damping, so that direct watering is only needed at long intervals.

Many of the hybrid *Phaius* are very beautiful, and take up much less room than the old *P. grandifolius* and the assanistic varieties, producing spikes of fine flowers freely about 2 feet in height. They are very prolific in producing off-shoots, so that a stock can soon be raised. Among the best are *P. × Cooksonii*, *P. × Norman*, *P. × Marthiae*, and *P. × amabilis*. These will, without doubt, be grown extensively for general decoration by many gardeners who do not profess to cultivate Orchids. They are far more useful than some winter flowering plants, and less difficult to grow.

Gattton Park Gardens, Reigate.

A GENERAL CALENDAR.

PROTECTING ROSES.

FROST usually occurs in this month, and everything should be in readiness for winter protection. Dead leaves should have been collected by the end of November, Bracken should have been cut and got ready, not in heaps but in sheaves; all material for this purpose should be kept dry. It is, perhaps, best to commence the protection as soon as the Rose planting is finished, for should a severe early frost come before the tender Teas are attended to it may cause much lamentation.

Hedge Briars.—These for budding next summer should be planted without delay. Trim and plant them the same day as they are taken from the hedgerows if possible. When trimming leave on every bit of fibrous root. Burnt earth and garden refuse should be freely used in the soil when planting; this will help the Briars considerably to make fresh roots. When a few tall Briars can be obtained these should be planted with a view to

budding some of the charming new wichuraiana hybrids on them; these will make most interesting features in any garden.

Pruning standard fruit trees.—Beware of the travelling fruit tree pruner or the man who cuts away large branches. This method only induces the tree to make more wood. The principal object should be to thin out the branches so that the sun and air may penetrate to every part. All standard fruit trees should be allowed to assume their natural habit of growth. Some throw out their branches horizontally, others are almost upright. Some are drooping; such should not be interfered with. A reduction of redundant or misplaced branches, together with all useless spray and dead spurs and shoots, should only be effected. Fantastically formed heads of standard fruit trees only tend to defeat the real object for which the latter were planted.

Winter management of greenhouse.—Abundance of air must be admitted on all favourable occasions, more especially after those plants which may have been set out of doors for a season have been brought in again. Avoid crowding, which of all things is the most to be found fault with in greenhouses. All superfluous shoots should be removed from climbing plants trained over the roof or otherwise so as to obstruct the rays of light as little as possible. The plants should be carefully examined, cleared of insects, and such as appear to be defective in drainage or want potting must be attended to.

Blackberries.—These have continued to fruit longer than usual this season, and although there is little flavour in those ripening now they give a variety. The foliage, too, assumes a beautiful colour late in the season. There are few places where a vacant wall could not be found for a few of these plants. They require no particular

cultivation, though when well grown better flavoured fruit and a greater quantity may be gathered.
Norwich. T. B. FIELD.

FRUIT AT THE COLCHESTER SHOW.

HARDY fruit was the special feature of the autumn show held on the 10th ult. Over 600 dishes of Apples were in competition, and the Pears also went into hundreds, but the latter were not equal to the first-named for general excellence, still there were some splendid fruits, notably Pear Doyenné du Comice, and the classes for cooking Pears brought forth some splendid fruits. I have never at a provincial show seen such good dishes of Apples or a larger number of competitors. It is impossible to give a list of all the varieties staged, and I will only mention the names of a few. For many years the Rev. Dr. Bartrum of Wakes Colne has offered prizes for fruits at this show. He stipulates that they be correctly named, and gives the prizes in twelve classes. This year he was placed second. I feel sure Dr. Bartrum will be pleased to see his efforts to improve fruit culture in Essex doing good, and certainly in no part of the country has fruit culture improved so much in so short a time. There were fifty classes for fruits, so that it will be seen that Colchester is in earnest as regards fruit culture, and in some there were over twenty competitors. A good rule at this exhibition is, that when there are over ten competitors a fourth prize is awarded. This is a point the Royal Horticultural Society would do well to follow, as they only give two, and this is very hard on the exhibitors.

The leading place for dessert Apples was strongly contested, and Mr. O. G. Orpen, the well-known Rose grower, was first, with superb fruits of King of Tompkin's County, Allington, Cox's and Ribston Pippins, Washington, and Cornish Aromatic, beautifully coloured and of perfect shape. Cornish Aromatic is not often staged, but here it was very fine. In this class Dr. Bartrum was third. All through the dessert classes Allington Pippin was excellent, and Mr. R. W. Wallace had the best in a strong competition, the fruits being perfect. This is evidently a good grower on the Essex heavy soil, and the quality was fine. For the best dessert dish in the show Mr. O. G. Orpen was first with King of Tompkin's County, and the fruits were cut to test flavour; very fine Cox's Orange Pippin, well

shown, the fruit beautifully coloured; also Blenheim Orange, not too large. The first prize for the best dish of champion cooking Apples was secured by Dr. Bartrum; Mr. O. G. Orpen being first in the class for six varieties.

A great feature are the classes for Pippins, Pear-mains, Russets, Nonpareils, and the Spice Apple, an Essex fruit that is largely grown and better known in other districts as D'Arcy Spice or Baddow Pippin. A class for American and Canadian Apples was interesting, and there was no lack of exhibitors; but at this show the fruits in most cases were not equal to our own, though some of the best were noticeable for their splendid colour.

The best flavoured Pears were Doyenné du Comice, and this was seen throughout the exhibits. Beurré Diel and General Toddleben were good also. All the fruits at this show must be grown in the open. This is an important point. After the Royal Horticultural Society's rules, the Blenheim Pippin and Gascoyne's Scarlet were restricted to 3 inches for the dessert—an excellent rule, as huge dessert Apples are not required. Exhibitors may stage large fruits in the cooking classes. The classes for fruit grown in the borough were excellent. G. WYTHES.

AN ENGLISH GARDEN IN AMERICA.

OLD WORLD flowers in a New World garden! Old-fashioned plants in a new-fashioned country! How strange and lonely they would have felt, how utterly out of place, were it not that American forethought and English skill had prepared a home from home for them, and planted them in suitable soil and amid familiar surroundings. The picture we show is part of the English garden at the great St. Louis Exhibition, planted by Messrs. Carter and Co., the famous seed merchants of High Holborn, with those homely and intimate plants that produce what, for the want of a better name, we term old-fashioned flowers; and, indeed, they are old-fashioned in comparison with the florists' latest productions, which may be said to represent the other extreme, the newest of new-fashioned. From what we learn these lovely English flowers in a typical English garden gave much pleasure to American enthu-

siasts, a fact that cannot fail to give us satisfaction when we consider the associations that cluster round them, the memories that cling to them in the mind of many a one at home.

THE KITCHEN GARDEN.

FRENCH BEANS IN LATE AUTUMN

WE have tried various ways of getting French Beans in late autumn, and the results have not been at all satisfactory when the usual methods of forcing were adopted. There can be no doubt whatever that more care is required to get good forced vegetables before Christmas than after, and this applies particularly to such things as must set their flowers at the worst season of the year. Of course, such roots as Seakale and Asparagus are more readily forced when the top growth ceases, especially if a check can be given just before the forcing, but even then those who force will know how much easier the work is done when the roots have had a longer rest and the plant given more time. French Beans, in my opinion, sown, say, late in October for a late autumn supply, are most unprofitable, as they are forced hard. There is no great difficulty in growing the plant, but in setting the flowers, and here we have had many failures. I saw a large grower who had a good number of empty houses sow French Beans, with the result that he did not get enough Beans to pay for the seed. This was, however, in the Thames Valley, so that different results might be obtained in the sunny south or more favoured localities. I have sown repeatedly 100 pots of Beans early in November for Christmas and not had 100 pods. The flowers do not set, and even when they do the small, tender pods drop in foggy weather. This happens with plants grown in beds or heated pits.

Our successes have been obtained at a small cost. Having a number of heated pits or frames with a flow and return pipe round to keep out frost, the seed was sown in the pits the last week in August and the middle of September. No heat was given until early in November, and only then a little in damp weather with sufficient ventilation to maintain a healthy atmosphere. I like new seed, as this results in a more vigorous plant. We still grow Syon House largely for forcing, and this, in addition to its dwarfness, is very prolific. Another very early variety given a trial this season is Veitch's Early Favourite, which is a larger Bean than Syon House, the latter being a little earlier. Veitch's Early crops grandly, and as it combines size with productiveness it is most useful. The seeds are sown thinly; indeed, a strong plant is of the greatest importance. If at all thick we thin freely, and I place much importance upon keeping the growth as sturdy as possible, as I think too much heat in the earlier stages causes failure later on. Some is essential for the flowers to set freely in October and November. This done the pods swell, and the plant is better able to stand the vicissitudes of our season, where so many changes take place. It is also well to grow the seed in soil not too porous. I find we get a much stronger plant by using good loam. This well enriched is preferable to light sandy soil, and it is equally important to grow near the glass; indeed, our greatest crops this autumn have been from plants nearly touching the glass, but with cold nights, say, in October or later, a little warmth in the hot-water pipes and a chink of air keep the plants growing freely. Plants grown thus flower well, and set their pods, but the growth is less rapid than of plants in strong heat. On the other hand, the produce is more natural, the pods are better shaped, of thicker substance, less stringy, and the quality is finer than in Beans hard forced. The pods can be gathered

CARTER'S FLOWERS IN THE OLD ENGLISH GARDEN AT ST. LOUIS EXHIBITION. THIS GARDEN WAS AWARDED THE GRAND PRIZE.

daily if sufficient frames or pits can be spared for the work. Of course, for a regular supply a good quantity is necessary, but in large gardens where glass is plentiful there is no difficulty in maintaining a regular supply.

This plan is useless if the seeds are sown later than the dates given. I have done this with very poor returns. A period of nearly three months is required for the plants to crop well.

G. WYTHES.

THE FACTOR POTATO.

WHATEVER may be the result when published of the returns sent in from each trial centre of the various twelve varieties grown on all the National Potato Society's plots, I may say that on our Surrey centre The Factor was much the best, giving a crop at the rate of four bushels to the rod, and a fine table sample. Up-to-Date, British Queen, Royal Kidney, Evergood, Cramond Blossom, King Edward VII., Empress Queen, Sir J. Llewelyn, and others coming lower. In a single tuber trial of Potatoes, inclusive of twenty-five varieties, each tuber ranging from 4oz. to 9oz. and planted 4 feet apart, quite remarkable growth resulted; The Factor gave from the one plant 17lb. of fine tubers, King Edward coming next with 15lb., Warrior 14lb., Evergood 13lb., Great Central 12lb., King Loth 12lb., and others much lower down. Hence in two independent trials The Factor has proved to be a wonderful cropping Potato, and its table quality is excellent.

A. D.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

THERE was quite a small show in the Horticultural Hall last Tuesday. The finest display was made with Chrysanthemums by Mr. H. J. Jones, who was awarded a gold medal.

ORCHID COMMITTEE.

Present: Mr. Harry J. Veitch (chairman), Messrs. James O'Brien, W. A. Bilecy, de B. Crawshaw, F. J. Thorne, R. Brooman White, H. A. Tracy, H. T. Pitt, J. Wilson Potter, J. Charlesworth, W. H. Young, A. A. McBean, Francis Wellesley, Walter Cobb, J. G. Fowler, W. Boxall, James Douglas, J. W. Odell, H. Little, and G. E. Moore.

A silver-gilt Flora medal was awarded to G. C. Raphael, Esq., Castle Hill, Eglefield Green (gardener, Mr. H. Brown), for an extensive exhibit of *Cypripediums* prettily arranged with the help of bright foliage plants. C. lathamianum, C. apicatum, C. leucanum, and others, including some seedlings raised at Castle Hill were comprised in the group.

Messrs. James Veitch and Son, Limited, Chelsea, exhibited some very choice Orchids, prominent among them being *Cypripedium insigne* Sandere, of which a dozen plants were shown. Cattleya Mantini, Lelia-Cattleya olethelyensis, L.-C. Cassiope, L.-C. Norba, L.-C. digbyana-purpurea, L.-C. Daphne, Lelia Mrs. M. Gratrix, and others made a welcome bit of colour. Silver Flora medal.

Mr. F. Wellesley, Westfield, Woking, exhibited some beautiful *Cypripediums*, e.g., C. *insigne* Chautinii Lindeni, C. *leucanum* Queen of Portugal, C. *l. aureum* Westfield variety, C. *Norma magnificum*, &c.

Cattleya *labiata autumnalis alba* var. was shown by M. C. Beranck, 36, Rue de Babylene, Paris.

A vote of thanks was given to Messrs. Hugh Low and Co., Enfield, for a few choice *Cypripediums*, such as C. *insigne* Ernestii var., C. *l. Laura Kimball*, C. *l. Harefield* Hall, C. *arthuraeum pulchellum*, C. *l. Sandere*, C. *callosum* Gratrix, and others.

NEW ORCHIDS.

Catasetum pileatum aureum.—This curious and also handsome plant was exhibited by Mr. T. B. Schlesinger, Bedales, Hayward's Heath. The flower is large and open, the lip being broad, concave, with a slight spur. The two petals are curiously formed and situated; their margins recurve into the concave upper sepal, partly hiding it, while the two lateral sepals emerge above the lip. The white column is erect, terminating in a bent point, and having two pointed appendages at the base. The colour of the whole flower is primrose-green, while in the centre of the lip, around the entrance to the shallow throat, there is a mass of deep sulphur-yellow. First-class certificate.

Lelia-Cattleya Pallas magnifica.—The parents of this beautiful flower are *Lelia purpurata* and *Cattleya dowiana*. The flower takes after C. *dowiana* in form. The sepals and petals are mottled with bluish rose upon a white ground, while the large, open lip is richest purple. From G. F. Moore, Esq., Chardward (gardener, Mr. H. Page). First-class certificate.

Cypripedium Miss Blanche Moore.—This is said to be a cross between *leucanum* and *insigne* Harefield Hall variety. A delicate colouring pervades the flower. The upper half of the dorsal sepal is white, the lower half green, spotted with light brown. The petals are mottled with brown upon a light green ground, and the pouch is more heavily marked with brown. From G. F. Moore, Esq. Award of merit.

An award of merit was given to a *Cypripedium* shown by M. C. Beranck, but we were unable to find a flower.

FLORAL COMMITTEE.

Present: Mr. H. B. May (chairman), Messrs. George Paul, Charles E. Shea, H. J. Jones, H. J. Cutbush, W. Cuthbertson, Charles Dixon, Charles Jefferies, R. Hooper Pearson, Charles Bick, George Reuthe, J. Jennings, J. F. McLeod, John Green, R. C. Notcutt, J. W. Barr, W. P. Thomson, George Nicholson, E. H. Jenkins, W. J. James, C. J. Salter, Edward Mawley, and Charles T. Drury.

Mr. H. J. Jones, Lewisham, staged a most imposing lot of Chrysanthemums in bold epergnes and stands that displayed to advantage these fine autumn flowers. The group was arranged on the cross stand at the end of the hall, and with ample space in the foreground a fine effect was secured. Some of the more important of this grand lot were F. S. Vallis, yellow; Edith A. Fuller, bronze and gold; Dorothy Pywell, white; Donald McLeod, golden; Mrs. Swinburne, ivory white; Bessie Godfrey, fine yellow; Mrs. Boosey, pink; and H. Stevens, rosy pink. In addition there were single and decorative kinds, lightly interspersed with Crotons and Ferns, with handsome Palms in the background. Gold medal.

The winter-flowering zonal Pelargoniums from Messrs. Cannell and Sons were a most brilliant lot, set up in their usual good style. This firm also showed a few Chrysanthemums, Beauty of Swanley, ivory white; Mytilene, very rich orange gold, a grand colour; and Alliance, pale yellow, very charming. Singles and the spidery forms were also shown.

Messrs. W. Wells and Co., Redhill, contributed a fine lot of Chrysanthemums on boards and in vases, the single and decorative sorts making a light and elegant arrangement. Not least among the more noticeable kinds were the Anemone-flowered Edward Bell, a yellow sport from Sir Walter Raleigh, a bluish white kind. The small-flowered Indicum was also shown, together with Mme. E. Roger, with greenish flowers, and many single varieties. Of single kinds Herbert Henderson is rosy lilac, very pretty; Mme. Cadbury is a fine large white; Countess of Harrowby, pale pink; and Dora Stevens, rosy cerise. Silver Banksian medal.

Messrs. Ambrose and Son, Cheshunt, filled an entire central table with choice cut flowers, as Carnations, Chrysanthemums, Roses, Arums, Lily of the Valley, and other such things, interspersed with market-crown plants, as Heaths, Solanums, Cyclamens, Palms, Ferns, Lilioms, and the like. The arrangement was good, but as the cut flowers in no instance were named we cannot more definitely refer to an exhibit which, from the decorative point of view, possessed merit. Some charming Liberty Roses were in this lot and were very fragrant. Silver Banksian medal.

Messrs. Veitch and Sons, Limited, Chelsea, filled a large table with their well-known winter Begonias. The plants were set in groups of several feet each, and consisted of John Heal; the very charming pink-flowered Agatha; Mrs. Heal, fiery crimson; Julins, a double-flowered pink kind; Winter Cheer, and Ensign, a really excellent lot, and very striking at this season. *Jacobinia chrysostephana*, J. *coccinea* (a most valuable plant for winter work), *Reinwardtia tetragyna*, and *Lindenbergia grandiflora* with drooping yellow flowers were also in this group. Silver Banksian medal.

The Hon. W. F. Smith, Greenlands, Henley-on-Thames, showed a batch of *Hippeastrums* in flower, not remarkable for good form or distinct or good colours, but showy, and from the decorative standpoint quite invaluable at a season when Chrysanthemums are on the wane.

Chrysanthemums were contributed in the cut state by Messrs. R. H. Bath, Limited, Wisbech, Guinea Gold being a most pronounced yellow. Crimson Globe, a useful shade of colour, with golden reverse, was also shown.

Messrs. Cutbush and Sons, Highgate, showed a nice lot of Tree Carnations in the cut state, which were much admired. We note the following as among the best: America, scarlet; Mrs. S. J. Brooks, white; Nelson Fisher, pink, very showy; The President, fine maroon-crimson; Lord Chas. Beresford, a fine flaked kind, very handsome and fragrant.

Mr. H. B. May, Upper Edmonton, filled a table with *Begonia Gloire de Lorraine*, B. *Turnford* Hall, and B. *Mrs. Leopold de Rothschild*. These are rose, white, and pink forms of the one plant, and are most serviceable at the present time. *Primula obconica* in variety, *Dracena Her Majesty*, a richly coloured kind, with Palms and small Ferns completed the group. On the floor were *Poinsettias*. Silver Banksian medal.

Mr. L. R. Russell, Richmond, contributed a fine lot of Ivies, mostly as standards and of the tree section, in company with a large number of well berried plants of *Aucuba vera* and *Eunonymus*. The *Aucubas* were most noteworthy, and their value at this season is beyond question. Silver Banksian medal.

Mr. A. Smith, Enfield Highway, contributed Carnations in pots in variety. Coronation, reddish scarlet, and Princess Victoria, pink, were noticed.

Carnations in the cut state also came from Messrs. Bell and Sheldon, Guernsey, and among these we noted Enchantress, pale pink; The President (see "Awards"), Judge Hindall, Nelson Fisher, deep pink; Reliance, white; Mrs. Lawsoo, and Mrs. Leopold de Rothschild.

Bonvardias were shown by Mr. John Robson, Bowdon Nurseries, Altrincham.

NEW PLANTS.

Cotoneaster angustifolia.—A very handsome and free fruiting plant. The leaves are small, 2 inches or so long, linear lanceolate in outline, green on the upper surface and whitish beneath. The fruiting branches are beset with rigid spines half an inch long. Fruits flattish and round, of shining orange colour, and produced in close clusters of about three dozen on leafy spurs some 3 inches long. The plant is a valuable addition to good garden climbers, and may be briefly described as a climbing Sea Buckthorn, with glossy berries in great abundance and profusion. From M. Maurice de Vilmoren, Paris. First-class certificate.

Chrysanthemum Mrs. T. Dalton.—A large massive flowered Japanese of a crimson tone with cerise, the reverse of the

petals of a silvery tone. A flower of enormous size. Exhibited by Mr. N. Molyneux, Wickham, Hants. Award of merit.

Chrysanthemum Mrs. Schubert.—A massive Japanese with broad curling florets of good texture. There is a firm crisp touch in the petals of this that speak well for its lasting properties. It is a flower of the largest size, and will assuredly figure freely in the best stands another year. Exhibited by Mr. H. J. Jones, Lewisham. Award of merit.

Carnation The President.—A handsome Tree Carnation, with fragrant flowers of a crimson-maroon shade on long stems. Award of merit.

Carnation Enchantress.—One of the largest yet seen in the pink flowered group. The handsome flowers are of the size of a Malmaison and of a pale pleasing tone of colour. Award of merit.

Carnation Adonis.—A rich scarlet kind, one of the best of its colour. Award of merit. These three were exhibited by Messrs. Bell and Sheldon, Guernsey.

Platanicum albicorne Mogi.—A seedling from P. a. majus, possessing a very elegant and graceful habit, the arching fronds more drooping and the lobes more deeply cut and pointed. Only a small sample was shown, but the character was pronounced even in this, and when compared with the type and P. a. majus the difference is all the more marked. From Mr. H. B. May, Edmonton. Award of merit.

FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. A. H. Pearson (chairman), Messrs. James H. Veitch, J. Willard, G. Reynolds, W. Pope, George Kelf, H. Parr, Alex. Dean, S. Mortimer, James Gibson, E. Beckett, J. Cheal, and Owen Thomas.

Sir Charles Russell, Bart., Swallowfield (gardener, Mr. S. Cole), was awarded a silver-gilt Knightian medal for an excellent collection of fruit. The Apples were richly coloured, the Melons very fine for the time of year, and the Muscat of Alexandria and Alicante Grapes, too, denoted the best of culture. Apples Peasgood's Nonsuch, Mère de Ménage, King of Tompkins's County, and Cox's Orange Pippin were particularly good. Some dishes of Pears were also included.

Messrs. W. and J. Brown, Stamford, Peterborough, and Grantham, exhibited a small collection of Apples and Pears. The former were finely coloured, and included Blenheim Orange, Adam's Pearmain, Cox's Orange Pippin, Tyler's Kernel, Cox's Pomona, and others. Pears Ne Plus Meuris, Passe Crassane, Beurré Diel, Josephine de Malines, and Belissime d'hiver were some of the best exhibited.

A vote of thanks was given to Mr. W. Roupell, Roupell Park, S.W., for a basketful of Apple Chelmsford Wonder, grown within five miles of Charing Cross. There were several other dishes of Apples before the committee, but no awards were made. Apple Fenn's Wonder, shown by Mr. T. Simpson, gardener to the Earl of Stradbroke, Hensham Hall, Suffolk, is a large, handsome ribbed fruit.

A silver Knightian medal was awarded to Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere, Newbury, for a collection of Onions, Sutton's Crimson Globe, Challenge, Anglo-Spanish, Blood Red, White Spanish, and others were included. Seed was sown the first week in March, the seedlings being planted out in April.

A most interesting exhibit was that from Mr. F. Powell, Park Place Gardens, Henley-on-Thames, of retarded Potatoes, each carrying a crop of young tubers. The old tubers shown were put in a cucumber frame on October 17 last. Good dishes of new Potatoes may be had from September to February. This method of raising new Potatoes was fully described and illustrated in THE GARDEN, July 16, 1904. Silver Banksian medal.

EDINBURGH CHRYSANTHEMUM SHOW.

THIS show, held in the Waverley Market, Edinburgh, on the 17th, 18th, and 19th ult., was the most successful since the series was inaugurated by the Scottish Horticultural Association. We were, unfortunately, unable to publish a report last week. In point of numbers it showed an increase of entries; the quality of the exhibits, as a whole, was superior to that of any former year, while the attendance of the public was the largest on record. The cut blooms were of superior quality to those at the last show. The chief interest lay in the competition for the City of Edinburgh Memorial Prize, for which there were seven competitors, each with fifteen vases of Japanese blooms in fifteen varieties, three blooms of each. Here Mr. T. Lunt, Keir, carried off the cup with a splendid lot of great beauty and of almost equal merit; Mr. D. Nicoll, Rossie, was a good second; third, Mr. James Beisant.

Much interest was also taken in the Scottish Horticultural Association's Queen Alexandra Prize, confined to those within the municipal boundaries of Edinburgh and Leith. The blooms were, as a rule, of splendid quality. First, Mr. James Fraser, Kilravock; second, Mr. W. Lamont, Colinton Road; third, Mr. W. Michie, Boroughfield. There was strong competition for the Scottish Challenge Cup, and good blooms were shown, the prizes going as follows: First, Mr. D. Kidd, Carberry Tower; second, Mr. G. Stewart, Tulliehallan Castle; third, Mr. R. Addison, Leuchie. The other classes for Japanese were well contested. Incurved were well shown, Mr. J. Martin, Corndean Hall, Winchcombe, being first. Single and decorative Chrysanthemums were good and the competition strong. The classes for bouquets, sprays, vases, and epergnes were well filled, and many of the exhibits very tasteful.

Plants were of much the same merit as last year, the leading prize-taker with Chrysanthemums being Mr. W. Pulman, Hollywood, Colinton Road. The trade floral exhibits brought out only two competitors, the first prize going to Messrs. Todd and Co., Sandwick Place, for a display of floral designs of exquisite beauty. The third prize was awarded to Mr. W. Jobson, Southfield Nursery, Portobello. Miscellaneous plants call for no special notice, but were equal to those of last year.

Fruit was a most attractive section of the show. In the Grape classes Mr. J. Leslie, Pitcullin, had matters practically all his own way, winning five first and one second prize in the seven classes. Mr. W. Galloway, Gosford House, was first

for Muscat of Alexandria, and Mr. M. Millan, Douglas Castle, was first for Lady Downe's. Mr. D. Kidd, Carberry Tower, was first for the collection of eight varieties of fruit. Apples were very well shown, and were finer than those of last year.

In the classes restricted to Scotland Mr. C. Webster, Gordon Castle, Pochahlers, was first for eighteen varieties, Mr. R. Grindrod, Whitefield, Hereford, being first in the unrestricted classes. Mr. F. Jordan, Impney, was awarded the Association's gold badge for the best collection of hardy fruit grown in the open, and the first prize for six Pears; Mr. J. Day, Galloway House, winning for six Pears grown in Scotland. In the market gardeners' classes for Apples Mr. G. Mackinlay was first.

Vegetables were capital, and the competition was good. Mr. W. Reid, Dollarfield, Dollar, beat Mr. E. Beckett, Aldenham, with his collection of ten varieties; but the competition must have been very close. Mr. W. Harper, Tullibeltoun, was third.

Mr. D. M. Michan, Hillfoot, Dollar, won with six varieties. The other vegetable classes were well filled and of excellent quality.

The trade exhibits were a great attraction, particularly those of Mr. H. J. Jones, Mr. W. J. Godfrey, and Messrs. W. Wells and Co., Limited. Mr. Jones made a splendid exhibit of Chrysanthemums, beautifully arranged, for which a gold medal was awarded. Silver medals were awarded to Messrs. Wells and Co. and Mr. W. Godfrey. Messrs. James Grieve and Sons, Dicksons and Co., J. Dickson and Sons, W. Crutsh and Son, and others showed flowers or plants; Messrs. W. Drummond and Sons and Mr. Hugh Dickson showed splendid Apples and Pears; and Mr. T. W. Scarlett, Edinburgh, and Messrs. W. Davis and Co., Haddington, sent Potatoes. The show was a great success, and the arrangements exceedingly well made.

BORDER DISTRICT CHRYSANTHEMUM SHOW.

THIS show was held this year at Selkirk. The entries showed an increase of ninety over last year's show, which was held at Hawick. Both in number of entries and in point of quality this show has shown a steady improvement since its inception in 1890, and this year's exhibits were generally of high-class quality.

Mr. A. Bruce, Gala House, Galashiels, was first for eight vases Japanese; Mr. J. Clark, Bannerfield, Selkirk, Mr. D. May, Abbotshill, Galashiels, and Mr. J. Reilly, Galahill, being the other prize winners in the classes for Japanese cut blooms. Mr. J. Clark had the best twelve incurved blooms; Mr. A. Bruce the best three vases decorative; Mr. W. Gowenlock, Kingsknowes, Galashiels, was the most successful in the Chrysanthemum plant classes; Mr. J. Reilly had the best group of plants; Mr. W. Gowenlock the best foliage plants. Other prize winners with various plants were Messrs. J. Mowat, J. Kinnear, D. May, and W. Buckham; the last named had the best Grapes, and Mr. T. Gray and Mr. A. Bruce the best Apples. Mr. J. M. Turner, Galashiels, had the best collection of vegetables. The amateurs' classes were very creditable.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday, the 21st ult., the executive committee of this society held a meeting at Carr's Restaurant, Strand, when the president, C. E. Shea, Esq., occupied the chair. Mr. Richard Dean, the secretary, was, unfortunately, prevented from attending through illness, but his place was taken by his son, who read the minutes of the previous meeting and various correspondence in connexion with the recent show. An interesting statement as to the attendance at the Crystal Palace show was read, by which it appeared that the number of visitors was considerably in excess of those at last year's show. It was stated that prize money to the value of £268 14s. was awarded to exhibitors on that occasion, and this, too, was gratifying, it being in excess of the prize money awarded in the previous year's November show. A list of medals awarded was also read. Owing to the secretary's absence no financial statement could be rendered, but it was promised for the next meeting of the committee, and was said to be satisfactory. The following dates were agreed upon for the 1905 exhibitions, viz., October 4 and 5, November 1, 2, and 3, and December 6 and 7.

The meetings of the executive committee were also fixed, and are as follows:—September 18, October 23, November 20, and December 11, 1905, and January 15, 1906. The floral committee will meet at the Essex Hall on September 18, October 23, November 20, and also at the Crystal Palace on the first days of the three shows, viz., October 4, November 1, and December 6.

The usual resolution was passed inviting the members of the floral committee to a dinner at the end of the season. Twenty-one ordinary members were elected and one Fellow, and the business was brought to a close with a hearty vote of thanks to the chairman for presiding.

ANNUAL DINNER.

The annual dinner of this society was held at the Holborn Restaurant on the 23rd ult., Mr. C. E. Shea, president of the society, being in the chair. There were over a hundred persons present.

After the usual loyal toasts, that of the National Chrysanthemum Society was proposed by Mr. Bunn, in the absence of Mr. E. T. Cook. Mr. Bunn said he admired the work of the society's members and also their special flower. He thought the society was deserving of great praise for the many lessons it has taught and the great perfection to which it has helped to bring the Chrysanthemum.

In reply to this toast the president, Mr. Shea, first expressed the great regret of himself, and he was sure of those present also, at the enforced absence of Mr. R. Dean through illness. Mr. Dean had always discharged his duties as secretary very satisfactorily. Referring to the great advance in the Chrysanthemum from the type, *C. indicum*, Mr. Shea said that English and French growers and raisers were chiefly responsible for this. Those who doubted the wisdom of the society in going back to the Crystal Palace to hold its shows must have been reassured by this year's display there. He said many criticisms—some good, some bad—had been

levelled against the methods of exhibiting blooms, and while the society was quite of opinion that it must break new ground and must progress, critics often forgot the difficulties in the way of transporting flowers with long stems. Mr. Shea went on to say that the entries at the last Crystal Palace show were so numerous as to refute Mr. Molyneux's statement in the *Gardener's Magazine* that they had diminished. Mr. Shea said there were twenty-six entries in one class alone, and wondered how many there used to be.

Mr. George Gordon proposed the toast of "The President, Vice-President, and Other Officers of the Society." In the course of his remarks Mr. Gordon said how much they all regretted the absence of Mr. Dean; the manner in which he had done his duties was beyond all praise. Mr. T. Bevan replied. Mr. C. Harman Payne gave "The Affiliated Societies," to which Mr. Alderman Bishop replied. The toast of "The Chairman" was entrusted to Mr. Whitty. Other toasts were "The Ladies and Visitors" and "The Press."

During the evening the National Challenge Trophy (presented to the Epsom and District Society) was received by Mr. Hunt, their chief exhibitor. Mr. Higgs was presented with a Challenge Trophy and Holmes Memorial Cup which he had won. Mr. Mease also received a Holmes Cup for his success during the past season.

BRISTOL CHRYSANTHEMUM SHOW.

BRISTOL was one of the first centres to form a Chrysanthemum society, but it is a question if the society at any time held a better show than on the 16th and 17th ult. in the Colston Hall. The indefatigable efforts of the secretary, Mr. Groves, and his assistants did much, assisted by fine weather, to make the exhibition so marked a success.

CUT BLOOMS.

For twenty-four incurved Mr. S. W. Drake, the well-known Cardiff grower, was placed first with a good set of well-grown blooms; Mr. F. May, gardener to H. O. Lord, Esq., Lilley Brook, Cheltenham, was second. With beautiful blooms Mr. H. Baker, gardener to Dr. Cropper, Mount Ballan, Chesham, was placed first for twelve incurved.

For thirty-six Japanese blooms: A Challenge Vase valued at fifteen guineas was awarded with the first prize in this class, the conditions being that it must be won three times by the same exhibitor before becoming his property. Mr. Vallis of Chippenham last season finally secured a vase of this description, and his exhibits were missed at Bristol on this occasion. Among six exhibitors, however, The Frome Flower and Fruit Company were first, and staged fine blooms; Mr. May was a good second.

For twelve Japanese: Eight highly meritorious stands were staged in this class, the chief one by Mr. Baker. A bloom in this collection of Mrs. F. W. Vallis was awarded the National Chrysanthemum Society's silver medal as the best flower in the show. The second position was secured by Mr. Pope, gardener to C. Bailey, Esq. A class of the same kind for gentlemen's gardeners and amateurs found Mr. Pope leading, with Mr. Baker second, amongst eight exhibitors. Provision was made for large-flowered Anemone varieties by a class for twelve. Here Mr. Black, gardener to Mrs. W. Pethick, was placed first, Mr. Strugnell being second.

VASES OF CUT BLOOMS.

The classes provided for these attracted considerable notice, and deservedly so. The class for six distinct varieties attracted six competitors, and of these Mr. Sutton, gardener to W. A. Todd, Esq., was first; the Frome Flower and Fruit Company were a good second. Mr. Perry, gardener to H. Nell, Esq., was placed first for six blooms of any white sort, followed by Mr. Sutton, while Mr. J. C. Pope, gardener to C. Bailey, Esq., in a splendid class, was first with F. S. Vallis for six blooms of any yellow variety.

FRUIT.

In a class for six dishes Mr. Raikes, gardener to W. A. F. Powell, Esq., was placed first amongst seven exhibitors; second, Mr. Strugnell, gardener to the Right Hon. W. Long, Lord Ashton.

For six dishes of dessert Apples there were no less than eighteen lots. First, Mr. Strugnell, with a splendid set; Mr. G. Runnacles was a close second.

In the classes for dishes of dessert and cooking Apples the leading prize-takers were The Cedar Hardy Fruit Company, Mr. Jay (gardener to T. K. Yalland, Esq.), Messrs. G. Farmer, Lord, Colwell, Strugnell, and Runnacles.

Pears, six dishes: With excellent fruit Mr. Bannister was first, and was followed by Mr. Farmer. With four dishes Mr. Bannister was once more placed first in a good class, Mr. Colwell being placed second. Mr. Runnacles was first for Doyenné du Comice.

Grapes: These were largely shown, nine classes being allotted, but there were some weak stands amongst them. The best bunch in the show was staged by Mr. Mitchell, gardener to J. W. Fleming, Esq., in his first prize lot of Muscat of Alexandria; Mr. J. Ollis, gardener to C. E. Whitting, Esq., was second in this class. Fourteen exhibitors staged in a class for Black Hamburgs, Mr. Morse, gardener to W. H. Lindred, Esq., being first. Mr. Mitchell was again first for Mrs. Pines Muscat. Mr. Coote won for Alicante, and also for Lady Downe's Seedling. Mr. Spry won in the class for Gros Colmar. Collections of vegetables were numerous and of excellent quality.

PLANTS.

Many fine specimen plants of Palms, ornamental foliage plants, Ferns, &c., were staged, and they made an imposing display down the centre of the large hall. Mr. Bannister was the chief exhibitor of Ferns, and Mr. Benfield of ornamental foliage plants. Begonias were shown by Mrs. Coleman, Poinsettias by Sir Charles Care, Cyclamens by Messrs. Blackmore and Langdon, Primulas by Mr. McCulloch, Nepenthes by Mr. E. White, and dinner-table plants by Mr. Bruce, gardener to L. White Esq. Mr. Crane was first for a group of miscellaneous plants 50 feet square. For a group of Chrysanthemums, 50 feet square, Mr. Bannister was the sole exhibitor, and was deservedly awarded the first prize. The

best twelve Tea Roses were from Mr. J. Hobbs and Mr. Bannister, while Violets were splendidly shown by W. Price Jones, Esq., J. L. Waller, Esq., and others.

Non-competitive exhibits did much towards contributing to the show's success. They were from Messrs. Cooling and Sons, Bath; Messrs. Garaway and Co., Bristol; Messrs. Parker and Sons, Bristol; Messrs. Dobson and Co., Bristol; Mr. Godfrey, Exmouth; Mr. Vincent Slade, Tamilton; Messrs. Blackmore and Langdon; Messrs. Carter and Co.; and Messrs. Ambrose and Sons, Cheshunt.

READING CHRYSANTHEMUM AND FRUIT SHOW.

DELIGHTFUL weather favoured the twenty-first—the "coming of age"—show of the Reading Chrysanthemum Society, which was held recently in the Town Halls, Reading; and the occasion was marked by a huge attendance.

The general entries totalled no less than 390, as against 240 last year; but this great increase is mainly to be accounted for by the abnormal number of competitors in the classes for Apples, there being no less than 550 dishes of this fruit entered in competition, while over 100 lots were shown "not for competition."

There were two competitors in the leading open class for a group of Chrysanthemums. Mr. Charles E. Keyser, of Aldermaston Court (gardener, Mr. Galt), was first; and Mr. Walter, of Bear Wood (gardener, Mr. W. Barnes), second. Mr. Keyser's group secured the challenge cup, which was last year awarded to Mr. Walter for a remarkable display, on which comments were made at the time. Lady Cooke, of Easthope, Reading (gardener, Mr. Exler), was first for a floral display.

Mr. W. Pole Ronth, of Oakfield, Reading (gardener, Mr. Honse), was an easy first for three specimen distinct varieties in 9-inch pots.

In the open classes for cut blooms, Japanese and incurved, and vases and bunches or sprays, there was keen competition of the usual excellence, but space only admits of our referring readers to the prize list.

In table decorations Mr. Walter's gardener (Mr. Barnes) was an easy first. In the section for subscribers employing not more than two gardeners, Mr. W. J. Justin Brinn's gardener staged a very fine lot, beating groups shown by Lady Cooke and other exhibitors.

In the fruit classes many grand bunches of Grapes were staged. Black Alicante produced a large entry, the Duke of Wellington's tremendous bunches beating those beautifully coloured staged by Mr. F. Cole, gardener to Sir Charles Russell, of Swallowfield Park. The class for Lady Downe was headed by Mr. G. C. Raphael, closely followed by Mr. M. H. Fournet Sutton, of Broad Oak, Reading (gardener, Mr. Fooks). In the class for two bunches of white Muscat of Alexandria, Sir Charles Russell's beautifully coloured bunches defeated those sent by Mr. G. C. Raphael and the Duke of Wellington.

As usual, a notable feature of the show was formed by the exhibits "not for competition."

DUNFERMLINE CHRYSANTHEMUM SHOW.

THE show of the Dunfermline Chrysanthemum Society was opened in St. Margaret's Hall, Dunfermline, on the 25th ult. The number of exhibits was greater than last year, while there was also a general improvement observable in the larger number of the classes. The cut blooms were noteworthy for their size and finish, plants were good, and the vegetable classes had some produce of the highest quality. In the open classes for cut blooms the first prize for twenty-four Japanese was won by Mr. J. M. Proctor, Comely Park; Mr. W. Lunley, Broomhall, being first in the class for twelve; and Mr. J. Simpson, St. Leonard's Hill, in that for six. Other leading prizes in the cut bloom classes were won by Messrs. Proctor, Simpson, and T. Reid, Hawthornbank. Mr. T. Reid had the best six incurved; Mr. J. Simpson the best Japanese bloom in the hall; Messrs. Reid and Simpson led in the classes for vases. In the plant classes Mr. J. Walker, Priory House, led for six pots; Mr. H. Boaz, Moodie Street, for three; Mr. T. Reid, Mr. J. Reid, Mr. J. Reach, and Mr. R. Haldane were the other first prize takers in these classes. Mr. T. Campbell, Pittencrieff, had the best lady's spray and bouquet; and Mr. R. Izatt the best button-holes. The leading winners in the classes for plants were Messrs. Fraser, Lumley, Marshall, and J. Reid. The principal winners with vegetables were Mr. W. Reid, Dollarfield, Dollar, Mr. W. Lunley, Mr. J. Brown, Middlebank, Mr. J. M. Blyth, Cockburnie, and Mr. J. M. Birkett, Dunfermline. The show was very successful.

READING AND DISTRICT GARDENERS' ASSOCIATION.

THE last meeting of this association was given up to the reading of the first prize essays in the senior and junior divisions in the recent competition on Carnations. The two successful competitors were Mr. W. Turnham of Culham Court Gardens, Henley-on-Thames, and Mr. H. Wynn, The Gardens, Cressingham, Reading. After the essays had been read, a good discussion took place, sustained by the chairman, Messrs. Powell, Tunbridge, Ellis, Townsend, Chambers, Dore, Judd, Hinton, and Winsor. There were two exhibits, both remarkable for the time of year, viz., twelve splendid fruits of a seedling Melon, by Mr. W. H. Barnes, The Gardens, Bear Wood, and some beautiful blooms of Cactus and Pompon Dahlias, cut from the open, by Mr. T. J. Powell, The Gardens, Park Place, Henley-on-Thames.

LEITH HORTICULTURAL SOCIETY.

THE annual meeting of this society was held on the 21st ult. It was reported that the expenditure for the year ending October 31 amounted to £466 3s. 5d.; the balance being £4 16s. 3d. Some discussion regarding the expenditure on some of the departments was engaged in. The following office-bearers were appointed:—President, Mr. J. H. Tait; secretary, Mr. W. Millar; treasurer, Mr. D. Macalpine. It was agreed to convert the society into a limited liability company.

THE GARDEN

No. 1725.—VOL. LXVI.

DECEMBER 10, 1904.

THE WASTE OF GARDEN GROUND.

THERE are hundreds of gardens about the country where there is a lamentable waste of good garden ground, and the productive capacity of which is sadly restricted.

Especially is this true of old gardens which are found attached to residences built many years ago. These have become the picture of neglect, and many new ones, by reason of unskilful or inappropriate planting, or by planting things unsuited to the soil and position, fail completely to yield profitably. Unfortunately, many who are the possessors of such gardens are careless as to their condition, mainly perhaps because they fail to see improvement is practicable, though when a change is made, as sometimes happens, and a gardener who knows his business takes one in hand, this change for the better is at once discernible.

Let us look into one of these neglected gardens, and what meets the eye? We see old and useless trees that shut out the best of the morning sun, and prevent anything like the ground beneath them being cropped to advantage. Shrubs planted singly or in clumps have outgrown all reasonable dimensions and encroached upon soil that would otherwise be productive, or they have grown tall and, becoming bare at the base, are unsightly objects. Then there are overgrown hedges that rob the extent of the garden of many yards of good ground, and which might be cut in, as in the case of the shrubs, and converted into Pea sticks, firewood, &c., or be burnt to supply wood ashes. One sees fruit trees and bushes crowded and cankered, overgrown and interlacing each other, and occupying ground for which their annual crops prove no equivalent. In the gardens of the working classes, and especially of agricultural labourers, there are to be seen many overgrown trees shading the ground and preventing the growth of green crops which would prove far more remunerative and acceptable—gardens that with better cultivation might be made to produce double what they do and everything of better quality if the tenants could be made to increase their interest in cultivating them, cutting down an old Maple or an overgrown Elder in the hedgerow, repairing broken-down fences, cutting the hedge close in, making the walks few and straight and no wider than

3 feet, and covering every inch of fence or house-wall with something useful or beautiful.

In the summer we were called upon to go through a group of English villages and make awards to the best gardens. The most favourably tilled and cropped gardens were those where the cottages had as inhabitants workmen following other occupations than those of agricultural or garden labourers. Some were working carpenters or bricklayers, or men who were following some occupation on their own account, and in nearly every case the gardens were remarkably well kept. Perhaps the farm and garden labourer, after following work all day, found any continuation of it in the evening somewhat irksome and monotonous, while to the artisan it came as an agreeable change from a mere mechanical occupation. Many of these cottage gardens were far too large to be kept in anything like good condition by the head of the family, who had but little, if any, daylight in which to work in autumn and winter, and if such gardens could be divided among two or three occupiers, or a portion employed to rear some agricultural crop, it would be better than allowing them to go to waste as they do now.

THE ALPINE HOUSE IN DECEMBER.

ALTHOUGH this house at the present dull time of the year is not so attractive as it will be in another few weeks, there are several interesting plants in flower, and many others which show an early promise of brighter things to come. It is very interesting to watch the development of the various plants, and much pleasure can be derived from the observation of the different stages through which the flowers pass before the petals expand. It is true that a great many pots which contain bulbous plants have only a few points just breaking through the soil, and present a bare, unsightly appearance. By the use, however, of evergreen plants with pretty and distinct foliage, like *Galax*, *Shortia*, crusted and mossy *Saxifragas*, *Sedum*, and others of like character judiciously mixed with them, this bareness may be to a great extent obviated, and the house made to present a furnished appearance. Of the plants in flower the most beautiful is the Scorpion Iris (*I. alata*), with its delicate lilac-blue blooms, the first of which was produced in October, and which promises to continue till the beginning of the new year. This plant is well adapted for this purpose, as, although it will grow in a sunny position outside against a south wall, its delicate flowers are liable to be spoilt by the splashing of heavy rains. With the shelter of

the cold alpine house, however, it is enabled to develop its full beauty, and materially assists in making the house attractive when the plants in flower are very few. Also in bloom is the distinct and charming Megasea-leaved *Primula* (*P. megaseaefolia*), with its broad green leaves and trusses of rose-purple flowers. Although a comparatively recent introduction from Asia Minor, this plant promises to soon become popular, as it is so easily increased by dividing the root after flowering into single crowns and growing on, when they soon make nice plants.

The Meadow Safrons are represented by the useful and pretty *Colchicum libanoticum*, which is found on the mountains of Lebanon in Syria, and which has flowers varying from rose colour to white. These are produced in succession, several from each bulb, the flowering period extending from the beginning of November to January. *C. Decaisnei*, also from the East, is beginning to throw up its flesh-coloured flowers here and there in the pans, but it will probably be the end of the month before they are all in bloom. Another distinct little *Colchicum* from Syria is *C. Steveni*, which is also in flower. It is closely allied to *C. montanum*, with rose-coloured flowers varying almost to white. The leaves, of which there are about five or six to each bulb, are long and very narrow.

Of the winter-flowering Crocuses in bloom there is *C. marathonisius*, from Mount Taygetus in Greece, with its golden-throated, pure white flowers. This is a handsome species, with flowers of good size, freely produced. *C. hyemalis*, a native of Palestine, is a delicate little plant. It enjoys the distinction of having the most southern range of all the Crocuses. Like most of the other species of this genus its flowers are variable in colour, some pure white with a golden throat, while others have purple lines on the outsides of the segments near the base. The variety *Foxii* has flowers with black anthers. Other Crocuses in flower are *C. caspius*, from the Caspian region, with large white or pale lilac flowers, and *C. levigatus*, a pretty species from the mountains of Greece. The flowers of the latter vary from white to lilac, and are distinctly feathered with purple markings on the outer segments.

One or two early flowers are just opening on *Saxifraga apiculata*, with many others almost ready to burst. *Alyssum Bornmuelleri*, a pretty compact-growing plant from Asia Minor, has been in flower for a long time, and is still producing its small white blooms. The beautiful little Algerian Hoop Petticoat Daffodil (*Narcissus monophyllus*) is almost ready to expand its pretty flowers. Exceedingly useful plants for the alpine house are the hardy *Cyclamen C. coum* and *C. ibericum*, the former with dark green round leaves, and the latter having a pale zone. They present a well-furnished appearance, and the flowers with their rose-coloured points are already showing above the soil. Most easily grown,

they stand pot treatment well, flowering annually and lasting for many years.

Of the plants remarkable for their foliage perhaps the most conspicuous is *Shortia galacifolia* with its richly coloured leaves. In this condition it is almost, if not quite, as attractive as when in flower. A pleasing plant also is *Galax aphylla*, with its large, thin leathery leaves on long stems. Many of these, which are green in summer, turn to a rich red-brown in autumn and early winter. The *Saxifragas* are rich in material, suitable for the alpine house in winter, both the crusted and mossy sections containing many distinct and interesting species of evergreen habit. *S. longifolia*, with its large rosettes of leaves, is a handsome plant, well worth a good place. Other distinct crusted species are *S. catalaunica*, a somewhat rare plant from Northern Spain, with broad crusted margins to its leaves; *S. cochlearis* and its smaller variety *minor*; *S. crustata*, and *S. aizoon* in its many forms. Among the mossy set suitable for their rich green foliage to break the bare appearance of the many pots of bulbs may be mentioned *S. caespitosa*, *S. decipiens*, *S. hypnoides*, and *S. trifurcata* and its variety *ceratophylla*. *S. cuneifolia* and its varieties are also good evergreen plants.

Many of the *Sedums* are useful, including *S. album*, *S. dasyphyllum*, the North American species *S. obtusatum* and *S. ternatum*, as well as the distinct Mexican *S. Stahlii*, with its very fleshy, red-brown leaves on wiry stems. These give an interesting variety, and the *Sempervivums* can furnish many suitable plants for this work, including *S. arachnoideum* and var. *Laggeri*, *S. globiferum*, *S. Funckii*, *S. mettenianum*, *S. Pomelii*, *S. Schottii*, and *S. triste*.

Pretty plants are some of the silvery-leaved *Artemisias*, and easy to grow in pots, although they suffer a good deal through damp during the winter in the rock garden. Among the best are *A. Baumgartenii* (from South-eastern Europe), *A. lanata* var. *pedemontana*, and *A. vallesiaca* (a native of Switzerland and the Piedmont).

Interesting plants are the two hardy *Selaginellas*, *S. Douglasii*, from North America, and *S. helvetica*, a native of the European Alps. They both form bright green carpets, lasting fresh throughout the winter. *Thymus azoricus* is a tufted plant from the Azores, with compact evergreen foliage. In the *Achilleas* we have several species with leaves of a silvery hue—*A. Griesbachii*, *A. Huteri*, *A. serbica*, and *A. umbellata*. The *Cerastiums* are represented by *C. alpinum* var. *lanatum*, *C. Biebersteini*, and *C. tomentosum*. Other evergreen plants include several species of *Draba*, *Androsace lanuginosa* and *A. sarmentosa*, *Nocca alpina*, and *Erodium chamaedrioides*. These plants mentioned by no means include all those suitable and interesting enough for use as pot plants in the alpine house in winter, and many more may be used with advantage.

W. IRVING.

RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for December contains portraits of

Kalanchoe Dyeri.—Native of Nyassaland. This is a very handsome plant, with thick, fleshy, deeply-toothed foliage, and large bunches of large Crassulacike flowers of a delicate shade of rosy white.

Cydonia sinensis.—Native of China. This is also known under the synonyms of *C. chinensis*, *Pyrus sinensis*, *P. cathayensis*, and *Chionomeles chinensis*. It is a very large golden-fruited and handsome Quince, with very ornamental rose-coloured flowers with a deeper centre.

Lonicera syringantha.—Native of North-west China. This is a very pretty and free-blooming Honeysuckle, with small rosy flowers resembling those of the Himalayan species, *L. tomentella*, but produced in much greater profusion.

Odontoda Faglschecker.—Of garden origin. This is quite one of the most strikingly beautiful hybrid Orchids ever seen, and created a sensation when exhibited by its raiser for the first time at the Temple show this summer. It is the result of a cross between *Cochlidia nezliana* and *Odontoglossum nobile* of Reichenbach or *Pescatorei* of Linden. Portraits of single flowers of both parents are also shown on the plate, which is extremely instructive and interesting to Orchidists. A very large price was offered for this plant during the show, but it did not change hands, and was taken back to Belgium.

Tulipa Batalini.—Native of Turkestan. This is an extremely bright and pretty Tulip, one of the eleven species which are natives of Turkestan. It has medium-sized flowers of a clear pure canary yellow, with an orange band round the base of the petals and centre of flower.

The second part of the *Revue Horticole* for November figures

Hydrangea hortensis rosea and cerulea.—This plate is given to show that the rose-coloured flowers of the ordinary form of this well-known shrub can be changed to a fine deep blue by cultivation.

The first number of the same publication for December figures

Eucalyptus piceifolia.—A native of New Holland. This handsome plant is quite the most beautiful and ornamental member of its family, whose flowers are generally white of various degrees of purity, while its flowers are in one form of a fine deep crimson, and in another (also figured on this plate) of a delicate shade of pink.

The December number of *Revue de l'Horticulture Belge* gives a fine double plate of a large new Japanese Chrysanthemum named *Monsieur Antonin Marmontel*.
W. E. GUMBLETON.

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

December 13.—Royal Horticultural Society's meeting at the New Hall, Vincent Square; Exhibition of Colonial-grown Fruits, and of Home, Colonial, and Foreign Jams and Preserved Fruits.

December 14.—East Anglian Horticultural Club meeting.

January 3, 1905.—Royal Horticultural Society's meeting.

January 24.—Royal Horticultural Society's meeting.

Royal Horticultural Society.—This society will hold a special show of Colonial fruits, &c., on Tuesday and Wednesday next. All exhibits of Colonial fruit, &c., and of British bottled fruits, jams, &c., must be staged on Monday next, and be ready for the judges at 4 p.m. At 5 p.m. the council hold a private view of the show, to which representatives of the Press and a few guests have been invited. Any space not required for exhibits under the special schedule will be allotted for groups of flowers, &c., as usual, but such exhibits can only be accepted on the special understanding that they will be staged before 11.30 a.m. on Tuesday, and will be left on view for the whole duration of the show, which will remain open till 10 p.m. on Wednesday. Plants shown for certificate only will be allowed to be removed at 4 p.m. on Tuesday.

The new Victoria Medallists of Honour.—The following three gentlemen have been selected to complete the list of the sixty-three Victoria Medallists of Honour; the vacancies were called by the deaths of the Dean of Rochester, Mr. Smith of the Mentmore Gardens, and Mr. Herbst. Mr. Challis is one of the most able and best respected of British gardeners. For over forty years he has held the position of head gardener to successive Earls of Pembroke at Wilton House, Salisbury. In the west of England his name is a household word

in gardening circles, and he is much in request as a judge at exhibitions. Mr. Challis has especially interested himself in fruit culture; he was one of the first to recommend the method of growing Peaches under glass on upright trellises fixed at right angles to the back and front walls, instead of the flat trellis arranged below the roof, as is most usual. A very good horse lawn-sweeping machine used in gardens was devised and brought out by Mr. Challis. The Royal Horticultural Society could hardly have found a worthier and more typical representative of the gardeners of this country upon whom to bestow the coveted Victoria Medal than Mr. Challis. Mr. Edward Mawley is widely known as the honorary secretary of the National Rose Society, and his hard and persevering work has had such far-reaching results as to make further commendation unnecessary. In former years as co-secretary with the Rev. H. d'Ombrain, and for the past three or four years as sole secretary, Mr. Mawley has, with the help of other workers, been instrumental in widening the influence and promoting the good work of the National Rose Society. In the selection of Mr. Mawley as a recipient of the Victoria Medal all Rose growers will feel that a better choice could not have been made. His work for the Meteorological Society must also be remembered. Mr. A. Dean has filled many and various posts in the horticultural world. As a County Council lecturer, one who has interested himself in the promotion of cottage and allotment gardening, as a valued contributor to horticultural journals, as a member for many years of the Royal Horticultural Society's fruit committee, as an expert among vegetables and author of an excellent manual, "Vegetable Culture," as well as in other ways, Mr. Dean has done good work for gardening. Few men are more widely known among gardeners. Mr. Dean acted as secretary to the committee who organised the great gardeners' meeting and dinner held last year.

The Royal Horticultural Society and its advantages.—The New Year is approaching with rapid footsteps, and among its promised gifts are the plants distributed by the Royal Horticultural Society to its Fellows, such a delightful set of plants which you are allowed to select from a list sent out in January—hardy, half-hardy, and stove plants, the newest and best varieties, and Fellows residing beyond thirty-five miles from London, according to the A B C Guide, are entitled to a double share. The plants are beautifully packed and in such perfect condition that, though I have been the lucky recipient for several years, I have not lost one. Those who are not yet Fellows will be in time to receive their share of the distribution if they send in their subscription at once. Of course, there are many other advantages accruing from a Fellowship. The Society's Journals are worth the subscription alone, and a £2 2s. subscriber gets all these advantages, with one non-transferable pass and two transferable tickets for all the shows and meetings. All amateur gardeners should become Fellows of the Royal Horticultural Society, and should write for information to the kind and courteous secretary, the Rev. W. Wilks, M.A., 117, Victoria Street, S.W.—L.

National Sweet Pea Society.—The annual general meeting of this society will be held at the Hotel Windsor, Victoria Street, S.W., on Tuesday next, at 2.30 p.m.—HORACE J. WRIGHT.

The late Mr. G. T. Miles.—The obituary notice on page 374 of the late Mr. Miles will be read with much grief, as horticulture has by his death lost a thorough supporter. Many can claim a longer friendship with him than myself, but no one enjoyed his society more. The notice in THE GARDEN, which states that Mr. Miles received so much encouragement from his noble employer must be most gratifying to the great body of gardeners employed in this country. What a gain to the employer and the employed when such sympathy exists between them. Our late friend was always ready with his kindly advice and assistance to do all in his power to help those who needed it. I deeply sympathise with his family. We wished him a longer life to enjoy the rest that he had so well earned.—G. WYTHES.

Annual meeting of the National Dahlia Society.—This will be held in the North Room, Hotel Windsor, Victoria Street, Westminster, S.W., on Tuesday, the 20th inst., at 3 p.m. A meeting of the committee will be held at 2 p.m.—P. W. TULLOCH, *Hon. Secretary, Forest Cot, Balcombe, Sussex.*

The fruit industry of Great Britain.—The departmental committee appointed by Lord Onslow to enquire into and report upon the fruit industry of Great Britain held sittings on the 24th and 25th ult. The following members were present: Mr. A. S. T. Griffith-Boscawen, M.P. (chairman), Colonel Long, M.P., Mr. C. W. Radcliffe-Cooke, Mr. Monro, Mr. Hodge, Mr. Vinson, Dr. Somerville, Mr. P. Spencer Pickering, M.A., F.R.S., the Rev. W. Wilks, and Mr. Ernest Cansey (secretary). Evidence was taken from the following witnesses: Mr. J. F. Leaf, representing the Elementary Education Branch of the Board of Education; Mr. Frederick Keeble, Principal of the Horticultural Department of the University College, Reading; Mr. A. Buck, representing the Surveyors' Institute; and Mr. Vincent Hill, General Manager of the South Eastern and Chatham Railway, representing the Railway Clearance House.

Planting wall climbers.—In your issue of the 19th ult. you give an excellent illustration of *Hedera amurensis* on a wall at Hatfield. The photograph emphasises very well the only too common mistake which is made when planting climbing varieties of Ivy and other wall plants. The plants have been allowed to grow upwards from the time when they were put in, thus leaving bare and unsightly spaces uncovered on the lower portion of the wall. If the growths of each plant were trained out horizontally on either side along the base of the wall, by subsequent development the whole surface would be covered. Attention to this small but important detail at the time of planting will avoid the unsatisfactory result shown in your illustration.—F. H. MATTHEWS, *Knapp Hill, Surrey.*

Deutzias for forcing.—Among the "Answers to Correspondents" in THE GARDEN for November 26 reference is made under the head of *Deutzia gracilis* to the great value of *D. candidissima* as a shrub for forcing. It is, indeed, a beautiful flowering shrub; but being a variety of *D. crenata*, which blooms naturally out of doors about midsummer, it cannot be had under glass as early as *D. gracilis* and the nearly allied forms. A hybrid variety—*D. Lemoinei*—has in many parts of the country not fulfilled the expectations that were formed of it as an outdoor shrub; but for forcing it is one of the most useful of the entire genus, though for this purpose *D. gracilis* is second to no other. *D. Lemoinei*, just alluded to, was obtained by M. Lmoine of Nancy by fertilising the flowers of *D. gracilis* with the pollen of the Chinese *D. parviflora*, a comparatively recent species. From *D. gracilis* the newer *Lemoinei* differs in being altogether a larger, stouter, and straighter grower, while the individual flowers are large and pure white. It is now an established favourite for forcing, and large numbers of it are grown by some of the Dutch nurserymen who make a speciality of shrubs for this purpose. A form of this, known as *D. Lemoinei compacta*, is announced by M. Lemoine, but of its forcing qualities I cannot speak from experience, though in growth it is certainly more compact than the type.—H. P.

Chrysanthemum indicum (Linn.). Among the *Chrysanthemums* in No. 4 greenhouse at Kew at the present time is a group of *C. indicum* on one of the beside stages. This is one of the parents of the most popular flower of autumn. It seems almost incredible that a plant can be so changed by the hybridist and cultivator. The original plants from which these are cuttings were raised

from seed collected by Mr. Grant Birch in the Yangtze Valley above the rapids. It is a widely distributed plant in China and Japan. Extremely variable in a wild state, it has at various times had at least five generic and a dozen specific names. Three figures are given in the *Botanical Magazine* under the name *C. indicum*—tab. 7874 is the subject of this note; tabs. 327 (dark red) and 2042 (changeable white) are now both referred to as *C. morifolium* (Ram). The plant is of rather slender and straggling growth. Cuttings rooted in December and pinched several times will form bushes 3 feet 6 inches high and as far through by the flowering season. The plants which are the subject of this note were grown from cuttings rooted in March and pinched once. They are in 6-inch pots and about 2 feet in height. The flowers are single, slightly larger than a shilling, and of a pleasing yellow colour.—A. OSBORN.

Some good winter flowers.—Those who possess glass houses naturally like to see them filled with the brightest and showiest plants possible at this time of year, when the outdoor garden has lost its interest, or at any rate its attractiveness. In the group of plants shown at the

semi-double; Winter Cheer, with more red in its colouring, semi-double, and wonderfully free flowering; Julius, double, bright pink, very free; and Mrs. Heal, single, bright rose. Agatha is a miniature Gloire de Lorraine, but the flowers are redder, and Cyrene has drooping double flowers, best described as salmon-pink. John Heal may be said to be a bright rose-coloured form of Gloire de Lorraine.—Y. Z.

TREES AND SHRUBS.

VERONICA TRAVERSII.

THE shrubby species of *Veronica* form an exceptionally interesting group. Unfortunately, they are not very hardy, and, as a whole, are not to be depended on except in the warmer parts of the country. In Devonshire, Cornwall, South Wales, and other places it is a common thing to see great bushes of *V. speciosa* smothered with purple flowers, and very fine they look.

VERONICA TRAVERSII AT KEW.

Horticultural Society's show last week by Messrs. James Veitch several were remarkably bright, and deserve a note to bring them prominently before your readers. Among them are *Lindenbergia grandiflora*, a plant some 18 inches to 2 feet high, with *Salvia*-like leaves and drooping, yellow flowers. This plant belongs to the Snapdragon family (*Scrophulariaceae*), and is a native of the Himalayas. It is given in the Kew list of "Hardy Herbaceous Plants." *Reinwardtia tetragyna* made a brave display with its large bright yellow flowers, a good deal like Evening Primroses, produced in a loose terminal head. This plant used to be grown much more than it is now, and for the sake of its value in the conservatory at this time of year deserves extended culture. *Jacobinia chrysostephana*, bearing terminal heads of erect, tubular flowers of a glowing orange-red colour, is also most valuable at this time of year. Among the winter-flowering *Begonias*, most of them hybrids between the tuberous and the fibrous-rooted sorts, some of the best are *Ensign*, with deep rose-pink blooms; *Winter Perfection*, rather lighter in colour,

About London, however, it is impossible to grow *V. speciosa* out of doors the whole year round, and of the forty or fifty species in cultivation, very few can be said to be sufficiently hardy to stand unharmed through a winter of moderate severity. At Kew *V. Traversii* is found to stand the best, though in a very severe winter it is damaged, but when a succession of mild winters is experienced it becomes strong and sturdy, and grows into a bush 2½ feet or 3 feet high and 3 feet to 4 feet through. Like the other shrubby species, it is from New Zealand.

The leaves are small and deep green, the flowers white with purplish anthers, and borne in short, stiff racemes in summer. The accompanying illustration is of a specimen growing near the Temperate house at Kew. In places where these New Zealand *Veronicas* thrive they should be grown in quantity, for they are beautiful when in flower, good evergreens, and give little trouble. They thrive in ordinary garden soil, and grow naturally into shapely specimens.

W. DALLIMORE.

RHODODENDRON LUSCOMBEL.

This is a most graceful Rhododendron. In April the shrub is covered with bell-shaped blooms of a bright rosy pink, the trusses being large and loose, and very charming with the pale glaucous green foliage.

County Donegal. S. M. WALLACE.

TREES AND SHRUBS WITH COLOURED FOLIAGE.

(Continued from page 378.)

ECONYMUS.—For the warmer parts of the country the variegated forms of *E. japonicus* are useful for beds and other purposes, all the varieties, gold and silver, being good. *E. europæus* var. *atropurpureus* is the best of the coloured leaved forms of the Spindle tree, and is useful for the back of a shrubbery, while the several varieties of *E. radicans*, which have variegated leaves, are useful for forming carpets under trees or for planting in the front of a shrubbery. The variety Silver Gem is useful for planting in beds.

FAGUS.—There is quite a number of varieties of the common Beech, *F. sylvatica*, with bronze or purplish leaves and one or two with variegated leaves. Of the varieties the most distinct are: *F. s. atropurpurea* and *F. s. purpurea major*, with deep purple leaves, *F. s. var. tricolor* with tricoloured leaves, *F. s. variegata* with cream variegation, and *F. s. var. Zlatia* with golden leaves.

FRAXINUS.—Very few of the Ashes have variegated leaves, but there are a few which are worthy of notice. The best are *F. americana* var. *aucubifolia*, with golden variegated leaves; *F. a. var. argentea* variegatis, with silver variegation; and *F. excelsior* var. *foliis argenteis*, with white variegated foliage.

HEDERA.—The variegated leaved Ivies are well known, and whether in the climbing or tree forms they are equally useful. The tree forms, both gold and silver, are extremely useful for forming beds, the two varieties Silver Queen and *arborescens foliis aureis* being specially worthy of mention.

HIBISCUS.—The variety of *H. syriacus* known as variegatus has silver variegated leaves and is a useful shrub.

ILEX.—The numerous variegated varieties of the common Holly are all worthy of cultivation, and most of them are well known.

JASMINUM.—The golden leaved form of *J. nudiflorum* is pretty when in leaf, but is not worth cultivating on a large scale. The same may be said of the variegated form of *J. officinale*.

KERRIA.—The silver variegated form of *K. japonica* is worth growing in the milder parts of the country; in cold districts it is often damaged by frost.

LABURNUM.—*L. vulgare* var. *foliis aureis* is a golden leaved Laburnum of considerable merit, the leaves being well coloured, and retaining their colour through the greater part of the summer.

LIGSTRUM.—The usefulness of the golden leaved form of *L. ovalifolium*, which is commonly called the golden leaved Privet, is well known. It is useful alike for beds, shrubberies, or hedges, and grows well under almost any conditions. The variegated leaved forms of *L. vulgare* and *L. sinense* are not of much value compared with the above.

LIRIODENDRON.—The Tulip Tree is not very often met with in a variegated form, but there is a well marked variety known as *L. tulipifera* var. *aureo-marginata*.

LONICERA.—The only variegated Honeysuckle of any note is *L. japonica* var. *aureo-reticulata*. It is a very pretty golden variegated shrub, and is useful for a small bed or for planting against an old tree root, over which it can spread its tangled branches.

NEILLIA.—*N. opulifolia* var. *lutea* is a handsome golden leaved subject, and as it is a strong grower it is suitable for the back of the shrubbery or other similar position. The best coloured leaves

RHODODENDRON LUSCOMBEI AT ARDNAMONA, LOUGH ESKE, COUNTY DONEGAL.

are borne on young shoots, so the old wood must be kept well thinned.

OSMANTHUS.—The numerous varieties of *O. Aquifolium* are all of horticultural value, and as they are evergreen and neat growing they make excellent subjects for beds. The two best of the coloured foliaged ones are *O. A. ilicifolius purpureus*, with purplish leaves, and *O. A. i. variegatus*, with white variegated foliage.

PHILADELPHUS.—The Mock Oranges have two representatives in the group, *P. coronarius foliis argenteo-variegatis*, with white variegated leaves, and *P. c. var. aureis*, with golden leaves. The latter is the better of the two, and the colour is finest in early summer.

POPULUS.—Several of the Poplars have coloured foliage and are useful for forming groups, as they grow quickly and make large specimens. The white Poplar and its variety *nivea* have grey leaves, *P. balsamifera* var. *variegata* has golden variegated leaves, *P. canadensis* has whitish leaves, and *P. deltoides* var. *aurea* has golden leaves. These are the most showy.

PRUNUS.—*P. cerasifera* var. *atro-purpurea*, otherwise known as *P. Pissardi*, has purple leaves and is a very useful plant, as it always looks well and can be grown either as a tree or bush. The purple leaved Peach, *P. persica* var. *foliis rubris*, is also useful. There are many other variegated Prunuses, but they are of no horticultural value.

PRELEX.—The golden variety of the Hop Tree, *P. trifoliata* var. *aurea*, is well worthy of cultivation; the leaves have a pretty gold colouring, and the plant is worthy a place in a mixed shrubbery.

PYRUS.—There are several species of *Pyrus* with grey foliage, *P. salicifolia* being one of the best.

QUERCUS.—The Oaks are not prolific in variegated foliaged varieties, though there are several of considerable merit. The following are the best: *Q. Cerris* var. *variegata*, with silver variegated leaves; *Q. pedunculata* var. *aurea leucocarpa*, with pretty golden leaves; *Q. p. var. purpurascens*, with purplish leaves; and *Q. rubra* var. *aurea*, with golden leaves.

RHAMNUS.—*R. alaternus* var. *angustifolia* variegata is the best of the variegated varieties. It makes a neat evergreen with silver variegated leaves.

ROBINIA.—*R. Pseud-acacia* var. *aurea* has golden leaves. It is an excellent tree to plant in a mixed

shrubbery, as the light foliage relieves that of a heavier character.

ROSA.—What few variegated foliaged Roses there are are of little value, but the purple leaved *R. rubrifolia* is worth cultivating.

SAMBUCUS.—The Elderberries are represented by several coloured leaved varieties, the best being *S. nigra* var. *aurea variegata*, with golden variegated leaves; *S. n. var. foliis aureis*, with golden leaves, the common Golden Elder; and *S. racemosa* var. *foliis aureis* and *S. r. var. plumosa aurea*, both with pretty golden leaves. All are useful for masses.

SANTOLINA CHAMÆCYPARISSUS.—The Lavender Cotton has silvery leaves and makes a dense mass. It is very useful for beds or masses and rarely exceeds 1 foot in height.

SYMPHORICARPUS ORBICULATUS VAR. VARIEGATUS has golden variegated leaves and is useful for a change.

ULMUS.—Several of the Elms have golden or white variegated leaves and make fine trees. The best are *U. campestris* var. *latifolia variegata*, with large white variegated leaves; *U. c. var. Louis Van Houtte*, with golden leaves; *U. c. variegata*, with white variegated leaves; *U. c. viminalis* variegata, with small silvery leaves and fine twiggy shoots; and *U. montana* var. *aurea* with golden leaves.

Although there are numerous other shrubs with leaves of other colours than green the above-mentioned are the best. W. DALLIMORE.

RHODODENDRON YUNNANENSE.

A COLOURED plate and the following description of *Rhododendron yunnanense* appear in *Flora and Sylva* for December: "The Rhododendrons found within recent years in central China have not only enriched our gardens with hardy kinds of great beauty, but have opened new fields to the raisers of garden varieties in a series of plants of a character quite unlike many of those previously known. From the work of Hooker in northern India that region was long considered as the chosen home of the Rhododendron, but of late years this estimate has been modified in view of the discoveries of MM. David and Delavay in Yunnan and Dr. Henry in south-west China. Their gains have proved that the area in Asia covered by the Rhododendron is wider than at first supposed, reaching eastward

from the Himalayas, through Thibet, into China and Manchuria. The Chinese Rhododendrons are remarkable for their variety of form, and are so completely distinct from those of the Himalayan region that only one or two kinds, out of more than forty now described, are common to both areas. Though amongst these new species there are many kinds which only interest the botanist, some are good plants, beautiful in flower, hardier than most of the Indian section, and certain when they become more plentiful to prove of value in our gardens and shrubberies. Rhododendron yunnanense is one of these beautiful hardy shrubs which was found by Abbé Delavay upon the mountains of Yunnan, and raised from seeds gathered and sent to Europe by him. The plant first flowered at Kew in April, 1897, and has improved with every season, being especially fine this spring when Mr. Moon secured his picture. It is an erect shrub, loosely branching into slender shoots, with scanty leaves of dark green, slightly hairy upon the margin and upper side, and covered beneath with dark glandular dots upon a pale grey surface. Its beautifully marked flowers are nearly 2 inches across when expanded, and borne in profusion as little clusters of four to six blooms; coming somewhat late—from the middle to the end of May—they escape the spring frosts which so often spoil earlier kinds. The spray seen in our plate is that of a pale variety of yet finer effect than the original plant, whose lilac-coloured flowers are shown as a small detached cluster. The plant is hardy at Kew, flowers freely while quite small, though it promises to make a good-sized shrub, and would appear to be of easy increase from cuttings. It received an award of merit in May of last year when flowers were shown before the Royal Horticultural Society by Mr. Moore of Glasnevin, and its value has been so proved as to assure its place among hardy Rhododendrons."

RHODODENDRON MANGLESII.

This beautiful Rhododendron flowers in April and May. It is a cross between R. Aucklandi and a hybrid named album elegans. The flowers are white, upwards of 4 inches across, with purple spots, and are developed in large trusses. It was named after Mr. Mangles, so well known in connexion with the culture of Rhododendrons. S. M. W.

INDIAN SUMMER.

NOVEMBER is a much abused month, and most unjustly so. In this part of the world it is often a time of pleasant outdoor weather.

October, so belauded by the poets, is a month of gales, of much damp and gloomy weather, of sharp frosts and dismal fogs, varied, it is true, by days that are ideal in brilliancy of colouring, when the crisp air is a joy to breathe.

But if October is a month of changes, of upheaval, and destruction, and of the beginning of a new order of things, November often comes to us in a soft and pensive mood, as if she were grieving for the death of the flowers, and longed to delay a little while the avertless approach of winter.

In my last letter I did not mean to convey the impression that the garden is quite stripped of bloom and beauty. If November seems to grieve over the many flowers that her boisterous brother October has laid low in his wild sport, yet she has some of her own which she cherishes tenderly. How sweet still are the beds of Mignonette, of Candytuft, and Sweet Alyssum in these golden afternoons. How we prize the few pale Roses here and there in the long borders, or the round beds on the lawn, where the Rose bushes are making a new start, too late, alas! for much fulfilment for

all their brave show of buds and tender green leafage.

Some Nasturtiums still venture a few belated blossoms; the Marvel of Peru is still "Pretty-by-night," which is its common name among the country folk, and the Dahlias, Marigolds, and a few Cannas are still in evidence. Also the handsome Nicotiana sylvestris is perfuming the evening air in its border. It has a large colony of thrifty seedlings, which it seems a pity to expose to the killing effects of the first black frost. But our facilities for keeping tender plants over are limited. This is not our winter home, and we do not try to carry over many plants. However, we have potted a few Nicotianas. They do not bloom with us the first year from seed unless the seedlings are started very early in the house.

Exceptionally fine are some groups of Tritomas in the rock garden, where they stand in a blaze of sunshine. I have never known them send up such tall flower-stems or so many of them. They seem to improve with age. We mulch them with manure every autumn, and protect with a covering of leaves.

Some Asters are still in flower. One of these that is valuable for November bloom is Aster trinervis, so called from its conspicuously three-veined leaves. This Aster grows from 2 feet to 3 feet in height, and is now pretty with its close heads of large purple flowers.

Aster tartaricus is an Asiatic Aster that is valuable for late autumn. When well grown it forms a noble-looking plant, 5 feet or 6 feet in height, with large leaves, and many stems crowned with clusters of beautiful purple flowers in dense heads.

I have read so many charming descriptions of English rock gardens that I always mention my own attempts at rockery planting with diffidence. The problem that I have before me now is how to plant a very rocky bit of waste ground west of our little Dutch garden. Flat-topped limestone rocks crop out of the ground here and are much overrun by Trumpet Creeper and other trailing and climbing plants. It is necessary to pass this wilderness to get to the little brick-edged

garden where we plant our Tulips, Hyacinths, and many other spring blossoms; and we wish to tame and cultivate, as far as possible, this neglected spot, without resorting to the strenuous work of blasting and removing the rocks.

There are some hopeful-looking crevices between these huge old limestone slabs, and these we have filled with the commonest and least exacting rock plants, such as some hardy single Pinks, creeping Phloxes, Rock Cress, and the very hardy and useful creeping Veronicas.

A pretty little Daphne Cneorum is now in profuse bloom at the base of one of the ledges. We must enjoy its beauty while it lasts, for we have never succeeded in keeping a plant of this or any other Daphne very long at Rose Brake.

We have made some irregular paths through this new rockery, and lined them with some of the flat slabs of rock taken out of the soil in the process of digging the ground. These paths are now bordered with fresh plantings of Aubrietias, hardy Alyssums, and many other kinds of plants, with colonies of Snowdrops, Chionodoxas, and other bulbs.

When a box of these spring bulbs comes from the dealer it often requires some study to decide how to plant them to the best advantage. There are few better places for many of them than the sides of a grassy path in the wilder parts of one's pleasure grounds. The path through a shrubbery of evergreens to the north of the house has had many colonies of Narcissi, Snowdrops, Winter Aconite, Croci, and other bulbs planted on both sides of it between the evergreens. Here, too, are groups of Irises, Dicentras, and other early bloomers.

Pardanthus chinensis, mentioned in THE GARDEN not long ago as a very rare plant in England, has been so freely planted in this neighbourhood that it has naturalised itself in woods and waste places near old houses. We have it in our wild garden. Left to itself it will encroach on choicer flowers and take up room out of all proportion to the beauty of its bloom. It flowers in midsummer, and harmonises well with Lilium pardalinum and Hemerocallis fulva, which are its neighbours. We also have much Cassia marylandica blooming at the

RHODODENDRON MANGLESII AT ARDNAMONA.

same time, a graceful perennial, a native of our marshlands, with pretty pinnate foliage and racemes of bright yellow and black blossoms. The plants die down to the ground every year.

One should live in or near a bit of woodland in which are many white and scarlet Oaks, Tulip trees, Beeches, and Birches, to realise what one of our poets means by the expression "bright-haired November." There is a wonderfully sunny effect about the foliage of these trees, which is intensified by the contrast of many groups of our sombre red Cedars (*Juniperus virginiana*), which grow among them. The red Cedar is our only indigenous evergreen, although we are only a few miles from the "Pine Hills," which are covered with white Pine and Spruce. These evergreens flourish in the slaty soil of our nearest mountain slopes and foothills, but are not found in the stiff clay and limestone of our immediate neighbourhood. The poet who sings of the Golden-rod has given this tender description of the American Indian summer:

"Yes, the sweet summer lingers still;
The hazes loiter on the hill;
The year, a spendthrift growing old,
Is scattering his lavish gold
For a last pleasure.
The robins flock, but do not go;
We share the wood with footsteps slow,
In sober leisure;
Or sit beneath the Chestnut tree,
Our hands in silent company.
Not yet, dear friend, we part not yet,
Full soon the last warm sun will set,
The cricket cease to stir the grass,
The gold and amber fade away,
The scarlet from the landscape pass,
And all the sky be sadder grey.
Too soon, alas! the frost must fall,
And blight the Asters on the hill,
The Golden-rod, the Gentians, all,
And we must feel the parting chill;
But oh! not yet, not yet we part,
The summer strains us to her heart,
The world is all a golden smile,
And we may love a little while,
The summer dies, and hearts forget,
And we must part, not yet, not yet."

DANSKE DANDRIDGE.

Rose Brake, Shepherdstown, West Virginia, U.S.A.

LILIES IN A NORTH COUNTRY GARDEN.

(Continued from page 374.)

LILIUM AURATUM, longiflorum, speciosum, and their varieties will not flourish here. They flower once and once only. After that they make a weak growth for a year or two and then disappear. I am going to try a couple of bulbs of the Shirley variety of auratum platyphyllum, which I hope may do better. *L. candidum* does very well in a sunny position, and I have never seen any trace of disease. The clumps are mulched every year with cow manure as soon as flowering is over. *L. Brownii* is very erratic. I have four clumps of it, of which two bloomed well this year. The flowers were large and very handsome. The other two clumps did not make any growth. They bloomed last year and are taking a year's rest. I find this frequently happens here with this Lily. Three spikes of *L. giganteum* bloomed this year fairly well. Other bulbs of this Lily have been planted two and three years, and though making strong leaf growth each year they have not yet flowered. I hope they will do so next year. *L. croceum* is always good either in sun or shade, in wet or dry seasons, and makes steady increase. *L. elegans* I have tried in several varieties, but for the most part they have shown a strong tendency to dwindle away. Three forms, viz., Orange Queen, Willie Barr, and robustum are, however, doing well and increasing. Orange Queen is a particularly fine form, with large, well shaped orange flowers. It grows about 1 foot high, and is a first-class Lily for a low rockery. *L. umbellatum* (davuricum) in several varieties

always does well and increases. I think that erectum and incomparabile are the best forms, and one or both should be grown for a fine display of bright orange and red flowers in June. *L. Grayi*, canadense, flavum, and superbum all do moderately well. They have been planted three years, and bloomed better this year than in the two previous years. I have had *L. washingtonianum* in bloom for three years in succession, and it seems to be well established. The best spike this year had fourteen fine blooms. The bulbs are planted deep in a mixture of peat and leaf-mould at the foot of a low, well shaded bank. *L. w. purpureum* has also bloomed for the last three years. The best spike this year had six flowers on it. It is also planted deep in peat and leaf-mould.

A clump of five *L. rubellum* gave me three flowering spikes both last year and this; it is a lovely flower. I shall try more of it next year. *L. Henryi* was till this year disappointing, as the flowers did not come into bloom till late in September, and most of the buds were cut off by early frosts in October, but this year it has been quite satisfactory, the first flower opening on August 15. I have three clumps planted on a low rockery, and the stems lightly staked bend over somewhat gracefully. It did not do so well in the border. This Lily should be planted deeply and well manured as it makes very strong stem-roots.

A clump of two dozen *L. tigrinum splendens* made a brave show in September, followed shortly afterwards by a clump of *L. Fortunei* major. Both should be planted fairly deep.

I have failed completely with *L. Batemanniae*, *L. Leichtlini*, *L. tenuifolium*, *L. Krameri*, and *L. Parryi*. The last mentioned I have tried three times planted in sandy peat, both in sun and shade, but so far without success, possibly from want of management.

It will be seen from the above that I have had many failures, but also a fair amount of success, and as the failures are easily forgotten while the joy of success remains, the pleasure of growing these delightful flowers far exceeds the inevitable disappointments.

South Bailey, Durham. T. MADDISON.

NOTES ON HARDY PLANTS.

SCABIOSA CAUCASICA AND ITS VARIETIES.

COLONIES of the Caucasian Scabious in good condition are a source of great pleasure in late summer, the large mauve-tinted, long-stemmed flowers, in loose sheaves 2 feet or more high and 3 inches across the petals of each, are a real boon to the decorator and a great show that one cannot fail to admire. Occasionally one finds this Scabious stubborn to manage, especially in heavy clay soils, where cultural skill seems powerless to encourage it to grow well. Generally, however, it thrives like a weed, and many old-established clumps exhaust themselves in the effort to flower beyond their strength, and are only recuperated by a liberal mulch of new soil and old manure as the young growths develop in spring. There is a white form which, to my mind, is scarcely so good a plant as the typical mauve, and improvements on both known as perfecta and perfecta alba, whose ray florets are much flattened and enlarged, the margins being deeply cut, giving the flowers greater size, and adding greatly to their beauty. These newer forms do not differ from *S. caucasica* in vigour, the only difference being size of flower and breadth of petal, and it is impossible to distinguish much difference between well-grown caucasica and badly-grown perfecta; but treated alike, and both liberally, there is a

great gain in the perfect forms that should do much to render this Scabious even more popular than it is to-day. The white perfecta is a purer white than caucasica alba, and an altogether better plant. G. B. M.

PERENNIAL STATICES.

THERE are some excellent rockery and border plants among the perennial Statice, yet with the possible exception of *S. latifolia*, the familiar Sea Lavender, few of them are put to any effective use, their lasting qualities, undoubted hardihood, and comparatively showy inflorescences being entirely overlooked when planting time comes round and there are blanks to fill. Of rockery species there are several. *Bessieriana*, a rosy purple flowered plant of neat habit; *incana* and its form *nana*, in shades of red, with pretty rosettes of hoary leaves as tough as leather; *speciosa*, whose reddish flowers in silvery calyces are arranged in flat panicles 1 foot across, and whose young leaves are purple tinted; and *altaica*, a dainty Siberian species, with flowers of the richest blue, are among the best of perennial kinds, sufficiently neat in habit for rockery planting.

Border species of stronger growth that are effective in the mass, and which will yield excellent cut sprays that one can use effectively in all kinds of floral decoration, would include *Fortunei*, less tall than most, but extremely pretty when massed, the yellow inflorescences growing 1 foot high; *S. Gmelini*, a rampant grower, and extremely light and graceful in the inflorescence, the flowers a rich shade of violet; *latifolia* and *Limonium*, familiar border plants that are always admired in the flower border, and of real value for cutting, give us blue and grey shades respectively in masses of elegant inflorescences 3 feet across in old-established specimens. There is no difficulty in cultivating Statice, all grow with tolerable certainty in even poor soils. All are easily raised from seeds or increased by root cuttings 1 inch long, being plunged in a bed of sand, where they will root and grow on the slow but sure principle. Statice are not among the showiest of border plants, but they help considerably to fill the flower vases both in summer and (in a dried state) in winter, and one cannot use them too freely to break up and lighten dense masses of colour. G. B. M.

VERBASCUM PHENICEUM.

THE Mulleins are generally acceptable in gardens, the tall stature, imposing appearance, and distinctness of some of the taller species rendering them of considerable importance from a decorative point of view. Many of the most showy have yellow flowers, but there are some species with flowers of a different colour, which may be of considerable value in the border. Among the latter one may well consider *Verbascum pheniceum*, commonly known as the blue-flowered Mullein, although this name is now rendered inappropriate by the introduction of new colours in the plant.

The type, however, has a yellow ground, which is striped with violet. The other colours now secured are generally more beautiful, some of these being white, copper, and various shades of yellow and violet. None is so beautiful as the pure white variety, the purple stamens giving an air of distinction to the plant and forming a good contrast to the purity of the flower. Some of these coloured forms are procurable from seeds, which are often sold as hybrids of *V. pheniceum*, but I fail to see any evidence of hybridisation, and I feel positive that they are merely the results of variation and selection from the typical *V. pheniceum*.

Verbascum pheniceum is a useful flower for the garden, although it becomes a little untidy towards the close of the term of flowering of each spike. It grows from 2 feet to 3 feet high, sometimes even a little more, and has somewhat oval lance-shaped, roughish leaves at the base of the plant in the shape of a rosette, and smaller stem-leaves, which are sessile and alternate. The flower spikes gradually open, beginning at the bottom of the spike. As those at the base are over before the upper ones expand, the

plant becomes rather bare below, so that the spikes ought to be cut off when rather more than half expanded. The plants will then throw up fresh flowers and the season of bloom will be still further prolonged, while the effect will be much better than if the flowers were allowed to remain until all were exhausted.

Although *Verbascum phoeniceum* is hardy in ordinary circumstances, there are some cold and wet gardens with stiff soil where it proves rather unreliable in winter. There it may be treated as an annual, sowing seeds under glass as early in spring as possible, and planting out in May. It is very easily raised from seeds, and a large stock may soon be secured in this way. In light soils the blue-flowered *Mullein* sows itself freely enough, and the writer has reason to consider it too prolific in his own garden. It is, however, a beautiful and distinct plant when at its best, and one would not willingly be without its ornamental effect in the garden. S. ARNOTT.

CHRYSANTHEMUMS.

FRENCH CHRYSANTHEMUMS.

AMONG some of our plant introducers twenty years ago or more it used to be a subject of complaint that many of the novelties sent out with a glowing description of their merits failed to realise the expectations that were formed of them when they were grown here in England. It was pointed out that this was not necessarily the result of intentional deception on the part of the raisers, but may have been attributable to differences of culture or of climate. Even a visit to France by anyone accustomed to appraise the value of novelties does not always result in complete satisfaction, and it is notorious that new things may be shown well at the French shows and yet for some reason fail almost entirely here. While on the Continent last year I had excellent opportunities of seeing most of the season's novelties from all sources, and it may be useful to record the names of those noticed good there and which have also done well this season under English treatment. Several of the foreign raisers are not largely represented, and most of the novelties of foreign origin are those received from M. Ernest Calvat, the eminent grower of Grenoble. These are all in the hands of our leading trade specialists.

Among them the following were shown at the Paris show in 1903 in promising form, and also here this year: Mme. Marguerite de Mons, Mme. R. Oberthur, Marquise Visconti-Venosta, and Mlle. Anna Debono. The like may be said of Calvat's seedlings shown at Lille, which included *Chrysanthemiste Rémy* and *Jos. Paquet*. Among Nonin's seedlings at Lille there was *La Gracieuse*, an incurving flower of pale pearly pink that seems to be equally good in England. It must not, however, be forgotten that home and colonial competition is nowadays much keener than it was in days gone by, and that public taste and exhibitors' vagaries have much to do with the degree of appreciation that is bestowed upon even the most promising novelties. C. H. P.

NEW JAPANESE CHRYSANTHEMUMS.

NOVELTIES are more numerous this season than usual. Although from the lists that have been published from time to time during the flowering season the different floral committees may appear to have been somewhat lavish in the making of their awards, this is not so. Novelties must possess much that is attractive in addition to certain essential points of quality if they are to be recognised with an award of merit or a first-class certificate. As raisers know only too well, many excellent seedlings and sports have been passed over for some good reason. The standard of quality is now much higher than it was a year or two since, and the raising of the standard is undoubtedly a step in the right direction. Varieties that are worthy of note and that may supplement those referred to in THE GARDEN of October 29 last are the following:

Mrs. A. H. Lee.—This is a seedling submitted to the National Chrysanthemum Society's committee by Mr. N. Molyneux of Rookesbury Park Gardens. When compared with other Japanese of a crimson colour this handsome exhibition flower stands pre-eminent. Rich crimson, with golden reverse, is a proper description of its colour, and the flowers are large and spreading. The Japanese bloom of the present season exceeds in beauty that of *Mrs. Chas. Davis*. The glorious orange-yellow colour is most effective, and the flower is also very elegant. Mr. Norman Davis staged six blooms at the Crystal Palace at the National Chrysanthemum Society's November show. This variety is the result of a cross between *Duchess of Sutherland* and *J. R. Upton*, two well-known exhibition flowers. A Japanese flower of ideal form is that of

Mrs. A. T. Miller.—This is a pure white seedling from the popular variety *Miss Olive Miller*, having broad, curling petals. For exhibition the flowers should be in demand, as the form is really charming. Long petals of medium width build a reflexed bloom of drooping form, and the colour is mauve-pink on a white ground. The last two varieties were raised by Mr. George Mileham, Leatherhead, who has been very successful in recent years. Another Japanese bloom of good form and solid build is

W. A. Hetherington.—In this case the petals are long, and broad also. The colour may be described as rosy mauve, with a white centre. Mr. N. Molyneux has also given us another very fine flower in

Mrs. T. Dalton.—This variety came before the National Chrysanthemum Society's floral committee on the 21st ult., and received the coveted first-class certificate. It is a large flower of Japanese reflexed form, having fairly long petals of medium width. The colour may be described as rosy crimson, with a bronzy buff reverse, and is one that should find ready acceptance. Another promising crimson sort from the same raiser is

Mrs. A. Arnold.—This flower lost somewhat by being staged with the blooms of *Mrs. A. H. Lee*. A grand pale yellow Japanese named *Mrs. E. Crossley* is an exhibition flower of considerable promise. The petals are broad, twisting and curling, 8 inches in breadth, and 8 inches deep.

Josephine Rousset is a most effective flower of a lovely rosy amaranth colour, and a distinctly beautiful shade of these colours, too. The form of the flower may be accurately described as Japanese reflexed, and, though not so large as some others, it is quite large enough. This is one of the best of the continental introductions. A creamy white seedling of great promise is

Mrs. W. Elliot.—The petals are prettily twisted and curling, and, together with a primrose-coloured centre, make a refined exhibition bloom. A plant of a dwarf kind is the new

Lady Lennard.—This is a good plant for grouping, and at the same time develops good exhibition Japanese blooms of a pleasing incurved character; large, full flower of a terra-cotta bronze colour.

President Viger.—Although not so new as the others this deserves special mention. Mr. F. S. Vallis in his superb display at Sheffield staged three blooms in the vase class in better condition than it has ever been seen before. The blooms were large, and the broad petals were a bright purplish rose, with silvery white reverse in colour. The glorious yellow *Beauty of Leigh* is now a favourite, although it is so tall. Mr. Norman Davis had this very beautiful at the Crystal Palace.

A Keston seedling is *Mrs. R. C. Pulling*. This is a refined flower, with long, drooping florets of medium width, making a handsome exhibition specimen; colour rosy violet on white ground, with primrose centre. There are several other sorts, of which a review must appear at a later date.

THE "RUNDLE" FAMILY OF INCURVED BLOOMS.

THE National and other large metropolitan Chrysanthemum societies seem to forget that there are many pleasing types of the "Autumn Queen" that are seldom or never seen at their shows. Quite recently, when at Sheffield, I was struck with the

charm of a display made in a class for six blooms of the Rundle family. This family of the incurved type of the Chrysanthemum is represented by *Mrs. George Rundle*, white; *Mr. George Glenny*, primrose; and *Mrs. Dixon*, golden-yellow. The blooms are typical of what an incurved Chrysanthemum should be, and have a peculiar charm. They are of small to medium size, and in ordinary competitions are completely ousted because of their want of size. For this reason the Sheffield Chrysanthemum Society wisely provide a class for two blooms each of the three varieties above referred to, and this competition is confined to the members known as cottagers. The flowers have to be staged with at least 7 inches and not more than 9 inches of stem on show-boards covered with moss, and the effect is very pretty. At the show held on the 11th and 12th ult. there were no less than fifteen competitors in this class, and the display they made was one to be remembered. Eight prizes are offered in this one class, and to discriminate between the respective merits of the exhibits is no easy matter. Beautifully finished, even blooms of good quality led the van, well deserving the premier award. At the expense of sacrificing some of the classes for the larger blooms, which are much overdone, such competitions might be encouraged with advantage to the individuals as well as to the show itself. The decorative aspect of the Chrysanthemum as showing its general utility for house decoration and other purposes should surely be one of the primary objects of all societies.

D. B. CRANE.

NOTES FROM SCOTLAND.

THE GLASGOW PARKS.

WHATEVER season one may visit those Glasgow parks in which there are extensive glass structures one is certain to find much to interest the horticulturist. This winter there is no falling off, but rather an increase in plant attractions. New plants are added as opportunity offers, and the many specimens increase yearly in size and effect. A few notes at the present time may be acceptable.

QUEEN'S PARK.—In this, one of the finest of the Glasgow parks, there is a constant succession of flowers. From early in autumn until Christmas a Chrysanthemum display is provided, and this year the flowers have been excellent. In one of the houses there were about 4,000 large blooms. The varieties comprised the best of the older well proved ones, with a good selection of the more recent additions. A number of plants are also grown in a more natural way, i.e., without disbudbing. Unfortunately, the dense fogs with which Glasgow is afflicted are injurious to the *Cattleyas* and *Lælias*, but *Cypripediums*, *Odontoglossums*, *Masdevallias*, and *Dendrobiums* are all cultivated successfully. The useful *Cypripedium insigne* is extensively grown, and in the other parks there are many good forms. There is a large collection of *Odontoglossums*, and some of the best forms of *O. crispum* are cultivated. *Masdevallias* are also well grown, and good pans of *M. tovarensis* are very fine. I observed, also, good plants of *Stenoglottis longifolia*, an Orchid remarkably easily grown in a cool house. A good display is maintained by zonal *Pelargonium*, grown for winter flowering, but the fog is very injurious to these at times. There are also many other winter flowers to succeed some of the above, *Kalanchoe flammea*, *Monochætum ensiferum*, *Ruellia macrantha*, and many others. Greenhouse *Rhododendrons* are largely cultivated here, and are showing well for bloom. Foliage plants, such as *Alocasias*, *Dracænas*, *Palms*, *Ferns*, and many others are always attractive, and a number of good seedling *Anthuriums* are coming on rapidly. Mr. M'iver deserves much credit for his work here.

TOLL CROSS PARK.—Mr. Wilson, another good plantsman, is in charge of this park, and the houses are always bright and repay a visit. Considerably less extensive than those at Queen's Park, they are no less interesting. Here Chrysanthemums, both large-flowered and decorative, are largely used, and

a long succession is maintained. Those with large blooms are well grown, and tops are struck in considerable numbers to suit the stages. Such single Chrysanthemums as Miss Rose are well grown.

Zonal Pelargoniums, as at the Queen's Park, are found very valuable, despite the effects of the fog. There are also hatches of *Cineraria Mootei*, and *C. stellata*, which seem to be well cultivated at Tollcross. The winter-flowering *Begonia* is well represented. The variety *Caledonia* has had to be discarded owing to its want of vigour, but there were many splendid plants of *Gloire de Lorraine*; Turnford Hall, which is considered here the same as *alba grandiflora*, and the *Rothschild* variety. The latter has larger flowers, but is not so bright as the typical *Gloire de Lorraine*. *Primula sinensis*, both the large flowered and the stellata sections, and a fine strain of *P. obconica* are largely and well cultivated. A number of seedling Orchids of various classes have been raised and form a most interesting study. Among them I observed a nice lot of *Cattleyas*, *Lycaste Uroskinneri*, a fine lot of *Odontoglossums*, many good *Cypripediums*, *Lalias*, *Oncidium*s, and *Masdevallias*. Among the hybrid *Cypripedium*s raised here is one named *Baillie W. F. Anderson*, in honour of one of the civic dignitaries. The foliage plants are always good, and *Ferns*, *Palms*, and others are admirably done.

SPRINGEURN PARK.—The winter garden here is an excellent one, and a gallery in the centre of the houses provides a useful feature. Since Mr. Thomson, formerly gardener at Philphead, took charge many improvements have been made, and it can now be said to be in line with the others under the direction of Mr. James Whitton, the superintendent of the Glasgow parks. A great improvement has been the planting out of a number of fine specimen *Camellias* in the central house. These are much appreciated. The whole effect of this house as seen from the gallery is very fine. The galleries are surrounded by stages on which are *Primulas*, zonal *Pelargoniums*, *Marguerite Carnations*, and winter-flowering *Begonias*, all admirably grown. There is a remarkably well-kept Fern house, where large plants are planted out and intermingled with *Rex Begonias* and other suitable plants. Orchids are well grown, while succulents and a varied collection of interesting plants of all kinds appeal to the tastes of every one. The *Chrysanthemums* here have been very fine.

THE BOTANIC GARDENS.—The improvement effected here since this establishment also passed under the control of Mr. Whitton still continues. Among the most recent improvements is the construction and planting of a somewhat extensive range of rockeries. In the course of a little time this should be a great attraction to these gardens. In the Kibble Palace, one of the features of the Botanic Gardens, the group of tree and other *Ferns* in the centre of the main building has grown vastly in beauty recently. There is a house devoted to Mosses, filmy *Ferns*, and *Selaginellas*. It has been entirely remodelled in a natural way. There is a remarkable collection of native Mosses, collected by the propagator Mr. Scott, who has made a special study of them. Space will not permit of further detail at present of the many good features of this establishment; but I may remark that the Orchids are finer than the writer has ever seen them here before, after an acquaintance with the place for many years. S. A.

THE FLOWER GARDEN.

PAMPAS GRASS (*GYNERIUM ARGENTEUM*)

FROM the South American plains comes the noble Pampas Grass, which is hardy in most parts of England. The grand tufts of foliage and immense feathery blooms have long been well known and largely used in our gardens and other grounds. The plant is dioecious—that is to say, the male and female flowers are borne on different plants. They vary a good deal from seed, some having much more fully furnished plumes; they also vary a good deal in

and others are beautiful flowers, and their want of scent is to a large extent made up by their long stem and rich, clear colouring. The variety *Lizzie McGowan*, of which we give an illustration, is a good free-flowering white *Carnation*, an American introduction. Hundreds of thousands of these *Carnations* are now grown for market, and one sees them in all florists' shops. The old varieties of Tree *Carnations* seem to have been altogether ousted by the newer sorts.

MONTBRETIAS.

THOSE who desire a fine display of these indispensable garden flowers next year should not longer delay planting. While they are not very exacting, there are one or two items quite worth attention. New, that is, freshly imported stock, provided always that the plants were properly harvested, may be planted over a somewhat lengthened period because of the check already afforded in the process of lifting. Much of the growth in the first year and, of course, the ultimate success of the plants depends upon the harvesting of the stock, and if the work is performed too late the new growths or shoots will be already piercing the soil. Such as these require more than ordinary care in replanting. On the other hand, when the new corms are more or less intact the planting season may be extended considerably. There is naturally some difference in the corms of these *Montbretias*, and not a little also in the time of their starting into growth. The new and charming *M. rosea* is quite distinct in corm, and is more like a small *Gладиолус* bulb. Such sorts as this take less harm when kept out of the ground, and the same remark applies to any variety that has not greatly extended its underground shoots.

It is another matter when dealing with the established clumps in the garden. These should be lifted where necessary, separated, and replanted at once. Too frequently a very indifferent method of planting is adopted simply because it is convenient—I mean taking a handful and planting them in a lump. Not only is this not a good way, but it is not likely to give good or even satisfactory results. These *Montbretias* cluster together naturally in the garden, and the planter in the beginning should have this in mind. Having well dug and prepared the ground, he should plant in the following way: Suppose, for example, a collection is being put in, say, a dozen of each kind. Each lot should be planted over a ground area of 15 inches or 18 inches, and if rather thin-looking in the first year the gain will be obvious later on, or he may dig out the soil 6 inches or 8 inches deep all over the area named. Next turn up and manure the lower soil. Level the soil, and then lay in the corms with runners intact. In heavy soils a good sprinkling of sand may be given to each lot before covering in. At the depth named the roots will be safe, and in course of time make a fine display. Deep and rather rich soil, with ample summer moisture, is what these showy plants prefer. E. J.

FLOWERS (REDUCED) OF THE AMERICAN CARNATION LIZZIE MCGOWAN.

colour, some being of the usual warm white, while others are tinted with rose colour or faint purple. It is better, therefore, in setting up a stock to see them in bloom in the nursery so as to make sure of having a good strain.

R. DRAPER.

Seaham Hall Gardens, Durham.

CARNATION LIZZIE MCGOWAN.

IT is surprising how popular the American winter-flowering *Carnations* have become during the last few years; they have taken the market by storm. Such sorts as Mrs. Lawson, *Enchantress*, *Fair Maid*, *Royalty*,

Auricula Henry Wilson. This is a fine green-edged variety raised by Mr. B. Simonite of Sheffield, and it was finely shown at the Midland Auricula Society's show at

Birmingham in 1903, when it was selected as the premier edged flower. It has a brilliant green edge, golden tube, and fine smooth paste, the pip stout and finely formed. It is being put into circulation at a high price, but not higher than its merits demand. R. D.

AURICULA ALPINE THETIS.

THIS is considered to be by some experts the best light centred alpine in cultivation. In the case of the show Auriculas there is, forming a zone round the tube, a circle of meal, over which is laid a delicate white farina, which will adhere to the finger when slightly touched by it. It is this peculiarity in particular which differentiates the show from the alpine Auricula. The presence of paste on the zone of colour, whether white, cream, or yellow, of the alpine Auricula is a weakness; there is no farina whatever on the centre of an alpine Auricula, if there were it would not be a true alpine. Nor is the tube considered, as in the case of the show type, but the stamens should fill up the throat of the flower, hiding the pistil from view. Thetis has a creamy white centre, and the shading on the margin salmon flushed with violet, and shading to deep purple. It is fairly prolific in offsets, but at present plants of it are very scarce. R. D.

CESTRUM AURANTIACUM.

LIKE many other greenhouse plants this evergreen shrub is most useful for summer bedding purposes. Cuttings inserted in August quickly root, and if

the plants can be kept gently growing throughout the winter they will be fit for use during the following summer. An occasional pinching will induce bushy growth. Lightly tied plants of pillar shape when used as "dot" plants supply an uncommon shade of orange, which can be effectively blended with most other colours. *Cestrum aurantiacum* may be described as an orange *Habrothamnus*; it is a good companion for the well-known *Habrothamnus elegans* (by some authorities included under *Cestrum*) for clothing the walls or pillars of cool greenhouses. When so used they should be planted out in a rich light soil and be copiously watered during the growing season. So treated it will grow freely and flower profusely. The flowers last well in a cut state, and, although scentless by day, they are very fragrant after dusk.

Bodmin.

A. C. BARTLETT.

THE ROSE GARDEN.

THE GARLAND ROSE.

AMONG the many ways of worthily using the free Ayrshire Roses, one of the best is to leave them to their own way of growth, without any staking or guiding whatever. Due space must be allowed for their full size, which will be a diameter of some 10 feet. Of these useful garden Roses none is more beautiful than the Garland, with its masses of

pretty blush-white bloom. It is well worth getting up at 4 a.m. on a mid-June morning to see the tender loveliness of the newly opening buds; for, beautiful though they are at noon, they are better still when just awaking after the refreshing influence of the short summer night.

Several others among the old Ayrshires are excellent in this way of growth, though perhaps there are none to beat the Garland and Dundee Rambler. A grassy space where they may be seen all round, or a place where the great bush may be free at least on two sides, is the most suitable, or they may be used as central or symmetrically recurring points in a Rose garden of some size. The young growths that show above the mass when the bloom is waning are the flowering branches of next year; they will arch over and bear the clusters of flowers on short stems thrown out at each joint. The way these young main branches spring up and bend over when mature is exactly the way that best displays the bloom. Each little flower of the cluster is shown in just the most beautiful way; and it is charming to see, when light winds are about, how the ends of the sprays, slightly stirred by the active air, make pretty curtsying movements arising from the weight of the crowded bloom and the elasticity of the supporting stem.

There is a whole range of use of these beautiful Roses, from this free fountain shape without

THE GARLAND ROSE OVER WALL.

any artificial support, to association with trees and bushes in shrub clumps and wood edges, and from that to clambering into the trees themselves.

Everything that has been said of the Garland Rose, as to its use as a fountain Rose or free climber, may also be said of Dundee Rambler, Bennett's Seedling, Felicite Perpetue, and others of the cluster Roses classed as Ayrshires. They are all worthy of use in these ways, and of being encouraged to clamber into trees and hedges. One cannot help observing how the support of a tree encourages almost abnormal growth. The wild Dog Rose will go up 20 feet, and Sweetbrier nearly as high; while almost any Rose that has at all a climbing habit will exert itself to the utmost to get high up into the tree.

ROSES ON A CHALKY SOIL.

I HAVE received a letter from "W. R. H." on this subject. It is well understood by Rose growers that a certain amount of chalk or lime in the soil is essential to the perfect cultivation of the flower. Indeed, many growers go to great trouble to obtain chalk in order to improve and sweeten and render more fertile the strog clayey soils of the country. When we remember that chalk provides a real plant food, and that it serves to counteract sourness in over-manured soils, we can readily understand that it is valued by the cultivator. But, of course, there is such a thing as having a soil in which chalk abounds in too large a proportion. It then becomes a question how to improve it.

The celebrated Rose garden of Mr. A. Tate, Downside, Leatherhead, is a splendid example of how far a chalky soil may be improved in order to cultivate good Roses. Here it was found necessary to remove the pure chalk, which in places came close to the surface, and replace it with imported clayey loam. I well remember visiting Downside, and was struck with the vigour of some Lime trees which I saw rooting into the pure chalk. Although it was found advisable to improve the Rose beds by adding loam, yet here was evidence that trees would grow even in the pure chalk.

I would strongly advise anyone with a chalky soil, who desires to grow good Roses, to add turfy loam to the beds or borders, mingling this with about equal parts of the natural soil, and at the same time to use cow manure freely, especially to the lower stratum of soil, say about 2 feet 6 inches beneath the surface. As a number of Roses may be grown in quite a moderate-sized bed, such preparation should not entail much outlay, and the value would be returned handsomely in beautiful Roses. To grow good Roses upon a chalky soil the plants should be budded upon a stock that is inclined to be surface rooting rather than penetrating. It is not at all necessary for the roots of Roses to run down deeply, providing they obtain the necessary food near the surface. American gardeners grow Roses under glass on benches in just a few inches of soil, but then the plants are upon their own roots, and the soil is well enriched with bone-meal.

The ideal Rose plant for a chalky soil would be that on its own roots. Such plants produce abundance of fine roots that may be kept near the surface by a system of mulching during the summer months; but as own-root plants are not readily procurable, the next best are those upon short standard Briars and Briar cuttings. In many sea-side gardens that I have seen where chalk abounds, I have invariably found the hedge Briar making splendid growth, especially when budded with Tea Roses. You say some individuals have recommended you the Manetti stock for Tea Roses. I would advise you to have nothing to do with this stock for this class, and even for Hybrid Perpetuals and Hybrid Teas I think you would do well to avoid it if you can obtain what you want on the cutting Briar.

Some Roses make better growth upon the Manetti stock, for instance, Ulster and Papa Lambert; but the true Teas should not be budded on Manetti, at

least that is my experience. Then, again, Roses upon this stock are so susceptible to Orange fungus and red rust, and in August, when plants on the Briar are beautiful in their lusty vigorous foliage, those on the Manetti are often shedding theirs.

The De la Grifferaie stock is useless where quality of blossom is desired. One may obtain big plants upon this stock, but of what use is that if there be no corresponding quality. For ordinary deep soils nothing can surpass the seedling Briar, but I repeat, upon shallow and chalky soils the Briar cutting and the hedge Briar are the best stocks for Tea Roses. There are three essential facts to remember by all who grow Roses upon chalky soils, namely, frequent transplanting, mulching, and watering. By transplanting the Roses in October every three or four years, renewing the beds and adding manure, the plants may be kept in a healthy condition for many years, even though the soil be shallow and chalky.

I would advise winter mulching, carefully digging this in in March. Then in May, when roots are very active, another mulch may be afforded. As to varieties those Tea Roses whose foliage are most persistent are the best for the garden. If you desire to have real good decorative masses for autumnal effect plant such sorts as Mme. Antoine Mari, Peace, G. Nabonnand, Sulphurea, Corallina, Marie d'Orleans, Marie van Houtte, and others; not forgetting the beautiful Hybrid Teas Mme. Ravary, Liberty, that queen of Roses Mme. Abel Chatenay, the grand new Pharisæer, Antoine Rivoire, and hosts of others.

CRIMSON RAMBLER ROSE.

IN reference to this Rose (page 295) I may say it disappoints many because it only flowers to perfection on the wood of the previous year. A plant here on a trellis throws up yearly, in spring, five or six strong shoots, from 15 feet to 20 feet long, which the following year are a mass of bloom. The old shoots are cut down to the base in November. When one or more old ones have been left they have scarcely flowered, and only break into small shoots for next year. Another plant, which is nailed to the house wall and cannot be cut down, scarcely blooms at all, and throws out no base shoots. It remains, as the few flowers it produces look well amid a rampant Brunonis, as both Roses flower exactly at the same time. Aglaia is quite different, and flowers on all wood without pruning.

Reigate.

J. R. D.

COLOUR IN THE MIXED BORDER.—VII.

(Continued from page 382.)

NOW for the annuals. There is *Anagallis rubra grandiflora*, which is a *l'impernel*, and as such an early closer; *Linum grandiflorum rubrum*, which is a charming annual, and will flower for you all the summer through; crimson *Jacobaea*, *Hawkweed*, *Godetia Lady Albemarle*, dwarf *Dianthus chinensis*, and Sutton's crimson *Clarkia*. *Love-lies-bleeding* (*Amaranthus caudatus*) is so effective that it should be more grown than it is; it makes, too, a very handsome pot plant for winter flowering. There are a few words to be said about this somewhat strange flower which may be of interest. Its name of *Love-lies-bleeding* has been evolved from the first part of the word *Amaranthus*, which means unfading. The French call the flower *Discipline des Religieuses*, or the Nun's Whipping-rope, which is very different from its romantic English designation.

Love-lies-bleeding must be sown in March on a hot-bed, and planted out in May. A. *speciosus* is a still finer sort. We can find a few more red annuals, *Coreopsis atrosanguinea* and *Malope*, Sutton's improved *Ruby King Nasturtium*, a dwarf variety for the fore-

ground, and a deep crimson *Phlox Drummondii*. I am sure there are several other red annuals that might be well added to this list, and I fear, in looking through the whole series of these articles, that there have been one or two omissions. In the article of the 12th inst., when dealing with the pink section, *Phloxes* were not mentioned, and though it is true that most pink *Phloxes* have that lilac tone that I deprecate, still I think *Beranger*, which is only 3 feet high, might be very useful towards the centre, and so would *Ferdinand Cortez*, still further forward. And now, before I conclude this series of articles, I should like to add a few words on a very important subject. It is the art of tying and staking, practically and thoroughly, without destroying the artistic and natural effect of the border, and this of all gardening operations is the most difficult to do well. The fault often is that the staking is not done when the plant is young and pliable enough to be trained, and in consequence it has been allowed to grow crooked and lopsided before its training begins.

To remedy this often necessitates the loss of several limbs or branches, a waste that might be avoided by the "tie in time that saves nine." This is particularly the case with *Gaillardias*; they sprawl about in a most aggravating way if they are not trained from the first appearance of their flowering stems. Again, with *Delphiniums* you have no idea what a difference it makes if you put in your sticks in April when the growth is tender, and tie up each stem carefully. By the time the *Delphinium* has grown to its appointed height the sticks will be entirely concealed by the foliage, and a beautiful symmetrical plant bearing flowers on each straight spike will be an ornament to your border. Another advantage of staking *Delphiniums* thus early is the possibility of protecting them from the rigours of spring frosts, for a little hay is easily put inside the stakes, and this will avert a danger to which the young growth is extremely susceptible.

The same treatment holds good with the *Oriental Poppies*. If they are not supported they often break down disastrously with the weight of their great gorgeous blossom when wind or rain assails them during their flowering period. The best stakes to use are well-trimmed Deal sticks painted green; *Bamboos*, which have the merit of being light and cheap, are not really practical, for owing to their being round they are apt to work loose in a soil that is not very tenacious, and the result may be foreseen. If money is an object, and it generally is, for enthusiastic gardeners are usually extravagant, you can buy your stakes unpainted, and on wet or winter days you can paint them yourself, or make your garden boy do so; they then will cost a third of the others. You will want three different sizes, for many small plants must be kept off the ground, if they are not pegged down. *Salpiglossis*, that handsome annual, requires a thin Hazel wand to support its charming vari-coloured flowers, and for still smaller things pull a Birch broom to pieces and use the twigs. All this is very troublesome, I allow, but good gardening is extremely finicking work, and it is only done properly when the heart is in it. It is no use bunching up your plants and binding them together with a bit of raffia into an inartistic floral bundle. You must tie each spray apart conscientiously on its stick or twig, and it will take you hours, but in the end you will be repaid. The charming subdued green *Raffiatape* (West's Patent) can now be got from all seedsmen. Its cost is only 1s. 6d. for 250 yards, and it can be used with great advantage in the front of your borders, and for plants in your rooms.

I think some clever head might design some simple plan for staking Sweet Peas in clumps.

I will now bring this series of articles to a conclusion. I feel I have made many omissions, but it is a subject full of difficulties and complications. The following words from the mouth of a great professional grower of herbaceous plants will endorse this: "I have found colour sections rather difficult to manage owing to lack of some colours at certain times, and an over-abundance of others at the same period of flowering. I like the carpeting idea amongst the taller plants, and if care is used in selection a greater continuance of flowering can be obtained, but then again colour blocks are difficult to adjust."

AUGUSTA DE LACY LACY.

A GENERAL CALENDAR.

HALF-HARDY BULBS, as Montbretias and Ixias, should be heavily mulched with leaves, and a little Bracken sprinkled over the leaves to prevent their being blown about with the first high wind.

CHINA ROSES.—The pink monthly Rose is the one best known, never failing to give us the earliest and latest bunch of Rose buds; and, besides this, there are many other varieties of vivid colouring—crimson, carmine, and rose, and some with a blue metallic lustre in their leaves, which is lovely in itself. These Roses are not only almost always in bloom, but they possess a power of endurance which does not belong to the hybrid varieties. We have now a fine old plant known to have been planted half a century ago from which I am gathering handfuls of buds. They do not require such gross feeding as other Roses, and thus are more useful for permanent beds; among them spring bulbs can be planted with success.

TRANSPLANTING TREES.—These severe weather experienced the latter part of last month greatly retarded this important work, and the soil will not now be in such good condition as it was before the heavy fall of snow, hence great care must be exercised if success is to be secured. Filling in the soil at transplanting is a very important matter. Spread the roots out on the prepared bed, which should not be hard and impervious subsoil, but a bed of prepared compost, into which the roots may penetrate and find nourishment. In filling in the soil avoid the absurd, although very general practice, of moving the tree backwards and forwards to get the soil down among the roots. Treading the soil about the roots of trees at transplanting is a dangerous operation. The soil should be carefully worked in about the roots by the hand or with a blunt stick, for the pressure of the foot, unless carefully applied, is apt to break off the principal roots unobserved.

PROTECTING EVERGREENS FROM WIND.—Of all trees and shrubs requiring protection from wind, none need it more than evergreens recently planted; they are liable to be blown about, and when this is not guarded against the young roots are prevented from taking hold of the soil, and the mass of roots and soil becomes separated from the surrounding earth. Interstices are formed into which rain first and frost afterwards enter, both equally injurious to the young and tender fibres, while in spring the parching winds penetrate.

PROTECTION OF CELERY.—I find the best plan in severe weather, when there is no covering of snow, is to place some dry litter or Bracken Fern along the sides of the rows, and then shake a little

more loosely on the top. Avoid a heavy covering, it only becomes a wet and sodden mass, and the Celery suffers accordingly. Damp is its worst enemy. Whatever form of protection is used, it must be arranged that light and air can have free access.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

ORIGIN OF THE NANKEEN LILY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Knowing the interest that is attached to the origin of this Lily induces me to send a short account of some experiments carried out here many years since with the special object of deciding this point. It naturally occurred to me that if this pretty Lily is really a hybrid from *L. candidum* and *L. chalcedonicum*, it might be possible to raise it afresh by cross-fertilising these two forms. Accordingly, in August, 1880, *L.*

as in the scarlet Turk's-cap Lily. This is a very distinct and handsome Lily. Still later in flowering were three or four of the seedlings, which, both in growth and habit, were like *L. chalcedonicum*; but the flowers were much paler, and more of a brick-dust colour, altogether lacking the brilliant sealing-wax vermillion of the parent.

These seedlings are in every way inferior to *L. chalcedonicum*, and have nothing to recommend them beyond the history attached to their origin. I may add that every year since 1895 these Lilies have flowered regularly, and keep to the same time in sequence of flowering. The variety A, which resembles *L. testaceum*, is always the first, then follows B, the apricot-coloured one, and lastly C, the brick-dust section, opening their flowers a few days before examples of *L. chalcedonicum*, in other parts of the garden, are out.

There are now good clumps of each of these three forms, and should any of your readers be in this neighbourhood next August they are welcome to see in the garden the result of this experiment, which has left no doubt in my mind that the ordinary *L. testaceum* is a hybrid Lily which has arisen from crossing the old Madonna Lily with the pollen of *L. chalcedonicum*, and was probably

A GROUP OF LILIUM TESTACEUM.

candidum was fertilised with the pollen of *L. chalcedonicum*, and also *L. chalcedonicum* with pollen from *L. candidum*; but alas! no seed resulted. The following year was wet and unfavourable, but in 1882 I was fortunate in getting seed from one pod of *L. chalcedonicum*, which had been fertilised with pollen from *L. candidum*. The seed thus obtained was sown in a shallow pan and left alone for two years. In October, 1884, the seed pan was turned out, and the small bulbs, some nearly as large as a Hazel Nut, were planted out in a dwarf Rose bed and left to take care of themselves. They grew slowly, and I began to wonder whether they would ever flower. At last, however, my patience was rewarded, and on August 7, 1895, the first flower opened. It proved in point of colour an exact counterpart of the ordinary *L. testaceum*, but the petals were not quite so long or twisted; in fact, they curled back more like the ordinary form of Turk's-cap Lily. A week later another of the seedlings flowered; this proved quite different in colour, a warm apricot tint, without any spots, having the petals not so tightly recurved

produced in some districts where the beautiful white Lily is sufficiently happy to form seed, which, as far as my experience goes, is never the case in this neighbourhood.

Salisbury.

H. P. BLACKMORE.

SHRUBS OR HERBACEOUS PLANTS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The question whether *Phygelius capensis* is a shrub or a herbaceous plant (page 369) well illustrates the difficulties that beset us when we endeavour to tie down Nature to any hard and fast line. Though referred to in the "Dictionary of Gardening" as a shrub, on the other hand it is placed in the "Kew Hand List of Herbaceous Plants," and not among the shrubs, thus proving that authorities are by no means agreed on the point. A greater puzzle than this is to be found in *Coriaria terminalis*, recently given an award of merit by the Royal Horticultural Society. This is included both in the "Hand List of Shrubs" and of herbaceous plants, so that in this instance it is

certainly a case of pleasing one's self. That beautiful autumn-flowering subject *Lespedeza Sieboldi*, better known as *Desmodium penduliflorum*, which was a short time since alluded to in *THE GARDEN*, dies down annually so near to the ground level that exception might be taken to classing it with the shrubs. Many tropical plants, again, such as some of the *Eranthemums*, *Aphelandras*, *Begonias*, and numerous others do not die down, hence they cannot be considered herbaceous, while, on the other hand, they are not of a woody nature. The expressive title of sub-shrub is sometimes applied to such as these.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Mr. Molyneux's note on page 369 as to whether *Phygelius capensis* should be shown in classes for hardy herbaceous plants reveals one of the many perplexities exhibitors endure at shows. Personally I should agree with the judges and admit the exhibit. Many herbaceous plants become woody with age and flower from old wood quite freely. *Phlomis* and the Japanese *Dracocephalum* are instances that occur to mind at the moment. One can be too fastidious in such matters; plants that make permanent woody stems in mild countries may die to the ground level in colder districts, and yearly records also vary with individual plants. One of the safest guides I know that would help exhibitors is the "Kew Hand List of Herbaceous Plants." Its price is small, and with a copy of this handy the exhibitor can soon set matters right. If that fails, where is the higher court? Not in one individual, surely! I have witnessed many heated discussions as to what can be defined by "perennial." The meaning of the word is, of course, obvious; yet many societies (and, I believe, the premier one) cite, in their schedules, *Pentstemons* as typical instances of biennials, and therefore must not be shown as perennials—a ruling hopelessly inconsistent with the fact that more than half the *Pentstemons* known to cultivation are perennial. G. B. M.

POTATOES TO EAT AND THE NATIONAL POTATO SOCIETY.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Having read the correspondence in *THE GARDEN* on the above subject, I notice that the Rev. G. H. Engleheart complains that "those who reported the National Potato show mentioned so little about the cooked Potato class," and, after condemning such varieties as Sir John Llewelyn and Up-to-Date as being only fit for not very discriminating cattle, your correspondent goes on to say: "Think of judging our fruits and vegetables, as we habitually do, by the eye and not by the mouth." Now surely the National Potato show was held—as I take it all horticultural shows are held—for the purpose of showing the cultural skill of the exhibitor; and in what other way can this be done than by exhibiting them as at the recent show. Surely Mr. Engleheart does not want to turn our horticultural shows into cookery exhibitions. Perhaps he may be surprised to learn that if Potatoes were awarded prizes only after a cooking test it would be quite as misleading to the public as the present system, because soil and situation have much to do with the quality. A variety that cooks well from one soil may be quite uneatable from another. Even in fields and gardens adjoining they are often quite different. For instance, in this district Potatoes planted in March and April were checked by the drought in June and the early part of July. When rain came they made a second growth, which, of course, spoilt the quality, whereas those planted at the end of June made one growth, and are consequently of much better flavour. A crop of Kerr's Cigarette I recently lifted that were planted after midsummer fully confirms this. I do not by any means suggest that the planting of Potatoes should be deferred until midsummer. I mention this to show that many things may occur during the growth of Potatoes to alter their quality. I quite agree with Mr. Engleheart that the Ashleaf for flavour is unbeatable, as are many yellow-fleshed varieties,

but the public will not have them after August, so it is perhaps, as Mr. Engleheart says, the grower for market that one has to consider. There are many of the whiter-fleshed varieties that are worthy to rank as good-flavoured Potatoes, such as Kerr's Lord Dundonald, Kerr's Cigarette, The Factor, and the Up-to-Date I think Mr. Engleheart would say were good if I sent him some. (I enclose a few, Mr. Editor, for you to try.)

With regard to judging Potatoes at the National Potato show, I should certainly say size should be a last consideration, and that the awards should be made in favour of clean, healthy, shapely tubers of uniform size. We may safely leave the matter of quality when cooked to the public; the bad ones will soon die a natural death, and the good ones will be in demand whether boomed or not.

J. H. RIDGEWELL.

The Gardens, near Histon, Cambs.

[We thank our correspondent for his interesting letter. The Potatoes sent were of excellent flavour, but this is so much a matter of where they have been grown that really no hard and fast rule can be drawn. As Mr. Ridgewell says, it is a matter largely of soil, and this we have proved in our garden this year, but the great point insisted upon by Mr. Engleheart is that size and shape are

CARNATION WHITE STAR (REDUCED).

placed by the judges at horticultural shows before flavour or "quality." This should not be. We have the greatest sympathy with Mr. Engleheart's efforts to educate the public to the proper qualities of the produce which it consumes. Flavour—which means, of course, wholesomeness—must come before mere bulk.—Ed.]

[TO THE EDITOR OF "THE GARDEN."]

SIR,—With respect to the discussion in *THE GARDEN* regarding the eating qualities of Potatoes I am not quite clear as to whether Mr. G. H. Engleheart wishes to condemn all the new varieties as being of inferior flavour. If such is the case, then I can only conclude that either palates must differ or else Potatoes vary considerably in flavour when grown on different soils. The other day I had the privilege of tasting a boiled tuber of Northern Star, grown in a little village on the Cotswold Hills, and I wish for nothing better. I also know that Discovery is a good eating Potato, as also are The Factor, The Crofter, and Cigarette, and these are all new. Like your correspondent, I know nothing of the flavour of Eldorado, which is not surprising, as it is hardly to be expected that a man who is

merely human would boil a tuber that he could readily dispose of for a couple of guineas or more. On the whole, however, I do not think that there is any marked deterioration in the quality of Potatoes with the introduction of modern varieties.

G. H. H.

THE GARDENERS' ORPHAN FUND.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In common doubtless with many other subscribers an appeal has reached me from the Rev. J. Sutherland, Wroxton, on behalf of the widow of the late Mr. John Hogan, late head gardener at Wroxton Abbey, who died on October 20 last after a brief illness, leaving a widow and six young children. This is indeed a sad case, and, although I have never favoured the election of two children from the same family at once, yet I have no knowledge of a case so sad as this one, and it would be indeed hard to withhold from these poor fatherless little ones the full 10s. per week which the election of two of them on to the Orphan Fund would give. But may I not use this most distressing case as a lever with which to appeal to not less than 1,000 more fortunate gardeners than the late Mr. Hogan, and who have not before subscribed, to send to the secretary at least 5s., and thus make these children's election sure.

A. DEAN.

CARNATION WHITE STAR.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I can recommend this as a good Carnation for the town garden, that is if the flowers are wanted only for cutting or to make a display in the garden. They are not large, but they are very attractive, are freely produced, and last a long time. Of course, a white Carnation is sooner disfigured by the weather than a coloured one, but White Star seems to be particularly sturdy and well able to take care of itself.

Berley.

G. H. DOVER.

STAGING LARGE FLOWERS OF CHRYSANTHEMUMS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—With every desire to see large blooms of Japanese Chrysanthemums exhibited at shows in the most effective way, I could not admire the method I saw recently at Sutton, Surrey, where the flowers in several classes have to be set up in drain-pipes some 20 inches long. The base or flange ends of these pipes are filled with cement and painted dull green outside. The mouths are some 3 inches in diameter, and when erect the stems hold water. In these six blooms are placed in each, the flowers being on fairly long stems. Because they are tall when erect these pipes have to be stood on the floor, and when some two or three dozen are in double or treble rows, no foliage being used to drape the naked pipes, the effect is far from pleasing. Certainly to produce anything like good effect the back row needs to be raised and the front row hidden with Ferns. If there were room the breaking up of the various pipe classes by dwarf foliage plants or Ferns would be a great improvement. That the method of exhibiting the flowers is not worse than that of staging blooms in 12-inch to 14-inch ware vases that have no draping foliage about them is certain, and it is difficult to understand the want of taste shown when naked ware or even glass vases are permitted to be much more in evidence than the flowers. Two years ago it was agreed to dispense with the ordinary open class for twelve Japanese blooms on boards and substitute one for twelve blooms on long stems, shown in two vases, at Kingston. But circumstances compelled the supply of large, broad-mouthed metal vases, very light, painted green, and not unhandsome, into which the whole dozen blooms were placed, with any drooping or decorative foliage added. The result was the production of some exceedingly noble objects. The class, repeated this year, has been even bettered, for the flowers were of great size, superb quality, and most effectively arranged. Some 9-inch or 12-inch vases as these thus filled and

dressed form some of the finest objects to be seen at shows. Some of the competitors said: "These flowers are to be set up at home in a large vase for the hall decoration; they are so greatly admired." That seems a good reason why huge Japanese blooms should be set up at shows in methods that are the most highly favoured in the household. When set up in baskets the flowers, having little or no water, soon decay. But fine blooms set up in vases having ample stem-room and water area last in a cool room for fully a fortnight quite fresh. It is hardly possible to provide in cut flowers any nobler or more effective objects. A. D.

BOOKS.

City Development: A Study of Parks, Gardens, and Culture Institutes.*—This fully illustrated and handsome volume has for its main purpose, as is indicated by the sub-title, "A Report to the Carnegie Dunfermline Trust," an exposition of what may be done to a large space of ground that is given by the philanthropist to his native city, and is to be laid out and built upon for the recreation and pleasant instruction of the people of Dunfermline. The plans include pleasure grounds, which embrace a wooded glen and stream of considerable natural beauty, but now defiled by outpourings of sewage and moraines of town rubbish, ancient historical remains, parkland, garden ground, sites for educational buildings of archaeological, historical, and other character, of buildings for museums of fine art, natural history, &c.; in short, of everything that may be thought of whereby a large space may be rendered attractive to persons of ordinary intelligence and wholesome tastes. Many parts of Professor Geddes's scheme appeal specially to children, the men and women of a few years hence, while the whole shows a remarkable grasp of the possibilities of the place and its new conditions, and offers an illuminating example of such like possibilities in the case of other towns.

GARDENING OF THE WEEK.

FLOWER GARDEN.

PROTECTION, &c.

THE sudden change from the soft mildness of the greater part of November to the heavy fall of snow and severe frosts experienced in nearly all parts of the country has proved disastrous to many shrubs and plants. Our climate is so fickle that, as advised in this calendar for the 5th ult., the advent of that month was a reminder to prepare for the winter. Here in North Cornwall we had 6 inches of snow on the ground, and registered 14° and 15° of frost on two different nights, besides exceeding 10° several times. This for November is more severe than has been experienced for many years. At the time of writing it is too soon to form an estimate of the damage done; but even with the customary winter protection many usually hardy shrubs and plants have suffered. As many eminent weather forecasters predict frequent short spells of weather of even greater severity than that we have just passed through, it will perhaps be wise to increase the amount of covering given to many out-of-door subjects, and, much as I am averse to coddling, I would recommend that where possible any valued examples should be lifted, potted, and wintered in frames or a cool house.

NURSERY PLANTS.

During mild spells all home-raised trees and shrubs which are not large enough for planting in permanent positions should be transplanted. It is the neglect of this very necessary operation that often causes newly-planted shrubs to remain at a standstill for the first year after planting. The

ground should be well worked, and as the aim of the cultivator is to produce sturdy growth and plenty of fibrous roots, the dressing given should be of a character to produce this result rather than to induce vigorous growth. All bruised and straggling roots should be removed with a clean upward cut, and the shoots should receive any needful regulating. The larger shrubs which will be used next autumn should be given ample room for development, and with the smaller one year old plants care should be taken to allow plenty of room for the free use of the hoe between the rows. Planting should, of course, be firmly done and the important mulching given. A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

TREE CARNATIONS.

EARLY propagation of these generally is recommended, January and the early part of February being considered the best time. Cuttings at the present time are inserted with a view to their being rooted and ready for potting off singly early in the New Year. It is from these plants that flowers of good quality and in abundance can be gathered in the autumn of the following year. January-propagated plants form a good succession to the above. For propagating in quantity obtain shallow boxes, and after draining them well place over the crocks a layer of rough leaf-soil, and finally a layer of sand 1½ inches to 2 inches in depth. Use a fine rosed can with which to water the sand, and after allowing it to drain simply stick the cuttings into the sand and place them in a close temperature of 65° to 70°. Never allow the sand to get dry, keeping the surroundings of the cuttings moist, and they will readily emit roots.

SOLOMON'S SEAL.

When forced early into growth and flower this is most useful when cut. Retarded roots force very well. They can be lifted from the ground, placed in pots or boxes, or they may be laid in the forcing-bed among Coconut fibre. The plant will thrive well in a heat of 70° to 75° with plenty of moisture, but good drainage is essential. Stagnant water about the roots is detrimental.

DICENTRA SPECTABILIS.

This is another very useful plant for forcing early into flower, and its graceful character makes it an excellent decorative plant. Although portions for potting up to force may be split off the permanent roots, they will force the best when obtained from plants that have been well grown. Do not place the roots in a strong heat at the commencement, growth is freer when they are plunged in a gentle bottom-heat, with a low top-heat.

SPIRÆAS FLORIBUNDA, JAPONICA, AND ASTILBOIDES for forcing require similar treatment, the best results, however, being obtained always from annually imported plants. They grow best with abundance of moisture and little soil about their roots.

SPANISH IRIS.

With care these can be had in flower a little earlier than is possible in the open border. It is a mistake to put them in a close, warm temperature at first, which encourages leaf growth only. Remove them from the cold frame to a shelf near the glass, and in this position leave them until their flower-spikes begin to show, after which they may be given more warmth.

J. P. LEADBETTER.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

EARLIEST PEACHES.

EARLY varieties of Peaches and Nectarines which are forced in pots, such as Hale's Early and Waterloo Peaches, Cardinal and Early Rivers' Nectarines, should be started at once if ripe fruit is to be had by the end of April or beginning of May. When these trees have been forced in previous years the buds start quickly without much artificial heat. A night temperature of 45° to 50°, 55° by day, and a further rise to 60° with sun-heat in bright weather will be

quite high enough until the trees come into flower, when a little more warmth may be given. Give a little top ventilation when the weather is favourable, carefully attend to watering and keep the house moderately moist, always allowing the buds to become dry before evening. Lightly fumigate the house once or twice when quite dry, before the trees come into flower, to ensure their being free from fly when the flowers are "setting."

SUCCESSION PEACHES.

Houses which contain standard varieties of Peaches, such as Royal George and Stirling Castle, Lord Napier and Elruge Nectarines, should be started at the same time as the pot trees, to supply fruits for the end of May and beginning of June. These varieties may always be relied upon when forced with care, and cannot be beaten for quality. Nothing is gained by trying to hasten the trees; success depends on a low night temperature, with plenty of top ventilation on favourable occasions until after the fruit is set. Carefully examine the borders for water, and do not trust to external appearances. If fermenting material is used less syringing is necessary. Turn a portion of the fermenting material at intervals, according to the state of the weather, and lightly damp it with chilled water. As soon as the blooms expand, see that they are quite dry in the middle of the day, when they should be carefully fertilised with a camel hair brush.

LATE PEACH HOUSES.

The pruning and clearing of later houses should be pushed forward and brought to a close as soon as possible. The house should then be freely ventilated, or, better still, the roof lights removed if possible. This not only retards the buds, but assists the trees to retain them, and reduces many insects, brown scale particularly. Tie in the trees, leaving the shoots 5 inches or 6 inches apart, top-dress the borders with fairly strong loam, wood ashes, and lime rubble, with a good sprinkling of bonemeal to old trees. Root-pruning and replanting should now be finished. If the roots have been disturbed or trees replanted in outside borders, the borders should be well covered with Bracken or litter. F. JORDAN.

Impney Gardens, Droitwich.

KITCHEN GARDEN.

THE change in the weather has come suddenly. Many things in the garden have now to be taken up or protected with all speed. See that Potato and other pits in the open are given an extra covering of soil or straw. Celery will also need protection. Place lights on all Endive plants still out of doors and on Parsley. Inspect the covering round Globe Artichokes, making everything secure in case the frost is protracted. Turnips may now be got out of the ground when this can be done. Give coverings to Asparagus beds, especially in cold, wet gardens. Frames containing Lettuce, Cauliflower, &c., may be kept shut except for a short time in the middle of the day, and mats put on before dark. When it is the custom to store ice this work is generally done by the gardeners. The ice-house should be cleaned out ready for filling, also a large heap should be made in a shady spot. See that all appliances are ready for the work—mallets, rafts, hooks, &c.—also supplies of clean straw and saw-dust to be in readiness. Little can be done out of doors while this weather continues, but a thorough inspection of all roots in store should be made; Pea, Bean, and other sticks got in order; sheds cleaned, &c. All vacant plots should have the requisite amount of manure placed on them now. There will then be no delay when the weather is suitable for digging operations.

FORCING.

Further supplies of Seakale and Rhubarb should now be got in. Every succeeding batch will force better. Supplies may now be placed in a bed in the Mushroom house. See that a plentiful supply of roots are lifted before the ground becomes frost-bound. Continue sowing Mustard and Cress weekly. Where hot-beds are in use extra material must be placed round them. A sowing of Beans may be made now if a good light position near to the glass

* "City Development: A Study of Parks, Gardens, and Culture Institutes." By Patrick Geddes. Geddes and Co., Edinburgh and London, 1904.

can be given to them, as the days will be longer before these are in bloom. Those sown in January, however, will do much better. A smaller pot (6 inches in diameter) should be used at this date. Continue to collect and prepare manure for making new beds for Mushrooms if these are in demand throughout the winter months. To ensure a constant supply a bed should be made every month. See that beds in bearing are damped down regularly with water warmed to a temperature of 80°.

FORCING POTATOES.

As soon as the present year is out the forcing of all kinds of early vegetables must begin. Potatoes, Peas, &c., are in good time if put in early in January; little is gained by sowing them now. Potatoes, however, should be started in shallow boxes at this date to have them well sprouted before placing them in pots. There are many varieties recommended for the purpose. Sharpe's Victor is very reliable, perhaps not an extra large cropper, but the quality is good. Sir John Llewelyn is a variety of quite recent introduction, and is a first-class Potato for this purpose. Harbinger is also a good pot sort. Choose medium-sized tubers; place them close together in the boxes in a warm house to start them. They may be damped over twice a day to promote growth. Pots may also be got ready. They should be washed clean—9-inch or 10-inch pots are best, though I have seen good crops in 8-inch. A vinery newly started will be the best place for this crop when potted.

WINTER CUCUMBERS.

To keep the plants vigorous at this season they must not be allowed to bear too many fruits. The safest plan is just to allow as many fruits to swell as are needed and no more. See that the house is damped over, both paths and borders. Frequent

light top-dressings must be applied. The outside of the house should be kept clean. Endeavour to keep the trellis furnished with young growths. Remove decaying foliage and the male blossoms. Where winter Cucumbers are not wanted a sowing should be made for early spring supplies. Sow a few seeds in a 4-inch pot and place them in the propagating frame, where they will soon germinate.

GENERAL REMARKS.

The storm reminds us that it is now time coverings were placed on all tender plants. Rhubarb should receive a good covering. It pays to place manure about the crowns, as the rains wash the substance down to the roots. Place hand frames on Cauliflower plants in the seed bed or shelter them with Spruce branches. Continue to prepare manure, and wheel it on the ground as weather permits. Garden paths should be re-gravelled and drains inspected. On wet days look over root crops that are stored in sheds, cellars, &c.

Hopton House Gardens, South Queensferry, N.B. THOMAS HAY.

CHRYSANTHEMUMS.

THE season of 1904, so far as large blooms are concerned, is now a thing of the past, and, generally speaking, it must be regarded as one of the best on record. It has been my privilege to judge at many exhibitions, and enthusiasm appears to be as keen as ever. The large numbers of new Japanese varieties introduced each year does much to stimulate the love for these, as also do the improved methods of staging and arranging the blooms. My last appointment was Edinburgh, and this show unquestionably ranks as one of the very best. I have never before seen finer Japanese flowers exhibited than on this occasion. They were massive, richly coloured, and fresh. Specimen

plants were largely shown, but I must confess these were not up to that high standard one used to see in years past at many of our leading shows.

The incurved varieties, though not shown so largely as formerly, have in many instances been unusually fine this year, and Mr. Higgs still maintains his reputation as one of the best, if not quite the best, of present day growers. Though the present affords the exhibitor some little relaxation, there is no time to spare, as preparation must be commenced shortly. A good start has much to do with ultimate results, and the old plant "stools" will need careful attention to induce them to produce stout, strong, short-jointed cuttings. The old growths should be cut down and the "stools" placed in a cool, light house, to be thoroughly fumigated, and every encouragement afforded them to grow freely. Any choice or scarce varieties which are slow to break up should be placed in a gentle heat and be freely syringed. After they have commenced to break remove them to a cooler house. New and promising varieties which have been noted, and it is

intended to get, should be ordered in good time, with a request that they be forwarded as early as possible. Cuttings should be obtained.

DECORATIVE VARIETIES.

which have been specially treated for producing a wealth of blossom for the coming festive season, will well repay any attention bestowed on them. I know of nothing more serviceable for producing an effective display in midwinter than pot plants, and for supplying a wealth of cut flowers, which are generally in great demand. The single varieties generally find much favour, and rightly so; and this section has been greatly improved of late. The plants should be arranged thinly in cool, light houses, and thoroughly fumigated to ward off attacks of green and black aphid. Mildew must not be allowed to establish itself, frequent dustings of black sulphur well applied to the under side of the foliage will effectively prevent this from spreading. Manure water should be given every other watering, nothing being better than diluted drainings from the farmyard. E. BECKETT.

Aldnam House Gardens, Elstree.

ORCHIDS.

ORCHIDS AT THE WARREN HOUSE, STANMORE.

NOT the least of the many attractions of Warren House Gardens are the Orchids. Several houses are filled with them, and as the flowering period of each sort comes round there is much to interest and please.

At all seasons of the year there is something in the way of Orchids to be seen, and on the occasion of our last visit in early November a group of *Cattleya labiata* and *C. dowiana aurea* was worth going a long way to see. Of *C. dowiana aurea* there were about fifty plants. The flowers were large and beautifully fresh, the golden yellow sepals and petals contrasting effectively with the rich purple and violet-rose of the labellum. This plant Mr. Ellis gives rather more warmth than most of the other species, both during the growing and the resting periods. The two *Cattleyas*, together with *Odontoglossum grande*, of which there were many handsome specimens, keep the houses quite bright in late autumn. In the culture of these plants success can only be achieved by persistent attention to their requirements. The group illustrated was photographed previous to the last Temple show. They were arranged in two of the Orchid houses here, and were much admired by visitors, and particularly by Mrs. Bischoffsheim, who is enthusiastic in the culture of Orchids and many other beautiful stove and greenhouse plants. Some large plants at the back of one of the groups represents *Lelio-Cattleya purpurata* var. *Schröderi*, *L.-C. russeliana*, and *L.-C. purpurata* var. *schilleriana* at their best. Some of the pans were almost 2 feet across, containing from twenty to fifty pseudo-bulbs. Of the varieties *brysiana* and *atropurpurea* there are several fine forms, some of which are occupying pots 10 inches and 12 inches in diameter.

Large numbers of *Cattleya Mossiae* and *C. Mendelii* are also grown, and added materially to the display at the period mentioned, and some of the best forms are to be seen in the illustration. *Odontoglossum citroszum* comes into flower with the *Cattleyas*, and is shown in pans overhanging the group. Mr. Ellis has abandoned the use of leaf-mould, finding that greater success attends his efforts when using compost of the following character: Good peat fibre, sphagnum moss, and a little *Begonia* leaf-soil. He says growers are finding out that leaf-soil alone is not conducive to the successful culture of *Cattleyas* in the long run. A plant may thrive in it and make sappy growth, after which the flowering period is of shorter duration, and the pseudo-bulbs more likely to shrivel during the resting season. Watering, too, has to be more carefully carried out when leaf-mould is used, more especially where large plants are grown, and the pots cannot be lifted to determine whether water is wanted or not.

GROUP OF ORCHIDS AT THE WARREN, STANMORE.

That Mr. Ellis's system of culture is good cannot be denied, when one sees several houses, each of which is filled with specimens growing luxuriantly and flowering profusely. D. B. C.

WORK FOR THE WEEK.

CYMBIDIUMS.

THESE are often given a higher temperature than is good for them, making it difficult to keep them free from red spider and thrip, and the foliage presents a sickly yellow appearance. I know no better temperature for them than that given to Odontoglossums; but many have no room in that house, so the next coolest should be the one afforded. We grow ours in the cool intermediate house, which is allowed to fall to 55° in the early morning, and rather lower during severe weather. Nothing is more detrimental to the majority of Cymbidiums than a dry atmosphere. If they are potted in good loamy soil they will only require water when they become fairly dry during the growing season, although they are moisture-loving plants. I prefer cool and moist surroundings, and watering only when they have become well dry during the winter months. C. traceyanum, the freest and

MOST DESIRABLE FOR AUTUMN FLOWERING, is now nearly over, also C. giganteum and C. affine. The quieter they can be left the better will be the next growth. C. winniamum, the beautiful hybrid between C. giganteum × C. eburneum (?) is a great acquisition to the autumn and early winter flowering sorts, and is worth a place in all collections; it flowers very freely and is a rampant grower. The flower-buds of C. hookerianum (syn. C. grandiflorum) are well advanced, and it is essential that the plants have all the light possible. This plant is very often disappointing, for when the flower-buds are more than half developed they turn yellow and drop, which, in my opinion, is caused by placing them in too high a temperature and where direct light is in some way obstructed. C. devonianum needs much light, and being of dwarf habit it is best suited when placed on a high stand clear of the other plants and at the warmest end of the cool intermediate house. C. eburneum should also be given a like position. This is generally the most difficult to grow, and the compost should be allowed to become very dry before watering. Vigorous plants of C. lowianum may be made to produce spikes by giving them a severe drying off at this season, even allowing the pseudobulbs to shrivel a little. The flower-spikes are, in most cases, in evidence on this very popular and useful species, yet the compost should be fairly dry before water is given. C. lowianum-eburneum and the reverse cross are now showing their flower spikes, and should be given a light position and allowed to become dry previous to watering. Cymbidiums have

MUCH TO RECOMMEND THEM, even to those who do not seriously cultivate Orchids. When in flower they last a long time, either on the plant or cut for room decoration. They are of simple culture and require only an ordinary compost in which to grow; they increase freely. The two things to avoid are light soil and a warm dry house. W. P. BOUND.

Gatton Park Gardens, Reigate.

THE FRUIT GARDEN.

RASPBERRY PENWILL'S CHAMPION.

THIS Raspberry is a very strong grower and a continuous cropper, fruiting for more than two months. It was exhibited before the Royal Horticultural Society at five consecutive fortnightly meetings, thus probably creating a record for a Raspberry. It received an award of merit at Holland House show on July 12 last. It has also been certificated this year at Shrewsbury Floral Fête and at Exeter and Taunton Deane shows. The fruit is large and bright red, and retains its colour well even

when over ripe. It is of firm texture, and for flavour will compare most favourably with any other variety. It was raised and is being distributed by Mr. G. Penwill, High Street, Totnes.

National Chrysanthemum Society.

An exhibition of Chrysanthemums was held by this society at the Crystal Palace on Wednesday and Thursday last. We shall give a report next week.

Improvements in Glasgow Parks.

In common with other large cities, Glasgow has a number of unemployed for whom it is desired to find work to help them through the winter. The Parks Committee is now finding employment for between 500 and 600 men. The work to be taken in hand is the formation of a pond in the Bellahouston Park. On a former occasion, when much distress prevailed, a pond was formed in Springburn Park, which added much to the attractions of that open space.

Smithfield Cattle Show.—There were numerous exhibits of horticultural interest at the annual show of the Smithfield Club. Among them were extensive displays of roots, Potatoes, Grasses, &c., from Messrs. Sutton and Sons, Reading;

RASPBERRY PENWILL'S CHAMPION.

Webb and Sons, Wordsley; Carter and Co., High Holborn (who have been appointed agents for Messrs. A. Findlay and Co.'s famous Potatoes); Harrison and Sons, Leicester; Richard Smith and Co., Worcester; Dicksons, Chester; and W. Horne, Cliffe, Rochester. Other exhibits were from Messrs. Fidler and Sons, Reading; Garton, Warrington; S. M. Thompson, Edinburgh; Scarlett, Edinburgh; A. Blatchford, Coventry; John K. King, Reading; E. W. King, Coggeshall; A. Findlay and Co., Markinch; W. and J. Brown, Stamford; W. J. Malden, Ham, Surrey; and Ransomes, Sims, and Jefferies, Ipswich.

SOCIETIES.

CORBRIDGE CHRYSANTHEMUM SHOW.

THE seventh annual exhibition of the Corbridge and District Gardeners' Chrysanthemum Society was held in the Town Hall and Drill Hall, Corbridge, recently. Messrs. Kent and Brydon of Darlington had a good exhibit of fruit under the care of Mr. Brydon, jun., and Mr. Lamont. The attendance was the largest on record. The flower stall, which was presided over by Mrs. and Miss Dodd, Lauder Grange, proved a great success. The arrangements were carried out by the committee, and Mr. J. Stamper discharged the secretarial duties. It is anticipated that the total receipts will

amount to over £90. The judges were Messrs. S. Barron, Beaconsfield Gardens, Cullercoats; J. Shotton, Prudhoe Hall Gardens; E. Keith, Wallington Hall Gardens; and T. Bell, Linwood Gardens, Jesmond Park West. The following is a list of awards:

Cut blooms: Group of plants: Mr. J. Winder, Howden Dene Gardens, first; Mr. G. Hall, Pele Tower Gardens, second. Eighteen Japanese, six varieties: Mr. J. Winder, first; Mr. W. C. Fraser, Dilston Castle Gardens, second. Twelve Japanese, not less than six varieties: Mr. W. C. Fraser, first; Mr. J. Winder, second. Nine Japanese, not less than four varieties: Mr. W. Herdman, first; Mr. W. Anderson, Farnley Grange Gardens, second. Six Japanese, not less than two varieties: Mr. W. Herdman, first; Mr. W. C. Fraser, second. Three yellow Chrysanthemums, one variety: Mr. J. Lee, first; Mr. W. Mark, second. Three white Chrysanthemums, one variety: Mr. J. Lee, first; Mr. W. Mark, second. Three, any other colour, one variety: Mr. W. Mark, first; Mr. W. Herdman, second.

Nine incurved, not less than two varieties: Mr. J. Winder, first; Mr. W. Hay, second. Three incurved, not less than two varieties: Mr. W. Mark, first; Mr. J. Winder, second; Mr. George Hall, third. Two single Chrysanthemums, disjunct, two varieties: Mr. J. Winder, first; Mr. W. C. Fraser, second.

Collection of hardy fruit: Mr. J. Waugh, first; Mr. W. Herdman, second.

Table decorations for ladies: Miss Toward, first; Miss Webb, Beaconsfield, second. Table decorations (open): Mr. Moverley, Howden Dene, first; Mr. James Hall, second.

Mr. W. C. Fraser won the silver medal for the best three blooms in the show, viz., F. S. Vallis; Mr. J. Waugh silver medal for the best collection of vegetables; National Chrysanthemum Society's certificate of merit awarded to Mr. J. Winder for best group of plants, and National Chrysanthemum Society's medal for the best vase of incurved; and to Mr. J. Lee for the best bush plant, also silver medal for same. The society awarded a certificate of merit to Mr. Harry Lloyd, gardener to Dr. Stewart of Hexham.

KIRKPATRICK-DURHAM HORTICULTURAL SOCIETY.

THE annual meeting was held in the Oddfellows' Hall, Kirkpatrick-Durham, N.B., on the 21st ult. The report of the treasurer, Mr. J. McCargo, was of a very satisfactory character, and, on his proposal, it was agreed to place two-thirds of the amount to a reserve fund, to be used only in case of need. The appointment of office-bearers was then proceeded with. Mr. J. McCartney, the president, did not desire re-election, but ultimately consented to act until a successor was appointed. The secretary, Mr. D. C. Johnston, also desired to be relieved of his duties, but agreed to act in the meantime. Mr. J. Peacock was re-appointed vice-president, and Mr. James McCargo treasurer, and the committee were re-elected with a few exceptions.

CARDIFF GARDENERS' ASSOCIATION.

THE Cardiff gardeners paid their annual visit to the Cardiff Central Free Library on Tuesday, the 29th ult., when Mr. F. E. Treseder, F.R.H.S., occupied the chair. Mr. John Ballinger, the chief librarian, received the members in his private library, where he had already placed a large collection of books relating to horticulture on the tables, and, addressing the meeting, he said that quite recently he had succeeded in securing the "Pinetum Britannicum" (three volumes, 1884), besides many others. After the members had spent a couple of hours in looking over many of the volumes, the chairman moved that the best thanks of the meeting be accorded Mr. Ballinger for the great interest he had taken on behalf of the gardeners of the district. He had been instrumental in bringing together a valuable collection of books for the aid of all those interested in horticulture. Mr. Malpass, in seconding, urged upon the young members to grasp the opportunities afforded them at the present day. The chief librarian, thanking the members, said that he was at all times ready to consider any suggestions towards adding any new books. JOHN JULIAN.

EDINBURGH SEED TRADE ASSISTANTS' ANNUAL DINNER.

ON the evening of the 2nd inst. the tenth annual dinner of the Edinburgh Seed Trade Assistants was held in Ferguson and Forrester's, Prince's Street, Edinburgh, when Mr. P. M. Greig presided over an attendance of about 100. In the course of the evening the toast of "The Seed Trade Assistants" was proposed by Mr. David Bell, Leith, who referred in eulogistic terms to the seed trade assistants of the city and to their interest in their important business. He spoke with approval of the excursions to gardens, and suggested a series of winter lectures upon subjects connected with their profession. Mr. Bell said that Scotland was the training ground for the seed trade of the kingdom, and referred to the important position in the trade taken by Edinburgh. A suitable reply was made by Mr. J. H. Young. Mr. M. Todd, of Messrs. Todd and Co., Shandwick Place, proposed "The Seed and Nursery Trade," coupled with the name of Mr. Robert Laird, of Messrs. E. B. Laird and Sons, Limited. In the course of a capital speech he spoke of the position occupied by the city in the trade, and alluded to the high positions held by men who had received their training in Edinburgh. He referred to the work done by Mr. R. Laird in connexion with the Scottish Horticultural Association, which he had stamped as one of the most successful of its kind in the world. Mr. Laird made a suitable reply, in which he remarked that he thought the seed assistants of the present day had not the same opportunities as those of former times, who had a chance of learning other departments as well. Other toasts and a capital musical programme followed, and a most enjoyable evening was spent.

ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.

THE annual general meeting of this society was held in Aberdeen on the 26th ult. Mr. S. Pope, vice-chairman of the directors, presided over a crowded meeting. The annual

report was of a satisfactory character, although the last show was hardly equal to some of its predecessors. The financial position was considered satisfactory, although there was a deficiency on the ordinary income and expenditure of £175s. 2d. This was, however, a smaller deficiency than for some time, and, in addition to £320 of bequests at the credit of the society, there is also a sum of £72 2s. 10d. to be carried to next year's accounts. In the report mention was also made of the children's competition, which was excellent, and of the indebtedness of the society to the Town Council for the use of the Pithie Park for the show. Some discussion took place upon a motion and amendment proposing alterations in the rules regarding the management of the society. The following, moved by Mr. J. M. Simpson, was ultimately carried: "That the affairs of the society be under the management of the acting directors, consisting of the chairman, vice-chairman, secretary and treasurer, and twenty members elected irrespective of any class (seven to form a quorum). The society to consist of four divisions, namely: (1) Professional and market gardeners, (2) nurserymen and florists, (3) amateurs, and (4) working class." Six gentlemen were proposed for the office of secretary and treasurer, but ultimately Mr. J. B. Rennet was re-elected by a large majority over all the candidates.

REIGATE, REDHILL, AND DISTRICT GARDENERS' ASSOCIATION.

THIS society held the fortnightly meeting on the 25th ult. Mr. W. P. Bond in the chair. Mr. Townsend of the Gardens, Sandhurst Lodge, gave a lantern lecture on "A Berkshire Water Garden in Summer." A fine collection of Nymphæas, all of which had been photographed by Mr. Townsend, were shown upon the sheet and proved of much interest to the members. Much valuable information was gained with regard to the formation of a water garden, also the position and soil most suited to this purpose. The lecturer clearly proved the value of this form of gardening. Many plants which were suitable for water gardens were mentioned, and instructions given for their culture. Some exceedingly fine specimens of *Hydrangea hortensis* and *H. paniculata* were shown upon the sheet, showing how readily these plants lend themselves to outdoor culture and what a grand display they make. A vote of thanks to the lecturer closed the meeting. F. C. L.

READING GARDENERS' ASSOCIATION.

At the last meeting of the above association Mr. C. Foster, Horticultural Instructor, Reading College Gardens, read a practical paper on "Cropping and Intercropping a Vegetable Garden." Peas were first dealt with as forming one of the chief crops of the garden, and the suggestions thrown out as to cropping and intercropping in connexion with this popular vegetable will give an idea of the comprehensiveness of the paper. Between the rows of early Peas, Spinach, Radishes, and early Milan Turnips should be taken, and with the second earlies a short-topped early Potato or early Cauliflower, such as Erfurt or Magnum Bonum, should be sown. After the early Peas are removed, Endive, Lettuce, and Spinach should be sown for autumn use. The second early Peas being cleared off at the beginning of August will allow room for winter Spinach and late Turnips. In conclusion, Mr. Foster mentioned that in cropping and intercropping a garden, the thing to aim at is the production of the largest possible amount in a given space and in a given time, and to reduce the chances of failure each successive crop should be in character as far as possible unlike its predecessor. A good discussion followed, sustained by the president (Mr. Leonard Sutton), Messrs. Powell, Wilson, Hinton, Alexander, Neve, Tunbridge, and Townsend. A splendid collection of vegetables from the college gardens was staged, and was greatly admired, consisting of Potatoes, Tomatoes, Broccoli, Carrots, Turnips, Brussels Sprouts, Endive, Chicory, &c. A hearty vote of thanks was accorded to Mr. Foster for his excellent paper, and also for sending the exhibit of vegetables.

ROYAL HORTICULTURAL SOCIETY OF PERTSHIRE.

THE annual meeting of the Royal Horticultural Society of Perthshire was held in Perth on the 26th ult. Mr. A. Coates in the chair. On account of the weather and the lack of public support at the last show the report of the secretary and treasurer was of an unsatisfactory character, there having been a loss of £87 4s. 3d. on the show. In response to a special appeal the sum of £44 19s. had been subscribed by members and other friends, and a loan of £50 had been obtained on a security held by the society. Including this sum of £50 the total receipts amounted to £253 10s. 2d. The expenditure amounted to £234 18s. 9d. The office-bearers for the ensuing year were appointed as follows: President, Mr. A. Coates of Pitculen; vice-presidents, Lord Provost Love and Mr. R. D. Pullar, Brahan; practical vice-president, Mr. E. A. Stenning, The Gardens, Brahan; secretary and treasurer, Mr. A. Brown, of Messrs. Alexander and Brown, seedsmen, Perth. The question of holding next year's show in a park at Pitculen was remitted to the committee to consider, and it was also resolved to make an effort to secure some special cups for the show, next year being the centenary of the establishment of the society.

ANSWERS TO CORRESPONDENTS.

Names of fruits.—J. H. C.—1, Alfriston, very fine; 2, Newton Wonder; 3, Alfriston; 4, Court Peudu Plat; 5, Boston Russet; 6, Tower of Glamis.

Grape for November (THORN).—The best Grape to ripen in November is Black Alicante. This is a free grower, but the quality does not compare with the Muscat.

At the same time if your house is good as regards freedom from drip and well situated you could have excellent Muscats until Christmas. Another good Grape is Alnwick Seedling, which is also late, but a bad setter in some cases, and not so reliable. The best late Grape, but a thick-skinned one, which the others are not, is Lady Downe's.

Peach for September and October (THORN). The best Peach for open wall in September and October is Bellegrarde. This with you would ripen in the middle of September. A little later variety would be Late Devonian or Sea Eagle, the last named being the latest of the two. A still later variety would be Walburton Admirable. We advise Bellegrarde or Sea Eagle.

Ramondias (MISS ANDERSON).—It is the more difficult, by reason of the position in which the plants are, to treat them successfully. We may, however, mention, in case it is possible of application, that any rough substance—coal ashes, sawdust, fine charcoal, &c.—is much disliked and avoided by the pests. We would, however, not cling too strongly to the one position, for the plants are quite at home on the level ground, and can be more readily treated generally in such places. We still strongly urge the value of soot, and though the bulk may be washed away, much of the bitterness remains, and after a few fruitless attempts the slugs will generally find a feeding ground elsewhere.

Manuring Potato ground (J. G.).—We are much interested to learn from you that Up-to-Date Potato, grown on dug-in pasture, the soil sandy, gave you most excellent quality as compared with the quality of the same variety grown in the garden. It does but furnish one more proof that soils, or rather their constituents, for it is the same thing, have great influence in the production of quality or otherwise in Potatoes. So many people who find Potato quality in any variety to be bad from their inferior soil rush hastily to condemn the variety; yet on diverse soil it may be of superior quality. What would be of great service to Potato growers would be an analysis of the diverse constituents in your old pasture soil and garden soil, as in such case we might then know much better than we do now exactly what are the soil constituents essential to the production of good quality in Potatoes. It is just possible that the dug-in pasture, when in a state of decay, did furnish some good elements to the Potato plants that were lacking in the garden soil; but, of course, with imperfect knowledge that is but conjecture. Certainly we have found good garden soil, which is deep but on a chalk foundation, to produce fine quality in Up-to-Date, although manured chiefly with tree leaves. As you wish to employ what are known as chemical or artificial manures for your Potato ground next year we advise that you purchase enough of basic slag to dress the ground at the rate of 6lb. per rod. This costs about 4s. per cwt. Have that well forked in at once. In March apply, at the rate of 4lb. per rod, fish guano, a capital manure costing 7s. per cwt., and have it at once deeply dug in. You could plant either with the aid of the dibber or by throwing out furrows with a spade a week or two later. If the seed tubers be well sprouted in shallow boxes first it will be early enough to plant in the middle of April.

Celery diseased (A. D.).—The Celery sent is badly diseased, and you note that you have followed the advice given in a vegetable book, but in the work referred to at page 44 we find the following excellent advice is given. It is as follows: "There should be no earthing up until the plants have made a full growth, for the earthing up pretty well stops the growth," that is, it is only a finishing process to bring the crop to perfection. The specimens sent were washed and trimmed. We wish they had been otherwise, as probably we should have been able to note what kind of soil, if heavy or light. There are no details to help us in discovering the cause of failure. We do not doubt for a moment but that good culture has been given; in fact, we think you may have been too good to the plants. Is the land well drained, and do you use much manure or feed too freely during growth? These are only small details, but one may go a long way to explain why such excellent Celery has decayed so in the centre. You say that last season, which was wet, the same difficulty occurred, but this year was more favourable, and your plants would not suffer from the rainfall, but from other causes, which we will describe. In the absence of details we can only come to this conclusion, that the plants have been moulded up too early, and the plant, being unable to develop its growth at the centre, rotted. This is a common failing, and one that occurs more often than one might suppose. When the plants have a large body of soil pressed hard round the tender growths, before the latter are fully grown they soon go wrong. Another thing which assists and often begins the decay is the use of strong manures, such as in chemicals or liquids. These when used to excess cause decay, also if the soil is very heavy it is much closer to the plant. Much depends upon how the earthing up is done. In your case we would in the future advise moulding up as late as possible. It is an easy matter to place a little soil occasionally to the plants, but not to finally finish earthing up until growth is complete. If Celery is wanted early only do what you require, but not that for use at this season or later. The longer Celery is left before earthing up the harder the growth, and less likely is it to go wrong afterwards.

Bright-coloured pillar Roses (A. R. A.).—One of the greatest charms of the modern Rose garden is in the free use of pillars and arches whereon to display the true beauty of the vigorous growing Roses that are now so abundant. Perhaps of all forms the pillar is the most useful. The list of some twenty-five Roses which you already had embraces many well known and valued varieties. Your present collection comprises mainly summer-flowering Roses, and for such time as they remain in bloom nothing can surpass them in beauty. Of these summer kinds we miss one well-known variety, viz., *Félicité Perpetue*, perhaps one of the loveliest of the white cluster Roses. What a height such Roses will attain! We have seen some grand specimens of this old Rose which have clambered to the top of some 20-foot-high Larch poles. You could not do better than add the varieties you propose, namely, *Blush Rambler*, with its lovely clusters of delicate pink blossoms, each flower

with two rows of petals, and extremely lasting. *Electra* and *The Garland* are also grand. *Pink Rover*, too, is one of the best pink varieties for autumn, and its blossoms are as fragrant as they are beautiful, each bud as handsome as a Tea-scented variety. We should not advise *Pink Roamer* unless you have an old tree you wish to cover quickly. You ask for a few other names of bright colours suitable for pillars. Good scarlet autumn-flowering Roses are *François Crousse*, *Gruss an Teplitz*, *Gloire des Rosomanes*, *Maharajah*, *Ards Pillar*, and *Birdou Job*. Other useful bright-coloured sorts that bloom in autumn are *Waltham Climber No. 1*, *M. Désir*, *Reine Olga de Wurtemberg*, and *Climbing Cramoisie Supérieure*. A very lovely deep pink pillar Rose is *Climbing Belle Siebrecht*. This grand variety should be in every garden. *Paler pinks* of merit are *Climbing Captain Christy* and its more magnificent rival, *Mme. Edmée Cocteau*, *Climbing Caroline Testout*, and *Conrad F. Meyer*. Two grand whites are *Frau Karl Druschki* and *Mme. Alfred Carrière*, the first-named of rigid growth and the last-named of most luxuriant growth, well adapted for a tall pillar or arch. Of summer flowerers *Philadelphica Rambler* bids fair to supplant the old *Crimson Rambler*. Its individual blossoms are more perfectly formed and of a more intense colour. *Rigosa* Mrs. Anthony Waterer makes an excellent moderately high pillar Rose. *Wichuraiana rubra* should be largely grown, as it is most valuable for cutting for table decoration. It produces blossoms in large clusters, and, being single and of a bright colour, they are most attractive. *Ruby Queen* is also good. The old Hybrid *Chinas Chenedole* and *Fulgens* are not yet surpassed; the former is a bold, handsome crimson flower, and the latter a neat little Rose of a very bright shade. *Helene*, *Waltham Rambler*, and *Tea Rambler* are splendid pillar Roses, and the same may be said of *Flora* and *Bennett's Seedling*.

Forcing Lilac (ANXIOUS).—Forced white Lilac has been much in demand of late years. The forcing of this in the way that the French market gardeners treat it, is not fully understood by everyone engaged in the production of flowers in winter in this country. It may be taken as a rule that if plants are hurried into bloom in a very high temperature it causes the flowers to come thin in texture. This is particularly the case when the plants are hardy, as the lower the temperature they are naturally able to bear the more they are weakened by being subjected to strong heat. To this Lilac is an exception, as the plants will stand a higher temperature than most things while being brought into flower without its having any effect on the flowers in the way named. Even when the plants are forced in the dark it has little influence on them as far as affecting their durability when exposed to a dry atmosphere. A temperature of from 80° to 90° is not too much to force Lilac in. When white varieties are used there is no need to darken the plants with the object of having the flowers white, but the darker coloured sorts will not come so pure in colour if exposed to too much light.

Japanese Iris from seed (CROMARTIE).—Although this Iris may be imported direct from Japan in many beautiful varieties, the raising of new sorts from seed may be made profitable as well as interesting. When left to their natural development they produce but little seed, and the varieties obtained from this are ordinarily no better, and usually not so good, as the original forms; but when carefully hand-fertilised nearly every flower so treated will produce its pod of seed and a large percentage of the flowers will be better and most of them as good as those of the parents. By actual counting it has been found that of seedlings from hand-fertilised flowers 40 per cent. were varieties worth preserving, while of plants from seed produced naturally but 6 per cent. were good. It is desirable to have some varieties to flower earlier in the season, and this may be accomplished by a careful selection of seed from those that first come into bloom.

Wintering Tigridias (AMATEUR).—Though the Tigridias will, in many places, pass through the winter in the open ground without any care or attention, yet in others the bulbs are liable to decay, especially if the season is wet, and where such is the case it is better to lift them in the autumn when the foliage dies down. They keep best when they are lifted, the old leaves cut off, and the bulbs laid on a shelf in a good dry shed till they are thoroughly ripened. Then store them in boxes of perfectly dry sand, and keep them where they are just secure from frost, when they pass the winter without injury. One point to especially guard against is to see that the sand does not get damp, and another is to keep a sharp look out for mice, as they are very fond of the bulbs.

Timber felling (G. S. GROVES).—The felling of hardwood trees should be done in the winter season, and be finished before the buds begin to expand in the spring, except in the case of those kinds of trees which are to be peeled. The axe is the best tool to use in the earlier stages of a plantations' growth, but after trees get to forty years old the saw should be used. When this work is done by the forester's own men he can generally have the work done to his satisfaction, but when the work is done by the piece by a timber merchant's men, this is not so easily done. Care must be taken to have the trees felled close to the ground, and is more especially necessary where the suckers are desired to grow up as underwood, or to come in for a succeeding crop. In felling trees grown from old stools, we often come across portions of the old stool embedded in the bottom of the tree, and as this is always partly decayed and of bad colour, it spoils the sale of the timber; whereas when a tree is grown from a stool cut close to the ground it may be cut off sound and good. Another important point to be attended to in felling is to do as little damage as possible to the standing trees by the fall of those being felled.

CATALOGUES RECEIVED.

Trees and Shrubs.—Messrs. Cibraans, Altrincham.

Seeds of Trees and Shrubs.—Messrs. Vilmorin, Andrieux et Cie, 4, Quai de la Mégisserie, Paris.

THE GARDEN

No. 1726.—VOL. LXVI.

DECEMBER 17, 1904.

A MEETING OF ROSE GROWERS.

THE annual meeting of the National Rose Society is always a pleasant gathering together of rosarians from all parts of the United Kingdom, and the meeting on Thursday of last week, of which a report is given on another page, was perhaps more enthusiastic than usual. The chair was taken by the president, Mr. C. E. Shea, whose wise remarks and tactful management of the various points which arose showed that the committee had made a right selection as their head for the next two years. There was an element of sadness in the proceedings. During the year the society has lost a great leader in the late Dean of Rochester, and the genial presence of the Rev. Foster-Melliar was much missed, and kindly reference was made to these losses by the president. A full afternoon's business was got through, this including alterations of the rules, consideration of the place for the provincial exhibition, the departure from the Inner Temple Gardens, and financial statement. Before the proceedings began the president presented a testimonial consisting of a cheque for £150 to Mr. Edward Mawley, the honorary secretary for twenty-six years—part of the time in co-operation with the Rev. H. D'ombrain—as a slight token of the esteem in which he is held by all who have worked with him in furthering the interests of the society. No man deserved better such a gift as this. Mr. Mawley, by his devotion to the society and his disinterested labours, has raised it to a proud position in the world of flowers.

The National Rose Society is an increasing influence for good in gardening; it is endeavouring to assist the beginner in every possible way by the publication of booklets in which clearly expressed information is given on "Planting Roses," "Pruning," and other subjects which must be understood before success in the exhibition can be assured. The migration of the society to Regent's Park will be watched with some anxiety. The reason for this departure is the dislike of members of the Inner Temple to the noise occasioned by a show in their restful Thames-side garden. We can understand their objection, and can only hope that the society will not suffer through losing so central and pleasant a position. The authorities of the Royal Botanic Society have, however, met the National Rose Society in the most kindly spirit.

They have promised the use of the beautiful gardens and the gate money for the day. A welcome so hearty and sincere as this will do much to remove the fears that are entertained of a failure through want of public support. The society is flourishing in no uncertain way. Mr. Hayward, the treasurer, had the happy duty of announcing a balance of £318 19s. 11d., of which £100 is to be placed to the reserve fund and £25 given towards the Royal Horticultural Hall in Vincent Square. No less than 379 members have joined during the present year, which brings up the strength of the society to 1,309. There was some discussion as to whether, with the increased prize-money given to the autumn show, the society would be justified in holding a provincial exhibition, but we are pleased that such a step has been taken. Unless the society continues to meet in the provinces, it loses its right to be called "national." There is always a danger when a society has its headquarters in London of localising the work. No greater mistake can be made. A society which calls itself "national" and cramps its energies in a London hall ceases to be regarded by its members in the provinces as a strong and progressive institution. A representative of the Gloucester Society gave the National Rose Society a warm invitation to that city, and this was accepted. A dinner in the evening closed the day's proceedings. Mr. Shea presided, and Mr. Mawley was heartily congratulated on the honour conferred upon him by the council of the Royal Horticultural Society in asking him to accept the Victoria Medal of Honour.

"THE GARDEN."

NUMEROUS letters have reached us from subscribers with reference to the reduction in price of THE GARDEN, and all write in appreciative terms of the proposed change. We should like again to emphasise the fact that THE GARDEN will relinquish none of those subjects which have always been characteristic of its pages. Its good influence in the world of gardening has never been questioned, and those features which have been contributory to this will be maintained and brought even to greater excellence. As examples of the letters we have received we may quote from the following. From Dyke, Bourne, in Lincolnshire, Messrs. Gilbert and Son write: "As a subscriber to THE GARDEN for many years we are glad to see that its price is to be reduced

on January 7 from 3d. to 1d. Above all, it is most gratifying to know that none of its traditions will be sacrificed, but that it will maintain its high standard of usefulness; in fact, we shall look forward with increasing pleasure to those GARDEN features in the new series which have been familiar for so many years. We feel sure its influence for good will widen as time goes by." Amongst private subscribers, Mrs. Davidson writes from Totnes: "I must send you a line to say how heartily I greet the new departure. I was glad, as I am sure were many others, to notice the assurance that the high standard of THE GARDEN will be maintained."

DEVELOPMENT OF THE CHRYSANTHEMUM.

MAGNIFICENT in form and varied in tints as are so many of our more highly developed flowers, it would be difficult to find any fair parallel to the case of the Chrysanthemum. A year or two ago some specimens of the original wild plant were exhibited as grown in Kew Gardens, and these, when contrasted with the finest varieties, gave a very vivid idea of the wonderful capacity for development which may exist in a flower of little promise. The normal flowers were not an inch in diameter, and little better than single Daisies, and it seemed inconceivable that the huge blooms near by, perhaps a foot in diameter, and with heaped-up gorgeously coloured petals to half that depth, could have been evolved from such a commencement.

The wonder is the greater since there is little or no evidence that these results have been obtained by hybridisation, as in the case of the tuberous Begonias; whatever crossing there has been done appears to have been between varieties only, and not distinct species. How the metamorphosis first came about is not clear, as it began in the Far East, long before the flower attained any popularity in the West, such popularity only being excited by the fact that the flowers had already become very attractive and very varied in character, both as regards form and colour. No one, however, could have dreamed at the time of its introduction that the flower would become the *raison d'être* of countless societies all over the world as it has done, nor that it would eventually develop such infinite variety and attain such immense size. Every season sees further varieties brought forward, and many fine flowers fail to receive distinctive awards, despite their beauty, owing to their representing no definite advance on types already introduced. It often, indeed, becomes a difficult matter to imagine how further improvement can arise, so perfect are many examples of each type, but every now and again Nature invents some novel feature as a fresh start, and thus prevents such a standstill as took place with the old-fashioned Dahlia before the Cactus form revolutionised the cult.

Nature, however, is not always successful in meeting horticultural tastes with her novelties, as for instance with the so-called hairy forms which

once promised to be "the rage," but have now fallen into the background. Then she invented the filamentous or thread-like petal, and we had a temporary influx of spidery-looking flowers which also failed to hold their own by comparison with their more robust companions, since they possessed absolutely none of the points which judges demand in these days to constitute an attractive flower. It is, however, unwise to throw too much cold water on these attempts at novelty, for Nature has sometimes a happy knack of redeeming their merely "curio" character by some subsequent additional touch. It is an opinion in many minds that the Cactus Dahlia strain originated in Juarez, solely from a fortunately preserved seedling of a type which, had it occurred here instead of in Mexico, in a batch of the old-fashioned Dahlias, would have been weeded out as a mere rogue.

Studying the history of the Chrysanthemum and its very humble origin, the question arises, "How many other humble flowers are there in the world which are only waiting to be taken in hand to afford a similar harvest?" We have in our mind's eye as we write the Japanese Anemone, another composite, and normally of a far more promising character. Already in this we have the beautiful semi-double form Monte Rosa, which seems to our mind to suggest great possibilities, and as an autumnal flower of perfect hardiness would form an invaluable prize could it be developed only to a tithe of the extent of the Chrysanthemum.

CHAS. T. DRURY, V.M.H., F.L.S.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

TREE CARNATION THE QUEEN.

Messrs. H. and J. Elliott, Courtbushes Nurseries, Hurstpierpoint, Sussex, send flowers of this remarkable Carnation for colour, which is a strong, almost metallic, rose. It does not burst, that is the calyx remains intact, and the flower is full and very sweet scented, a true Clove fragrance. The senders write: "The flowers were taken from a small batch of plants from which we have been cutting regularly for the last eight or ten weeks. The plant grows vigorously and blooms freely; the flower well formed, the calyx sound, and the scent quite Clove-like." A variety such as this is most welcome in December.

TWO NEW CHRYSANTHEMUMS.

I am enclosing for your table two Chrysanthemum flowers, the white one a sport from Miss F. Hicks, and the yellow one a sport from General Hutton. They both seem to me desirable varieties, and I should be glad to have your opinion of them.—F. NAPIER CLAYKING, *The Tower, Doercoort, Essex.*

[As far as we can judge from the blooms sent, the white variety would make a good exhibition flower if you could get the centre to fill up better, while the yellow one does not appear to be so good an exhibition sort as its parent, General Hutton. It would probably be more useful if grown undisbudded. If it flowers freely it might then be valuable.—Ed.]

TULIPA PRÆCOX VAR. DAMMANNI.

We have received flowers of this beautiful Tulip from Eltham, Torquay, a welcome contribution to our table at a time when Tulip flowers are not in our thoughts, and the note accompanying them is

interesting: "I greatly admired this flower in France. You will notice the fine character of the foliage. The flowers were taken from a pot, and they are the smallest. It is also coming well in the open. You will agree with me that it is a prettier object in a pot at Christmas time than the old crimson and yellow Van Thol."

SINGLE CHRYSANTHEMUM DOROTHY FORTESCUE.

Mr. Page sends from the Dropmore Gardens, Maidenhead, flowers of this very distinct and beautiful single Chrysanthemum. The flowers are of great size, but without any suggestion of coarseness, and their purity of colour is conspicuous. It is a variety to cut for the house and to grow as a decorative plant. Mr. Page writes that his plants are about 4 feet high and as much in width.

PRECOCIOUS LUCCOJUM ÆSTIVUM.

Last year and also this year I have recorded in the columns of THE GARDEN the early flowering of a form of the Summer Snowflake with me. In 1902 and 1903 it blossomed in January. It has now beaten this record by over a month, for on December 10 its first flowers, two of which I send you, opened. As I remarked on page 156, Vol. LXIII., other plants which I received from Mr. Arnott some years ago are quite normal in their behaviour. These are growing by the side of the precocious batch, which are in flower and full leafage, while the foliage of Mr. Arnott's is only just piercing the ground. I have known *Leucojum æstivum* to flower at the same time as *L. vernum*, but never before in midwinter, as these extraordinary bulbs of mine have done for the past three seasons.—S. W. FITZHERBERT.

[Welcome flowers of the *Leucojum*.—Ed.]

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 3, 1905.—Royal Horticultural Society's meeting.

January 24.—Royal Horticultural Society's meeting.

Royal Horticultural Society.—The twenty-fifth show of this society held during the current year was opened to the public on Tuesday. In addition to the show of Colonial-grown fruit and of home, colonial, and foreign preserved and bottled fruits and jams, there was a very good display of English-grown fruit, Orchids, shrubs, single Chrysanthemums, and early spring flowers. At the general meeting of the society, held during the afternoon, twenty-six new Fellows were elected. Mr. W. G. Freeman, late scientific assistant to the Imperial Department of Agriculture in the West Indies, and now superintendent of the economic collections at the Imperial Institute, delivered a lecture on the fruits of the West Indies, which was fully illustrated with models and actual specimens of the fruits in question, with diagrams, and with a long series of magnificent water-colour drawings from the Imperial Institute collection, which were shown in the exhibition hall. The lecturer remarked that the exhibits in the West Indian section rendered it unnecessary for him to devote any time to proving what must be to all a self-evident fact, that the West Indies were capable of producing a great variety of fruits of a high order of excellence. The next show of this society will be held on Tuesday, January 3, 1905.

A new yellow Chrysanthemum.—The variety Golden Standard received a first-class certificate when shown by Mr. C. E. Turner, Hale, Liverpool, at the recent National Chrysanthemum Society's show. It is a sport from Bronze Tuxedo. The flowers shown were of a clear bright yellow and of moderate size, that is to say, about 4 inches to 5 inches across. It is a Japanese variety, with petals arranged somewhat flatly. It is said to be especially good as a cut bloom; it may be cut with stems $2\frac{1}{2}$ feet to $3\frac{1}{2}$ feet long, and these are strong and erect. Twenty to thirty good

blooms may be had from one plant. It is said to be robust and a good grower, and the foliage does not droop.—Y. Z.

Swanley Horticultural College.—On the 9th inst. a meeting was held at 24, Park Lane, at the invitation of Lord and Lady Brassey, in support of this college. Sir John Cockburn, who was the chief speaker, said the great demand for lady gardeners, who had been students at Swanley, showed that the college had come to stay. But Swanley suffered from lack of funds, and he was inclined to think that was a sure sign of efficiency. With its colonial branch the college was helping, not only a great national work, but was ministering to the Empire. Other speakers were Mr. C. Buckmaster, Mr. J. C. Medd, Dr. Rawson, the Hon. Mrs. Lyttelton Gell, and Mrs. Pember-Reeves.

Dundee Horticultural Association.—The monthly meeting of the Dundee Horticultural Association was held in the Technical Institute on the evening of the 6th inst. There was a good attendance of the members. The lecture for the evening was on "Our Cone-bearing Trees," with lantern illustrations, and was by Mr. J. B. Corr, 94, Nethergate, Dundee. It was of a very interesting nature, Mr. Corr pointing out the distinctions between conifers and other plants, and discussing the classification and distribution of the genera and species. In addition to the lecture being illustrated by a number of excellent lime-light views, specimens of the cones produced by a number of the conifers treated of in the address were exhibited. Mr. Corr was heartily thanked for his valuable lecture.

Notes on the Potato.—The members of the Kingston Gardeners' Society were favoured with a lecture on "The Potato," on the evening of the 9th inst., by Mr. A. Dean. Mr. E. H. Jenkins, the president, was in the chair, and there was a good attendance. The lecturer dealt with the general character of the Potato, its tenderness and susceptibility to disease; then, referring to methods of production, described the procedure in cross-fertilising varieties to obtain new ones, the securing of seed, and raising of seedlings. Next followed reference to propagation by tubers, time for selecting them for planting, proper size of tubers, storing them in winter, in boxes or on shelves, or in pits or "pies," specially referring to some recent experiments at Leeds (in which lime was used to preserve the tubers), the sprouting of the tubers in light, later planting after the soil had become warmer in spring, &c. Then the effects of change of seed—not only from north to south, but also from stiff soils to light ones—was discussed. Then the interesting subject of the propagation by sprouts was dealt with, special reference being made to Messrs. Sutton and Sons' experiments with such raised plants and the possible effect on Potato constitutions, also on the propagation of the disease from resting spores in tubers. The lecture was illustrated by useful diagrams, various sized tubers, and by some fine samples kindly sent by Mr. James Gibson, Mr. Cooper (Home Park), and others, as well as by a singularly humorous exhibit of Potatoes to represent curious oddities by Mr. J. T. Blencowe. The production of scab was the chief element of the discussion which followed. The members will meet in a social gathering on January 6, 1905, and on the 13th Mr. Jenkins will follow with a lecture on "Hardy Perennials."

Further extension of fruit-growing at Blairgowrie.—Some time ago THE GARDEN noticed several extensions of fruit-growing which were taking place in Scotland. In the Blairgowrie district further extensions of the fruit farms are again in progress. On the estate of Ardblair, the property of Captain Blair-Oliphant, about twenty-five acres on the farm of Hillbarns are to be planted with Raspberries, while on Myreside, on the same estate, there are to be some fifty acres devoted to the same fruit. In the Rattray district a further extension of the industry is being carried out. There has arisen, it appears, a considerable demand for Raspberry jam abroad, and this has assisted in creating a larger market for the fruit. The climate of the Blairgowrie district seems to suit the Raspberry well.

Patagonian Plants.—The *Journal of Botany* for November contains the first part of a detailed description of the plants collected in Patagonia by Mr. Hesketh Prichard, of which a preliminary list was given in his book "Through the Heart of Patagonia." The identification has been undertaken by Dr. Rendle, who prefaces the list of plants with a short account of the region in which the collections were made, and the typical elements which are represented. The new species belong chiefly to characteristic temperate South American genera.

Rose Pauline Labonte.—I cannot understand why in writing of so many beautiful Roses no one has ever made mention of Pauline Labonté. It is especially beautiful in autumn, and I have been able to pick lovely specimens as late as December; it is semi-double, and of a light buff colour bordering on copper, the petals opening freely and being even rolled back, but this irregularly; they are also of a waxy consistency, which renders them very rich in appearance. I would also mention that on the 29th ult. I picked a branch of Cydonia in full flower, which is not common, I think, so late in the year.—L., *Route de Blonay, Vevey, Switzerland.*

Lecture on the flora and scenery of the Alps.—At a meeting of the Scottish Natural History Society in Edinburgh, on the 1st inst., a most interesting lecture, entitled "Notes on the Flora and Scenery of the Alps" (illustrated by limelight views), was read by Mr. J. G. Goodchild, one of the vice-presidents, in the absence of the authoress, Miss Marion J. Newbigin. Among other points referred to by Miss Newbigin were the climatic conditions of an alpine district, and their effects upon plant life. Among the points noted in this connexion as affecting the flora were such things as water supply, soil, and other influences. It was pointed out that there were three main zones of alpine vegetation, which could be broadly divided into those of deciduous trees, conifers, and alpine flowers. Miss Newbigin was heartily thanked for her interesting lecture.

Pear Bellissime d'Hiver.—Those who require the best cooking Pears would do well to give this a place. It is in season from November to April, and at a time when other fruits are scarce. Some of the cooking Pears, like the dessert varieties, are not free from grittiness, but this one is quite free from that fault. It has white flesh, finely grained, very sweet, and with a rich aroma. Our trees on the Quince stock never fail to crop even in bad seasons. I prefer it to the larger cooking varieties, though this is not quite so large as the Uvedale's St. Germain, but it crops more freely and keeps quite as long. The trees make a shapely growth. Grown as a pyramid it is one of the handsomest trees in the fruit garden. I have seen good standards, but I do not advise growing these fruits as such unless as dwarf standards, as the weight of the fruits and the necessity of allowing them to hang on the trees as long as possible cause many to drop.—G. W. S.

Carnations from Guernsey.—One of the most interesting exhibits at the last meeting of the Royal Horticultural Society consisted of the Carnation blooms from Messrs. Bell and Sheldon. Most of the varieties were of American origin, and we have never seen better blooms of Mrs. T. W. Lawson, which probably was the first to prove of much value for our markets, but since the introduction of this fine variety we have had many others which have been of equal value. Several of our leading market growers now find they are the most profitable to grow. Of those shown three gained awards of merit; they were Eucharist, blush pink, large, full, fragrant flowers, on long stems. This variety has been in cultivation in this country for some time, and is one of the very best. The President, deep crimson, is another fine variety, but there are several with flowers of similar colour and form, Harry Fenn and General Maceo being among them. The President may be a little advance on the last named. Adonis, scarlet, was certainly the finest of the colour I have seen, the large full flowers being very bright and perfect in shape. Several other good American sorts were included, and Mrs. Leopold de Rothschild is rarely seen in

such fine form as the blooms shown. It is interesting to note that the American varieties were all shown under their true names. There is no doubt that some of the American varieties have been renamed by English growers. This would not signify so much if it were not for the fact that it causes so much confusion, and it is disappointing to find that when you think you are buying a genuine English novelty it turns out to be an American (which you already have) re-christened. Now that we have the best American varieties well established there is no reason why we should not be able to still further improve them by intercrossing and raising new seedlings. English raisers have certainly lost ground by discarding the fringed petalled varieties, which were the first to be grown for winter flowering, and it would seem that the Americans have greatly profited by keeping to the true type of what was first known as Tree Carnations. The scarlet variety G. H. Crane (which gained great distinction in America a few years ago) comes very close, though an improvement on one of the first scarlet winter Carnations I knew. With this class of Carnations the method of culture goes a great way, and the American system of planting out secures greater vigour of growth than we can get by keeping them in pots. If only for stock purposes English growers should plant some out every season.—A. HENSLEY.

Campanula portenschlagiana bavarica.—The old *C. portenschlagiana* has long been known as one of the most useful dwarf plants we have. Although so dwarf it is very vigorous and enduring, and quickly covers a considerable space. On light and well-drained soils it makes a good edging plant, and is so floriferous that the flowers almost hide the foliage. Large masses of it form imposing objects in the blooming season. The variety *bavarica*, which is comparatively rare, has flowers of a deeper shade of blue; in other respects it is identical with the type, and is certainly a most desirable garden flower. Like the typical form it has a way of throwing up blooms in autumn, and one may accordingly see some in November.—J. CORNHILL.

Stokesia cyanea.—There appears to be a tendency nowadays to discard the old well-known plants in favour of a variety that blooms much earlier. In the open ground, and especially in midland and northern districts, the late-flowering variety has undoubtedly little value. In a sheltered sunny situation and when favoured with a very fine autumn the flowers will expand fairly well, but generally they do not get beyond the bud stage. Years ago it was largely cultivated by the London market growers, who treated it in the same way that Chrysanthemums are managed nowadays, that is, planted out for the summer, and lifted and put under glass before hard frosts. I am not aware if the *Stokesia* is still grown for market, but it certainly does not occupy an important position in the cut flower trade. It is, however, very useful, the culture is not difficult, and blue flowers in late autumn are scarce. The plants may either be grown on in pots through the summer, treating them liberally, or they may be set out in good ground in March, lifting when the buds are set, and putting them in pots just large enough to contain the roots.—J. CORNHILL.

Cypripedium insigne at the Woodlands.—For many years now Mr. R. H. Measures has had large quantities of flowers of this grand *Cypripedium* during November and December; but this year he has eclipsed all previous displays, having no less than 2,500 blooms out at one time, covering all the range of variety of the montana, Sylhet, Chantini, and every phase and variety of the plant. Mr. Measures has been a collector from the very beginning of the boom in *C. insigne*, even before, and he has acquired plants from nearly every importation that has come to Europe for the last twenty years. He has also imported plants direct. His var. R. H. Measures is considered by good judges to be finer than the colossal Harefield Hall variety, and this Mr. Measures had long before Harefield Hall was heard of. Magnificum, Trismegistum, Non Plus Ultra, and Facile princeps are very beautiful. Mrs. Measures, Mary Measures, Striata, Amesie,

kimballiana, Dorothy, statterianum, Sanderae, sanderianum, cobbianum, Macfarlanei, and Chantini Lindenii are among the better known forms, some of which are represented by many plants of each kind, while many are unnamed. Mr. Measures does not exhibit, but he loves his plants, and it is his great pleasure to enjoy them in quiet contemplation. The two houses that contain the majority of the *Cypripedium insigne* are what is termed "planted out," that is, all the plants are planted on the side benches, and are a mass of healthy green foliage from end to end, every plant flowering in profusion, so that from the front of the stage to the back, and the full extent of the 70 feet long houses no pot or stick or anything is to be seen but a bed of healthy plants, every one of which is full of bloom. Lycopodiums, Begonias, and dwarf plants are under the stages, and in every nook some little gem is seen. The interior of the whole house is like a little fairyland, as pretty as hands can make it—a great contrast to the dreariness prevailing outside. Great credit is due to the management in this establishment.—ARCTUS.

"The Amateur Gardener."—This is the title of a new monthly journal, published in Sydney, New South Wales. Its information is such that amateur gardeners are easily able to understand it. Roses are treated of at length. It seems rather strange to read in a gardening paper dated August 1 that "Rose pruning time is here!" Among the illustrations is one of Mr. Mawley, secretary of the National Rose Society, in his Berkhamstead garden.

Cotoneaster angustifolia.—This is one of the many interesting hardy shrubs collected in China by French missionaries, who sent seed of it to M. Maurice de Vilmorin, who raised and fruited it in his richly stocked garden at Les Barres. A number of profusely fruiting branches of this new *Cotoneaster* were exhibited for him at the last meeting of the Royal Horticultural Society at Vincent Square by Mr. George Paul, to whom he sent them. The colour of the fruit is a clear orange-yellow, which is quite new in *Cotoneasters*, and therefore a great acquisition. In general appearance the fruit resembles (in every respect save the colour) that of *Crataegus Lelandii*. Plants of this interesting new shrub can now be obtained at an extremely moderate price from M. Léon Chenault of Orleans.—W. E. GUMBLETON.

Testimonial to Professor Henslow. At a recent meeting of the scientific committee of the Royal Horticultural Society Dr. Masters reported on the steps already taken by Mr. Wilks and himself with the view of presenting Professor Henslow with some token of the gratitude of the committee to him for his ungrudging labours on its behalf for upwards of a quarter of a century. It was agreed that Mr. Wilks and Dr. Masters should carry out the wishes of the committee, and report to it on a future occasion. In the meantime subscriptions may be sent to either of these gentlemen.

Sweet Basil.—This most useful herb (*Ocimum basilicum*), though easily produced during the summer months, needs rather careful treatment in the winter time. For a considerable period I used to cultivate it in boxes about 3 feet long and 1 foot wide, but lost a great number of plants through their damping off in the foggy weather; I now therefore adopt a somewhat different method. The seed is sown in September or early October in boxes, and covered with glass until it germinates; the seedlings are then kept close to the glass until ready for removal. Instead of making use of boxes in which to grow them, I now prick them out thinly into 6-inch pots, and find that if kept on a shelf near the glass in a warm house they thrive very satisfactorily. The shoots need pinching occasionally, otherwise the plants become weak and flimsy. Many persons make successional sowings of Sweet Basil every month or so during the winter; I think, however, that in the neighbourhood of London especially it is preferable to raise the plants early, establish them well in pots, and divide them, say, into three batches. The first I would allow to grow away to furnish the first supply, and stop the others at the first joint. Thus

by the time the first lot had been cut over the second lot would be ready for cutting, and in a like manner the remaining plants would be available for a later period. As soon as the earliest ones were passed over they should be trimmed and pinched into shape and well looked after, in order that they may furnish another supply to follow that produced by the third batch of plants. Thus a succession would be maintained throughout the winter.—Y. Z.

Nerine Bowdeni.—Within the last few years we have had many beautiful new forms of Nerine, but most of them have been seedlings of garden origin. That under notice is, however, a direct importation from South Africa, which, under the lengthy name of *Nerine excellens major tardiflora*, was given an award of merit by the Royal Horticultural Society on October 18 last, since which time it has been finely in flower at Kew, firstly under the name of *Nerine lucida*, and afterwards as *N. Bowdeni*. This change of names is to be accounted for by the fact that investigation at Kew proved it to be distinct from any recognised species, hence it was named in honour of a Mr. Bowden, who first sent the bulbs to his mother at Newton Abbot, in Devonshire. The most remarkable thing about *N. Bowdeni* is the size of the blossoms, as they are larger than those of any other species, while they are disposed in a bold umbel. The colour is pale rose, with a central line of a deeper hue.—H. P.

THE FLOWER GARDEN.

THE CALLIRHOË.

USUALLY the members of the order to which this genus belongs are remarkable for their handsome and stately appearance, as instanced in the Hollyhocks. In the present family, to which the common name of Poppy Mallow has been applied, the various species are of procumbent growth, or only attain to a height of from 1 foot to 2 feet. The number of species contained in the genus is limited to seven, two of which are annuals and the rest perennials, all natives of North America. They are all of easy culture,

flourishing in rich, sandy loam in open situations or in front of taller plants in the herbaceous border. The spreading species, such as *C. involucrata* and *C. lineariloba*, are admirably adapted for covering large spaces, a single plant often forming a green carpet 3 feet in diameter, smothered with a succession of flowers during the summer months. Although the perennial species are all quite hardy and will live through the winter in suitable situations, they are apt to suffer from damp, and where the soil is at all heavy it is safer to lift the plants when they have died down in autumn and pot them up, placing them in a cold frame for the winter. Of the seven known species six are, or have been, in cultivation in this country.

C. alcaoides.—This is one of the erect-growing species, varying from a span to a foot in height, and found on barren plains in the Southern United States. The lower leaves are triangular cordate with an incised margin, while the upper ones are pedately five to seven parted. The rose-coloured or white flowers are borne on slender pedicels, and are about 1½ inches in diameter.

C. digitata (syn. *Nuttallia digitata*).—Also of erect habit, 1 foot to 2 feet high. This plant was first found by Nuttall growing on prairies in the Southern United States. The stems are few leaved, the lower ones round cordate and the upper five to seven parted. The flowers are about 2 inches in diameter, and vary in colour from red-purple to white.

C. involucrata (syn. *Malva involucrata*).—This is a free-growing, charming prostrate perennial, with slightly hairy procumbent stems and leaves, which are three to five parted almost to their base, the segments again being toothed. The colour of the flowers varies from crimson-purple to pale red; they are 2 inches across, and are freely produced during the summer months. It is a native of the Central United States, and is usually found growing on the open plains.

C. lineariloba.—The subject of the illustration is sometimes made a variety of the above

species with which it is connected by intermediate forms. It is, however, less hairy, with much narrower divisions of the leaves and pink or lilac flowers. These often have a white centre, and as the flowers get older the margins of the petals also become lighter. The trailing stems, 3 feet to 4 feet long, radiate from a rosette of radical leaves, soon covering a considerable space, and, like *C. involucrata*, it bears a succession of handsome flowers from early summer to late autumn. A native of Texas, it was introduced in 1884.

C. Papaver (syn. *Malva Papaver*).—This species is a native of the more southern parts of the United States, extending into Florida, and is usually found growing in open woods. It is not so hardy as the others, and requires a warmer and well drained position. From 1 foot to 2 feet high, with ascending stems; the leaves are similar in character to the others, but not so large and more hairy. The flowers are red-purple in colour, about 3 inches in diameter, on long peduncles, and are produced from May to September.

C. pedata.—The only annual species belonging to the genus in cultivation, but one of the prettiest and most useful. Of erect habit, it varies in height from 1 foot to 3 feet, with cordate leaves palmately lobed on the lower part of the stem and trifid leaves at the top. The cherry-red flowers are borne in panicles and have a light centre. It may either be raised in heat and planted out when large enough or sown in the open border where it is to flower. It is a native of Texas, and is found on prairies and in thickets. The other annual species, *C. scabrinsecula*, also a Texan plant, and very similar to the above, is not in cultivation.

W. IRVING.

COLOUR ARRANGEMENT IN THE FLOWER BORDER.

Or the quantities of garden visitors who come—their number has had to be stringently limited of late—not one in twenty will believe that one loves a garden well enough to take a great deal of trouble about it. In fact, it is only this unceasing labour and care and watchfulness—the due preparation according to knowledge and local experience—the looking out for signal of distress or for the time for extra nourishment, water, shelter, or support, that produces the garden that satisfies anyone with somewhat of the better garden knowledge—a knowledge that does not make for showy parterres or for any necessarily costly complications; rather, indeed, for all that is simplest, but that grows into something that is apparent at once to the eye, and sympathetic to the mind, of the true garden lover.

Advisedly is the word “true” lover of flowers used, for it is now fashionable to like flowers, and much of it is pretence only. The test is to ascertain whether the person professing devotion to a garden works in it personally, or in any way likes it well enough to take a great deal of trouble about it. To those who know, the garden speaks of itself, for it clearly reflects individual thought and influence, and it is in these lesser gardens that, with rare and happy exceptions, the watchful care and happy invention of the beneficent individuality stamps itself upon the place.

There is nothing more interesting to one of these ardent and honest workers than to see the garden of another. Plants that had hitherto been neglected or overlooked are seen used in ways that had never been thought of, and

CALLIRHOË INVOLUCRATA.

here will be found new combinations of colour that had never been attempted, and methods of use and treatment differing in some manner to those that had been seen before.

There is nothing like the true gardening for training the eye and mind to the habit of close observation; that precious acquirement that invests every country object both within and without the garden's bounds with a living interest, and that insensibly builds up that bulk of mentally noted incident or circumstance that, taken in and garnered by that wonderful storehouse the brain, seems there to sort itself, to distribute, to arrange, to classify, to reduce into order, in such a way as to increase the knowledge of something of which there was at first only a mental glimpse, and so builds up in orderly structure a well-founded knowledge of many of those things of everyday outdoor life that add so greatly to its present enjoyment and later usefulness.

So it comes about that some of us gardeners, searching for ways of best displaying our flowers, have observed that whereas it is best, as a general rule, to mass the warm colours (reds and yellows) rather together, so it is best to treat the blues with contrasts, either of direct complimentary colour, or at any rate with some kind of yellow or with clear white. So that whereas it would be less pleasing to put scarlet flowers directly against bright blue, and whereas flowers of purple colouring can be otherwise much more suitably treated, the juxtaposition of the splendid blues of the perennial Larkspurs with the rich colour of the Orange Lily (*Lilium croceum*) is a hold and grand assortment of colour of the most satisfactory effect.

Some sort of garden knowledge is so generally professed in these days, and so much more gardening of the better kind is being attempted that people are gradually learning the advantage of planting in good groups of one thing at a time. The older way of putting one each of the same plant at regular intervals along a border—like buttons on a waistcoat—is now no longer tolerated, but a great deal has yet to be learnt. Even planting in bold groups, however good the plants, will be ineffective if not absolutely unfortunate, if relationship of colouring is not understood. The safest plan is to plant in more or less graduated harmonies as to the warm colours, such as full yellow with orange and scarlet, and to plant blues with contrasts of yellows and any white flowers. Then delightful effects may be obtained with masses of grey foliage, such as Lavender, Lavender Cotton, and Stachys, and white Pink, with flowers that have colourings of tender pink, white, lilac, and purple. To acquire a colour eye is an education in itself, founded on the needful natural aptitude, a gift that is denied to some people even if they are not actually colour-blind. But it is a precious possession where it occurs, and all the better when it has been so well trained that the eye is enabled to appreciate the utmost refinements of colour values, and when this education has been carried to the point necessary for the artist, of justly estimating the colour as it appears to be. This is the most difficult thing to learn. To see colour as it is is quite easy. Anyone not colour-blind can do this. But to see it as it appears to be needs to be learnt, for upon this acquired proficiency depends the power of the artist to interpret the colours of objects and to represent them in their right relations.—From *Elgood's "Some English Gardens."*

TREES AND SHRUBS.

COTONEASTER HORIZONTALIS.

WHEN grown in the open this forms a prostrate, spreading shrub. It is a native of the Himalayan region. To see it at its best, however, it should be planted, as shown in the illustration, at the foot of a low wall, to which the main branches should be fastened as they develop, allowing the remainder to grow at will. In the course of a

year or two it will form a plant 3 feet to 4 feet through at the base, and gradually sloping back to the wall at the upper part. The secondary branches are arranged in flattened, irregularly fan-shaped fashion, and are clothed with tiny, ovate, dark green, shining leaves, which take on a rich bronzy tint in the autumn before falling.

Though this plant is deciduous, it is usually December before the leaves are all off, and in a mild season it will keep its leaves through the greater part of the winter. The flowers open in April or May, and are small, white, and inconspicuous. They are followed by small oval or round berries, which take on a bright scarlet colour, and last on the plant until the leaves fall. Apart from its value as a wall plant, it is useful from the fact that it likes a dry, sunny spot, where it is often very difficult to establish any other climber. It is not at all particular as to soil, but it seems to thrive best in a dryish, sandy loam, the main point being to give it a sunny spot, as it is not at all partial to shade. It can be propagated by cuttings of ripened wood or by seeds, which germinate readily. In addition to being a splendid wall plant, this Cotoneaster is very useful for a sunny place in the rockery.

Bagshot, Surrey.

J. CLARK.

THE MAIDENHAIR TREE (GINKGO BILOBA).

So distinct is this tree that there is not the least danger of confounding it with any other, while it is, in addition, of much ornamental value, and remarkably interesting, as it is the sole representative of a type of vegetation long since extinct. This is so well told in Messrs. Veitch's "Manual of Coniferae" that an extract therefrom may well be excused.

"Ginkgo is monotypic. The existing species is the sole survivor of an unknown number of others widely dispersed during geological ages over what is now the temperate and colder parts of the northern hemisphere. Fossil remains of Ginkgo have been discovered in systems that were in course of formation at a remote epoch of the earth's history, and which show conclusively that the genus is of astonishing antiquity, and that the first appearance of its ancestral form antedates that of every other existing tree by æons of time. The Ginkgo thus presents to us at least one form of vegetation that flourished on the earth when it was inhabited by unwieldy Ichthyosaurs, gigantic toads, and monster Deinotheriums, ages before man entered upon his inheritance. If the association of the Ginkgo with the remote past is of a kind to excite wonder, its recent history is scarcely less a subject for surprise, for the origin of the existing species is shrouded in mystery as obscure as that of its remote ancestors. Its habitat is practically unknown. No naturalist can say that he has seen

COTONEASTER HORIZONTALIS AT KEW.

it in a wild state, and hypothesis alone suggests that it may possibly be found wild in some unexplored district in Eastern Mongolia. For centuries it has been preserved alive by the Chinese and Japanese, who, by associating it with their religious worship and planting it near their shrines and temples, have invested it with a kind of sanctity that has contributed immensely to its preservation amidst a dense population among whom the struggle for existence has long been of an acute kind, and whose resources of fuel and timber have always been extremely restricted. Thus preserved 'it stands alone a perfect stranger in the midst of recent vegetable forms.'

To come to its more recent history, this Ginkgo was introduced into Great Britain about the year 1750, and the first recorded instance of its flowering in this country was in 1795, a specimen being trained to a wall at Kew, which tree still stands, though the wall has been long since removed. A lifelike illustration of this particular individual is given in "Trees and Shrubs for English Gardens," and a fine specimen at Frogmore is also figured in the same work. In this its destructive characters of growth may be noted, viz., the tendency for the trunk to divide up into two or three branches, which all grow erect, or nearly so, the horizontal position of the branchlets, and the drooping character of the minor spray. Besides this the leaves, in shape like the pinnules of the Maidenhair, are widely removed from those of any other tree, and from their shape impart a light and airy aspect to a large specimen. In the autumn the foliage changes to a bright golden colour, when its beauty is most pronounced, but as a rule not of long duration. There are at least three well-marked varieties in cultivation, but

none of them are, however, equal to the typical form. They are macrophylla, leaves much larger than those of the type; pendula, of weeping growth; and variegata, the leaves blotched and streaked with yellow.

The Maidenhair tree is not at all particular in its cultural requirements, but it succeeds best in a good open loam that, though effectually drained, is not parched up at any time. The severest winters do not trouble it in any way. Beside the name of *Ginkgo biloba* it is often known as *Salisburia adiantifolia*, but the first name is now adopted by nearly all botanical authorities. Among its other features is that of succeeding better than most trees near large towns. H. P.

THE FERN GARDEN.

HARDY FERNS IN WINTER.

IF fully exposed during the winter many of our most beautiful hardy Ferns suffer. When under cultivation it often occurs that they do not get the protection they find in their natural habitats. The leaves from deciduous trees provide both protection in winter and suitable material for the new roots to start into in spring. Grasses and other herbage also assist in protecting the crowns during the winter. It appears to me that many who try to cultivate hardy Ferns forget that they are depriving them of the protection they find under natural conditions, and consequently do not succeed. Of course it is not necessary to allow Grass and all kinds of weeds to grow up among the Ferns, yet something should be done in the autumn to make up for this deficiency. A good mulching of leaves may be recommended; either new leaves or those half decayed may be used. I prefer the latter, as they provide more nourishment for the young roots in spring. And besides this, if the plants are much exposed, they should have a covering of dried Bracken or other light material. Bracken is about the best thing that can be used, as it will gradually decay, and by the time the Ferns start into growth the young fronds will be able to push through. Spring frosts are often destructive to hardy Ferns. Many of our British Ferns are worthy of cultivation under glass, more especially the beautiful varieties of the Lady Fern. The beauty of *Athyrium (Asplenium) Filix-femina plumosum* is not excelled, if equalled, in any of the exotic Ferns. When grown under glass care should be taken not to excite them into premature growth. Although a little heat will do no harm in the spring while they are making their growth, giving them warmth during the autumn and early part of the winter will excite them and materially weaken them. Some of the hardy Ferns may be kept in warmth during the winter without suffering much. I find that many of the hardier exotic Ferns will also suffer much if kept too warm during the autumn, though they will grow well in the stove during the spring and summer. F.

A GENERAL CALENDAR.

WINDOW FLOWERS.

PLANTS suitable for the window are not so easily found as may be supposed. Sometimes we see Snowdrops, Aconites, or Crocuses growing in windows, but these are seldom as beautiful as those grown in the open air, for the cold is not uncongenial to these plants, and the warmth of a room is far more likely to weaken them than to develop them to greater advantage. The *Coronilla (Coronilla glauca)* is a first-class window plant. It is evergreen and almost always growing. It flowers twice in the year when well managed. The same plant may be preserved for many years, and can be handed down from one generation to another. It is fairly hardy, and whoever fails to keep it for some years, and to have at least one display of its golden flowers annually, has very much to learn in the way of plant growing.

Single Chrysanthemums.—What intense interest is shown in every direction at this season of the year in exhibiting Chrysanthemums, and the bigger they are, apparently the better they are liked, whilst the single forms have to take a back seat. But those who love flowers because of their intrinsic beauty, and not because they win prizes, prefer the light graceful singles. These flower most profusely, they need little or no disbudding, they are very light and elegant for vases, and will last fully a fortnight if cut while still at their best. Single varieties would be much more largely grown if only their ideal qualities were better known.

Iris reticulata.—There is a charm about this lovely Iris that renders it unique more particularly the strong violet perfume of its flowers. Those who grow this Iris in pots should now introduce them into slight warmth, e.g., on a shelf of the greenhouse quite near the glass, flowers may then be expected the early part of January.

Michaelmas Daisies.—Few flowers are more useful than the Michaelmas Daisies. When left year after year in poor soil to struggle for life with all sorts of other plants they do not strike one as worthy of much care, but when planted out good distances apart on fresh, deeply-cultivated soil they will astonish even those who have grown them for years.

Primroses.—It is not often that these simple but beautiful hardy flowers give us such a fine early winter display as they have done this year. Each year a few should be raised from seed and planted about in any spare bit of shrubbery or herbaceous border. In moist, heavy soils they luxuriate and form large-spreading masses that one can cut handfuls of flowers from daily in the spring.

Solomon's Seal for forcing.—Of all hardy plants this is one of the easiest to force into flower. If wanted to flower quickly, a brisk bottom and top-heat is needed, otherwise the gentle heat of a bed of leaves will suffice. The pots should be plunged rather deeply in the leaves so that the crowns also are covered. After they have made from 5 inches to 6 inches of growth, gradually

inure them to the light and place them near the glass. When the flowers begin to open remove the plants to a cooler place.

Norwich.

T. B. FIELD.

THE ROSE GARDEN.

ROSE ANALYSIS—III. GARDEN OR DECORATIVE ROSES.

M^R. MAWLEY'S comments on this table are brief, and I give them in full. They are as follows:

GARDEN OR DECORATIVE ROSES.

"The term 'garden' Roses is still used, but it is a very misleading term, as many of our beautiful exhibition Roses are equally good for general cultivation. It is here meant to apply to those varieties which are either not sufficiently large, or not sufficiently regular in form to allow of the individual blooms being set up singly at shows in boxes like the Roses with which we have previously been dealing. In the following table the varieties are arranged according to the average number of times they were staged in prize-winning stands at the last five metropolitan exhibitions of the National Rose Society, and no Rose has been included, bunches of which have not been exhibited at one or other of those shows three or more times. William Allen Richardson is still the leading flower in this section, followed by Marquise de Salisbury, which takes the second place previously occupied by Gustave Regis (No. 3). Next comes Leuchstern (No. 4), which has risen three places since last year. The varieties most frequently shown this year arrange themselves in the following order: Crimson Rambler, W. A. Richardson, Marquise de Salisbury, The Garland, Leuchstern, Mme. Chédane Guinoisseau, Camoens, Gustave Regis, Mme. Pernet Ducher, Rosa macrantha, Claire Jacquier, and Perle d'Or."

GARDEN OR DECORATIVE ROSES.

(TABLE III.)

Position in Present Analysis.	Average Number of Times Shown in the Five Years 1900-1904.	No. of Times Shown in 1904.	Name.	Date of Introduction.	Colour.
1	10.6	12	William Allen Richardson, N.	1878	Deep orange-yellow
2	9.0	12	Marquise de Salisbury, H.T.	1891	Bright crimson
3	8.4	5	Gustave Regis, H.T.	1890	Nankeen yellow
4	8.0	9	Leuchstern, Cl. Poly.	1899	Bright rose
5	7.6	14	Turner's Crimson Rambler, Cl. P. & L.	1893	Bright crimson
6	7.4	9	Mme. Chédane Guinoisseau, T.	1880	Clear bright yellow
7	7.4	8	Mme. Pernet-Ducher, H.T.	1891	Canary yellow
8	7.4	8	Rosa macrantha, S.	—	Flesh
9	6.6	9	Camoens, H.T.	1881	Glowing rose
10	6.0	6	Queen Alexandra, Cl. Poly.	1901	Rosy pink
11	5.6	5	Reine Olga de Wurtemberg, H.T.	1881	Bright light crimson
12	5.4	8	Claire Jacquier, Cl. Poly.	1888	Nankeen yellow
13	4.6	3	Paul's Carmine Pillar, S.	1895	Carmine
13	4.6	5	Souvenir de Catherine Guillot, T.	1896	Coppery carmine
13	4.6	11	The Garland, H.C.	—	Blush
16	4.5	5	Mme. Jules Grolez, H.T.	1897	Clear rose
17	4.4	5	Mme. Falcot, T.	1858	Deep apricot
17	4.4	4	Rosa Mundi, Damask	—	Red, striped white
19	4.3	1	Purity, H.E.	1898	White
20	4.0	4	Lady Curzon, Damask	1901	Pink
20	4.0	6	Mme. Abel Chatenay, H.T.	1895	Salmon-pink
20	4.0	4	Mme. Ravary, H.T.	1899	Orange-yellow
20	4.0	4	Papillon, T.	1882	Pink and white
20	4.0	4	Una, S.	1900	Pale buff
20	4.0	4	The Wallflower	1900	Rosy lake
26	3.8	3	Anne of Geierstein, Sweet Briar	1894	Dark crimson
26	3.8	4	Bardou Job, H.T.	1887	Glowing crimson
26	3.8	4	Ma Capucine, T.	1871	Bronzy yellow
29	3.7	6	Cecile Brunner, Poly.	1880	Blush
30	3.6	6	Paul's Single White, S.	1883	White
30	3.6	7	Perle d'Or, Poly.	1896	Nankeen yellow
32	3.5	3	Hélène, Cl. Poly.	1899	Pale mauve
32	3.5	4	Liberty, H.T.	1900	Velvety crimson
34	3.4	4	Hebe's Lip, Sweet Briar	—	White, picotee edge
34	3.4	3	Red Damask, Damask	—	Red
36	3.3	2	Leonie Lamesch, Poly.	1899	Bright coppery red
37	3.2	5	L'Idéal, N.	1887	Metallic red
37	3.2	5	Rosa moschata alba, S.	—	White
39	3.0	3	Alister Stella Gray, N.	1894	Yellow
39	3.0	3	Crimson Damask, Damask	1901	Bright crimson
39	3.0	3	Jersey Beauty, H. Wich.	1890	Pale yellow
39	3.0	3	Rubin, Cl. Poly.	1900	Crimson

* These are new varieties, which according to their ages have been either given an average for two years, or are placed according to the number of times they were staged at the last exhibition alone.

I quite agree with Mr. Mawley's comments on this table. It is not what it represents itself to be, namely, a table of the most useful garden or decorative Roses—far from it. But the fault lies with the National Rose Society. It is really only a table of these Roses that the schedule of the National Rose Society permits to be shown in those classes, which I presume, for the want of a better name, it calls garden or decorative Roses, and it is therefore only likely to be of service to those nurserymen and amateurs who exhibit, or wish to exhibit, in those particular classes in the schedule, namely, for Roses "shown in bunches." Therefore only such Roses as "bunch" well will be found therein. This question of garden or decorative Rose is one of those that the National Rose Society will have seriously to consider. Either the name of the section in the schedule must be altered or such Roses as Caroline Testout, Viscountess Folkestone, La France, &c., must be included, because there is little doubt that the true garden or decorative Rose is to be found in the Hybrid Tea class if it is to be found anywhere, and to exclude from exhibition in a garden or decorative section the many Roses that are the best for the purpose does not strike one as being either wise or expedient. The table includes many of those Roses that are not garden Roses in the true sense of the word. I mean all the early or only once-flowering varieties, and they, surely, are not true decorative plants. Their flowers, especially the single-flowering varieties, are perhaps the most beautiful of any. I am not finding fault with the flowers, only with the system that says these and these only are the garden or decorative Roses. The National Rose Society will no doubt alter this anomaly, for anomaly assuredly it is.

The National Rose Society held, for the first time in its history, this year an autumn Rose show, and, taking into consideration all the circumstances, it undoubtedly was a great success, for it was necessarily an experiment. It was held on September 20, and there is no doubt that to many who do not grow Roses it was a revelation of their perpetual-flowering character. Mr. Mawley did not let the opportunity slip, and the three tables below give the result:

A comparison with the summer show figures should not be without interest. We find that the three leading Teas are identical, although the Cochets change places and head the list of the most frequently exhibited varieties. Then comes Mrs. John Laing at the head again of the Hybrid Perpetuals, closely followed by Caroline Testout and Bessie Brown, so that Caroline Testout comes in the first six instead of Mildred Grant, which, after all, is perhaps what one would have expected.

Mr. Mawley concludes his most interesting article as follows: "There are many beautiful summer-flowering Roses now in cultivation, but in my opinion, and speaking generally, one continuous flowering variety is worth a dozen which bloom only once in the season. I do not think it is sufficiently realised what continuous flowering plants many of our Roses with due care and attention can be made to be. In fact, considering the long period they continue in bloom, they may be regarded as the freest blooming of all hardy plants. For instance, a garden in which continuous flowering Roses were alone grown would remain more consistently gay from the middle of June until the middle of November than if planted with any other flower. In addition to the varieties named in the tables of Roses most frequently exhibited at the recent autumn Rose show may be mentioned, among others, Antoine Rivoire (H.T.), Augustine Guinoisseau (H.T.), Camoens (H.T.), the common China (C.), Dr. Grill (H.T.), Fabvier (C.), Killarney (H.T.), Lady Battersea (H.T.), Mme. Abel Chatenay (H.T.), Mme. Eugène Resal (C.), Mme. Pernet-Ducher (H.T.), Mme. Ravary (H.T.), and Viscountess Folkestone (H.T.). Formerly, our freest flowering Roses were the Teas, but now, as will be seen by the above list, which could readily be extended, it is the Hybrid Teas which are the truest perpetuals."

I cannot do better than conclude my comments, as I commenced them, by thanking Mr. Mawley on behalf of all Rose exhibitors for the trouble he has taken for so many years over this matter of exhibition Rose analysis. HERBERT E. MOLYNEUX.

DAFFODILS IN AN ANTRIM GARDEN.

LET us not be depressed by the dull and dreary days of winter which are now upon us; rather let us look forward hopefully to the delights of the spring that is surely following upon their heels. In a few months the Daffodils will be with us again. Daffodils! there is magic in the word. What memories it now awakes in my mind of incidents in their pageant of glory last spring. Prominent among these visions of last season's Daffodils is the remembrance of one calm soft April day when I saw a collection in full bloom, revelling in ideal soil and conditions in the loveliest old garden in the county. First let me describe the situation of this little Eden. It lies in the midst of the most beautiful scenery in the county of Antrim, it nestles in a hollow on the hillside sloping to the south, and is sheltered from every wind that blows. In it the Myrtle reaches a great stature, and Azaleas attain the proportions of small Rhododendrons, and in due season blaze with gorgeous colour, while great Hydrangeas are

smothered in blossom. You may stand at the upper end of it and look out over the tops of trees below to the broad beautiful bay, beyond which rises one of the most magnificent headlands of the famous Antrim coast. On the day I went to see the Daffodils the wonderful peacefulness of the spot delighted me; the air was still, and there was silence, only broken by the song of the birds in the trees; the bay stretched out below, placid and silver-grey.

And what of the Daffodils? There they were, in groups and clumps all over the upper part of the garden. Let us now wander through this little paradise of Daffodils. Here is the beautiful bicolor Mrs. Walter Ware, with its rich gold finely frilled trumpet, beside it is a clump of bicolor J. B. M. Camm, pale and delicate by comparison, with milk-white perianth and exquisite trumpet of a peculiar shade of lovely butter or creamy yellow; it is a flower of fine substance, borne on a stiff stem, is a vigorous grower, and one of the most delicately beautiful; also being now very moderate in price, it should be in all collections. Then there were many clumps of the white trumpet Mrs. Camm; it was growing with great vigour, and the blooms were unusually large and very beautiful with their distinct drooping habit, characteristic of so many of the white trumpets. Yellow trumpets were not wanting. There were quantities of the grand M. J. Berkeley, with their magnificent expanded serrated trumpets, often attaining a width of 2½ inches at the mouth; groups of giant blooms of Glory of Leiden stand erect and look you in the face. Never have I seen this Daffodil so fine, the individual blooms were grand to look at, measuring 4½ inches across. Mme. Plomp was close by carrying blooms of amazing proportions on stems as thick as walking sticks. Empress was also producing huge blossoms and magnificent foliage. Empress is now well known, deservedly popular, and very plentiful. Although an older variety than Mme. Plomp, it is to my mind decidedly better, being a much more refined flower; indeed, I do not know a more lovely Daffodil than a well-grown perfect bloom of Empress, with its magnificent flat white perianth spread out at right angles to the splendid golden trumpet, and no variety produces finer foliage. Mme. Plomp is a larger flower, but not so well formed, and a little coarse. Gloria Mundi was there too, a superb flower, with brilliant clear golden yellow perianth and large expanded cup of rich coppery orange-red—a grand bloom that grows with great vigour. I have it in my own collection, and consider it one of the very finest extant. I discovered that its perfume slightly resembles that of Nutmeg. This may be laughed at, but it was acknowledged by all whose attention I called to it. The Leeds were not forgotten; there was a colony of them by themselves. Duchess of Westminster like a great white star, and Beatrice, pure as snow except for the merest suggestion of pink in the cup, were among them. Barri conspicuous grew in a great mass, and bore a profusion of flowers as big as an ordinary Sir Watkin. I have never seen such splendid blooms of this popular variety. Noticeable here and there were the remarkable deep orange-toned flowers of Santa Maria, a Daffodil that will not grow everywhere, and of course other standard sorts like Emperor and Sir Watkin were represented; but one remarked the absence of the magnificent Maximus, and I am told, strange as it may seem, that it absolutely refuses to grow here, where Daffodils luxuriate, even though it has been tried in every possible way. It is most capricious, and I have never been able to get any very definite information with regard to its culture. I have it myself, but it is not at all vigorous with me. At another part of the garden my attention was attracted by the graceful Incomparabilis Beauty and C. J. Backhouse, with fiery orange-scarlet crowns. A fine effect is obtained on a shady bank beneath tall trees outside the garden, where the charming sky-blue Anemone apennina carpets the ground, with here and there a dainty blossom of the dear little white Daffodil Irish Cernuus rising above the tender green foliage. This little Daffodil is always happiest when seeking its livelihood in a poor soil full of the rootlets of other plants or in the grass.

G. L. WILSON.

ROUND ABOUT A GARDEN.

WHERE THE OLD HEDGE STOOD.

LOOKING at the groups of trees to-day in the pasture beyond the fence, I was struck by the way in which the Walnuts from a single old tree in a garden may be disseminated by the rooks over the surrounding fields; for there is no clump of large trees within sight which has not at least one lusty Walnut in its midst, sprung evidently from some Nut which a rook had carried off and dropped by accident from the branch on which he had alighted to extract the kernel. And the clumps of trees tell more of the history of timber growth than this; for on looking at them carefully you can see that they stand almost in straight lines, parallel to the present hedges. This accounts for the fact that two of them have extremely ancient Hawthorns in their midst, clinging to existence although they have been hopelessly

Walnut tree began to bear a crop to attract the rooks; and since then the growth of the clumps has been further extended by a few Elders and a number of young Hawthorns, which are tangled with Brambles, on the outskirts of each group of trees. Thus, if the place were fenced from cattle the next generation would see patches of varied woodland appearing, all sprung from seeds brought to the clumps by birds.

WASTED SEEDS.

You have only to take a little notice of the doings of the birds in the garden to see what industrious agents they are in forestry, and to understand why Ivy, Brambles, Oaks, Hawthorns, and Elders are perpetually springing up where they are not wanted in the shrubberies. In the case of most garden trees, however, the labour of the birds is wasted. Although, for instance, there may be scarcely a square foot in one part of the garden which the missel-thrushes are not now littering with seeds of the Yew, as they have done in every previous

to grow vigorously in the shade when young, and to get the better of its neighbours afterwards in the free fight for elbow-room. The Hawthorn manages this by sending up strong stiff shoots which cannot be pushed aside, and then, when it has reached daylight, by producing thorny twigs which branch and interlace at every angle, so as to monopolise the invaded space entirely. The Elder's method is different, for it depends entirely upon the rapid growth of its straight shoots each season, so that its canopy of broad leaves may overtop its neighbours and shut them out from the daylight. In any hedge where the Elder has gained a foothold you may see the success of this manoeuvre, even against the fighting Hawthorn; for each year the gap in the hedge where the worthless Elder stands grows wider, the Hawthorns on each side dying away as they fail to reach the sunlight. The Ivy's method, of crawling along the ground till it reaches a neighbour's trunk and then crawling up that to daylight, is simple, but effective; while the Bramble, with its far-flung loops of new shoots, which take root from their tips and so enable the plant to smother from the outside the neighbours in whose shade its infancy was protected, seems the best of all.

BIRDS OR TREES.

It is no wonder that these plants, thus equipped for fighting and scattered broadcast annually by the birds, should prove almost as ineradicable from a shrubbery as weeds from a sown field. Nor, when we see how each old stump and wall on which the birds alight is sprinkled with seeds, is it difficult to understand how Hawthorn and Bramble, Elder and Ivy so frequently find foothold in almost inaccessible crevices of cliffs and ruins. And an interesting problem suggested by the agency of birds in spreading the trees whose seeds they eat, is the question whether in certain neighbourhoods we owe the presence of particular birds to the fact that their favourite fruit trees grow there in abundance, or whether the abundance of the trees is owing to the regular presence of the birds. Do the multitudes of redwings and fieldfares which come over every autumn stay with us because the land is so full of berries for them to eat, or is the land full of berries because in previous years they have scattered the seeds of berry-bearing trees far and wide? Indeed, for all that we know to the contrary we may owe the existence in Britain of most of our berryed trees to the agency of birds which brought the seeds over in their crops in the first instance.

E. K. R.

SINGLE PLANT OF EUCHARIS AMAZONICA AT KNOTTY ASH.

overshadowed for many years by giant Elm or Ash, as well as younger Oaks, Willows, and Walnuts. In one case the old Hawthorn is so gnarled and twisted up with the trunk of the Elm that it looks like a fantastic Japanese wrestler trying to throw a gigantic antagonist. Evidently these clumps of trees mark where old hedges stood, and the two veteran Hawthorns are all that is left of the hedge itself, having been sheltered and protected somewhat from the cattle by the hedgerow Ash or Elm which grew by the side of each.

THE GROWTH OF WOODLAND.

The next chapter in the story of the clumps evidently began with the dropping of Acorns by rooks which had brought them to the trees to eat; but the agency which brought the Willows is not quite so clear, though their seeds are woolly and adhesive and easily transported by birds. The planting of the Walnuts evidently dates, however from the time that the garden

winter, it is rarely indeed that a Yew seedling appears anywhere. These are not fitted to hold their own against the rank and rapid growth of herbage in rich soils. The Holly, too, is so slow of growth that it cannot survive the jostling of herbaceous plants for elbow-room, and only multiplies freely in shady places where few other things can grow, and where even its own ultimate hope of success in life depends upon the death of the trees which gave it shelter in its infancy. In a wood, therefore, where clumps of Holly grow in natural vigour, you may be sure that they mark the place where formerly some shady monarch of the forest, probably a Beech tree, grew.

PLANT WARRIORS.

Bramble, Hawthorn, Elder, and Ivy are the four plants which each in their season most effectively tempt the birds to sow their seeds and make most profit by the transaction. The reason is that each of these plants is specially qualified

A NORTH COUNTRY GARDEN.

THE accompanying illustration shows the grass walk down the centre of the kitchen garden, with herbaceous borders on each side. The grass is much pleasanter to the eye and to walk on than gravel, especially during the summer months. The border is chiefly planted for summer effect with single Hollyhocks. These are mostly self-sown, and are allowed to grow wherever they come up, if not too near other plants. Sometimes they reach 12 feet high. After two years these are of little or no use. There are large clumps of *Anemone japonica alba*, *Chrysanthemum maximum*, *Helianthus*, Japanese *Pæonia*, *Rudbeckias*, *Phloxes* in variety, *Delphiniums*, *Galega officinalis*, *Funkia grandiflora*, *Lad's Love*, with clumps of *Nicotiana glauca* and *Stocks* for scent in the evening. An old Apple tree stump covered with *Clematis montana* looks very pretty when this is in flower; it also relieves the outline of

the border a little. Many other plants, including annuals, fill in the bare spaces between the herbaceous plants. In the background are Scarlet Runners trained on strings about 7 feet high. These are tied to wire running the length of the borders. They form an admirable screen for vegetable crops.

Most gardeners that I have met are afraid to disturb Eucharis bulbs, especially when they are attacked by the mite, lest they should lose them altogether. I think that is where they make a mistake. None have been in a worse condition than those shown in the illustration were a few years ago. The end of February or beginning of March, I think, is the best time to repot them. Most or all of the bulbs will have flowered by that time and have commenced to make new growth. This year the four plants were turned out of their pots about the time mentioned above, all soil removed, taking as much care of the roots as possible, the bulbs washed, any unhealthy portions cut out, and scrubbed with a brush. Fill the new pots with crocks, and place sticks around the sides with some string tied to them to hold up the leaves, having previously prepared some good loam, mixed with sand and charcoal. Place the bulbs close together, covering them a little below the neck and as deeply as they were in the old pots. Make each bulb firm as the work goes on. Very little soil is necessary below the bulbs. I find the roots are more inclined to come up than to grow down. When potting is finished tie up the leaves and place the plants in a temperature of 65° to 70°. Give a good watering and plenty of moisture in the house. New roots will soon appear on the surface of the soil. Very few of the leaves will die except the very old ones. Care should be taken not to let the plants get dry; add a little manure water occasionally. The plant in the top left-hand corner had forty spikes. When the photograph was taken the other three had twenty-eight, twenty-six, and twenty-two.

Knotty Ash. J. SKITT.

COLONIAL AND FOREIGN FRUIT.

IT may be well, now that an exhibition of Colonial and other fruits has just been held by the Royal Horticultural

Society, to draw attention to the articles published in our numbers for August 13 (page 101) and August 20 (page 122), where a number of fruits more or less known are referred to, several of which we have an opportunity of figuring. *Appropos* of these articles and of the Christmas season we have thought that a few words on some other fruits would be interesting at the present time. Many readers of THE GARDEN are interested in foreign native fruits.

A fruit not unfrequently seen in Covent Garden is the

CHERIMOYER, the produce of *Anona Cherimolia*, a tree growing some 15 feet to 20 feet high, probably a native of the American Continent, and found in Peru, New Grenada, Venezuela, and Brazil. It is also cultivated in the Cape de Verde Islands and on the coast of Guinea. It is known under a number of names, and the fruits differ very much in character, size, and flavour. It will be recognised as a close ally to the Sweet Sop or Custard Apple referred to in the previous papers. Other species of *Anona*, perhaps not

much appreciated as the other species mentioned. A close ally to the celebrated

MANGOSTEEN of the East is the Kokum of India (*Garcinia indica*). It is a moderate-sized tree, with spreading branches, found wild and cultivated in many parts of India, especially in North Canara and to the south of the Concan. The flowers appear in November and December, and the fruits ripen in the hot season from February to April. They are about the size of a small Apple, nearly spherical, smooth, and of a dull red or purplish colour. The flesh is also of a dark purplish red, firm, and juicy. It has an agreeable acid flavour, and is eaten by the people.

It is also used on the western coast of India as an ingredient in curries. These fruits are often seen in the bazaars in a dry state, having been prepared by exposing them to the sun after removing the seeds, from which a solid fat or kind of vegetable butter is obtained called Kokum butter. The possibilities of this fruit is more for preserving than for eating in a raw state.

MAMMEE APPLE (*Mammea americana*).—This is a large tree belonging to the same natural order as the last. Native of the West Indies and tropical America, where it is cultivated for the sake of the fruit. The plant has also become naturalised in tropical Africa and in Asia. The fruit grows to a very large size, sometimes to that of a child's head. It is of a yellow colour. The outer rind and the pulp which immediately surrounds the seeds are very bitter, but the fleshy portion which lies between is sweet and aromatic, and is eaten either cut into slices and steeped in wine or made into various kinds of preserves.

ROSELLE, or RED SORREL.—The first is the Indian and the second the West Indian name of *Hibiscus Sabdariffa*, a pretty shrubby annual commonly cultivated in hot countries. The plant is grown principally for the sake of the fleshy calyces and fruits to which they are attached. These have a refreshing acid taste, and are largely used for making tarts, as well as for preserves and jellies.

A very refreshing drink is also prepared from them. Roselle jam is occasionally seen amongst collections of Indian preserves, Chutneys, and pickles in this country, but its good qualities are very little known. The large fleshy calyces are shown in the figure.

LIMEBERRIES.—This name is sometimes given to the berry-like fruits of *Triphasia trifoliata*, a spiny shrub of the natural order Rutaceæ, a native of China, but common in

GRASS WALK AND MIXED BORDERS AT ASHFIELD, KNOTTY ASH, LIVERPOOL.

so well known, are the 'Sour Sop (*Anona muricata*) and the Bullock's Heart (*A. reticulata*). The Sour Sop of the West Indies is a large fruit, sometimes weighing over 2lb. It is of a greenish colour, somewhat heart-shaped, and is covered with prickles. The pulp is white and has an agreeable flavour. The Bullock's Heart is a native of the West Indies, but is cultivated also in the East. The pulp is yellowish, and, though generally eaten in the tropics, is not so

gardens throughout India, into which country it has long been introduced. The fruits are about the size of a small Hazelnut, and have a red skin and an acid pulp. They are generally eaten by the people in Southern and Western India, and are also frequently used in conserves and pickles, besides which they are very often mixed with Chinese preserved fruits.

JOHN R. JACKSON.

Claremont, Lympstone, Devon.
(To be continued.)

NOTES ON HARDY PLANTS.

CYCLAMEN LIBANOTICUM.

FOREMOST among hardy species for size and effective display, and doubly valuable on account of its welcome habit of flowering in midwinter, this Palestine Cyclamen has proved an acquisition indeed, and one cannot too strongly recommend it for rockery planting, the warm border, and particularly for the alpine house, where its flowers could expand whatever the weather outside. It is absolutely hardy and exceedingly free flowering. Old and large corms, though not always the best in the genus *Cyclamen*, yield pretty tufts of sweetly fragrant flowers of extraordinary size, and smaller corms, equally floriferous, are not far behind in size of blossom. The leaves are very stout, rounded (cordate-acuminate), and marked with a white horseshoe-shaped zone, and they occur in handsome tufts. The flowers are 6 inches high and nearly 1 inch across, varying a little in colour, but generally palest pink, with deep rose petal tips and crimson spotted throat. Its sweet fragrance is remarkable in an alpine house on a sunny morning in midwinter, and just as pleasing, but not so powerful, in the open. It succeeds admirably here in half shade thrown by Poplars, and the subsoil is dry in summer and wet in winter, conditions that appear to suit the *Cyclamen* well. It grows well in harsh clay soil, with leaf-soil added, and, so far as I have been able to test with other soils, it does not appear to be difficult to grow anywhere. I have had it under cultivation in quantity for two years and a few bulbs for three years, and these have increased in size and ripened seeds where undisturbed.

Colchester.

G. B. M.

NOTES FROM A NORTHERN GARDEN.

The winter and spring of 1903-4 were in my garden on the west coast of Ross-shire as favourable as any such seasons could possibly be for the welfare of exotics; there was neither the intense cold of the early spring of 1902 nor the never-ceasing hurricanes and floods at the same period of 1903, and thus I have next to no casualties to report. A heavy snowfall without wind early in December broke a few of my shrubs, particularly a fine *Andromeda arborea*, which still retained its beautifully tinted leaves, and my big Japanese *Loquat* lost several boughs; some of the *Phormiums* had a portion of their leaves bent over; but otherwise everything has pulled through extremely well.

Although it is only three or four years since the Japanese garden was reclaimed from a wild state of nature it has made rapid strides, and is now a most civilised little spot. It is just a glade in the plantation, close to the salt water's edge, and one is struck at once by its very foreign look, chiefly owing to its *Cordylines*, *Palms*, *Bamboos*, *Eucalypti*, and *New Zealand Flaxes*. Why does not everyone start growing *Phormiums* and *Bamboos* when they are quite as easy to grow as the *Laurels* and the *Privets*? Anything handsomer than giant clumps of either of these I cannot imagine. I have the former in great variety—the green leaved form from the New Zealand swamps, the silver striped, two kinds of gold striped and banded, the purple *Phormium*, and two dwarf kinds which I am told grow on hard ground in their native land; one of them, *Phormium Colensoi*, is a perfect gem, which everyone should have; nothing injures it, as its

shorter leaves never get bent or broken over like those of its big sisters.

Of *Palms* I think I can speak with some authority, having grown them out of doors for 30 years, and I have never known one of them in the slightest degree injured by wind or weather. I started with a little bag of seed of what was said to be *Chamaerops Fortunei* from Japan. The seedlings came up like Mustard and Cress; but, though I guaranteed them hardy, I could find no one with sufficient faith to relieve me of my surplus stock. I am trying *Chamaerops excelsa* and *Chamaerops humilis*, and they also appear to be quite hardy. My two *Drimys* (both *Winteri* and *aromatica*) are most thriving bushes, and so are the *Benthamsias*, *Abelias*, *Daphniphyllums*, *Metrosideros lucida*, &c.; my *Chilian Fire Bush* (*Embothrium coccineum*) is coming on grandly, and in another year I shall expect it to show its fiery blossoms. I rather think that (like *Davidia involucreata*) it is the only one of its kind in the North Highlands, but last year I saw a fine specimen on the shores of Lough E-ke, in the Highlands of Donegal, which flowers profusely.

I made with great pains this last winter special places for *Bamboos*. Would that I could make them proof against field mice and voles, who gnaw them clean through, mistaking them, I suppose, for sugar canes! I have made the pits very deep, with alternate layers of black peaty earth, manure, decayed sea-weed, bone-dust, and old lime mortar. I have placed them in nooks in the wood, with the trees cut out to allow the rays of the sun to strike straight on them. A year or two will prove if I have done my work well, and I shall be much disappointed if my *Bamboos* do not grow into giants.

How time changes things! In 1864 I was planting these bleak shores with *Firs*, &c., and everyone shaking his head and prophesying nothing would ever grow on the exposed promontory in the thin covering of sour peat upon wet rocks. I must say I often felt very doubtful as to the results, and never dreamed that I would live to cut down trees 50 feet high, and to be tying up home-growing *Eucalypti* to home-grown *Bamboo* stakes (which we have been actually doing of late).—Extracted from notes by OSGOOD O. MACKENZIE in the *Glasgow Herald*.

CHRYSANTHEMUMS.

NEW VARIETIES.

TO prove of assistance to those who have not had the opportunity of seeing and judging for themselves I append a list of varieties which have come under my notice and are unquestionably of great merit. Though there are, undoubtedly, several others also worthy of a trial, I refrain from mentioning any except those which I am able thoroughly to recommend. All who wish to maintain a really up-to-date collection must add and discard annually.

Mrs. W. Knox (Australian).—This is a fairly large, pleasing flower, solid, with broad, recurving florets. The colour may be described as a clear chrome-yellow.

George Hutchinson (Penford).—An acquisition to the deep crimson varieties. It is an improvement in form and size on the variety *Violet Lady Beaumont*, which, in regard to size, has not come up to expectations.

Mrs. A. H. Lee (N. Molyneux) is another very large crimson flower. It was thought much of at the Crystal Palace show. The florets are of great length for a crimson, and the flower very full.

Lady Leonard (Jones) is an incurved Japanese variety of a rich golden amber shade, a flower of good form.

Miss Mona Davis (Penford).—This is a lovely flower of a creamy white shade, said to be easily grown, good both early and late, and is of dwarf habit.

Algernon Davis (Davis) is described by the raiser as a bronze *F. S. Vallis*, though I understand it is a seedling. It has just the form of *F. S. Vallis*, and will no doubt prove a valuable acquisition.

Mrs. Charles Davis (Davis).—This is the last of a trio of the same family name. It created some sensation at the Crystal Palace show on account of its fine form and magnificent colour, which is the deepest gold yet seen. The raiser calls it an improved form of *Duchess of Sutherland*.

Walter Jinks (Jinks).—Here we have a grand flower of a rose shade. It is of fine form, large, and deep, and is built up of loosely curling florets. Colour silvery rose.

W. Wilson (Jinks).—Rich crimson amaranth, best described as an improved form of *Pride of Madford*.

E. J. Brooks (Wells) is another of the same rich colour as the preceding, and is a splendid acquisition in every way.

Mrs. D. Willis James (Australian) is bright red, with golden bronze reverse, a flower of moderate width, but great depth. Perhaps its best quality is its bright colour.

Mrs. J. Dunn (Wells).—A very large flower, with drooping florets of great length. The ground colour is golden buff, and the whole flower is suffused with shades of salmon and rose. Very fine.

Marshal Oyama (Davis).—A large, solid flower, with strap-shaped florets. The colour is distinct, buff overlaid with chestnut. A variety that will find many admirers.

Leigh Park Rival (Penford) is a large, solid flower of a rich orange, shaded bronze. Should prove a good exhibition flower.

Lady Curzon.—If not one of the largest, it is certainly one of the choicest of the season. Colour clear citron, with flushes of red; the florets hang most gracefully.

Mrs. R. C. Pulling (Jones).—A large flower of fine form and finish. The florets, though only of medium width, are of good substance, and droop gracefully. Colour white, overlaid with rosy pink.

Miss Elsie Miller (Mileham).—Creamy white, shaded with bright pink. Flowers large, and of fine drooping form.

Chrysanthemiste Montigny (Calvat).—A list of new introductions would not be complete without mentioning this really fine variety. Very large. The florets are of great length, and a clear canary yellow colour.

Mrs. C. Beckett (Davis).—A magnificent variety of the purest white. Of immense depth, lasting a long time in beauty. The plant is dwarf, and very robust. Good for any purpose.

Elstree.

E. BECKETT.

MARSHAL OYAMA.

This is one of the most recent and promising additions to the Japanese *Chrysanthemums*. Mr. Norman Davis has sent me a flower that impresses one with its undoubted value for exhibition. It is very large, having fairly long and broad florets of good substance; it is of great breadth and depth. The colour is bright and attractive, and may be described light crimson on golden ground, with a bright golden yellow reverse.

ALGERNON DAVIS.

Among the many good Japanese novelties of the present season this certainly has claims to distinction. The flower submitted to me by Mr. Norman Davis is very pretty. The petals are long, and broad to medium in width. The latter build a full flower of drooping form, the petals twisting and curling in a distinct manner. The colour is not the least of its charm, this being bright yellow at the base of the petals, heavily suffused or rather overlaid with light crimson at the ends, with a golden yellow reverse. A promising variety.

D. B. CRANE.

PHENOMENAL SUCCESS OF AN INCURVED CHRYSANTHEMUM EXHIBITOR.

Now that the exhibition season is over it is interesting to note the achievements of some of the leading growers of the *Chrysanthemum*. Mr. W. Higgs of The Gardens, Fetcham Park, Leatherhead, has had phenomenal success: in fact, he has been invincible. At Portsmouth show this grower

secured first prize for twenty-four Japanese and twenty-four incurved, and on the same day at the Crystal Palace he secured the premier position for twenty-four Japanese in a competition of seventeen entries, first prize also for thirty-six incurved in the Holmes Memorial class, first prize also for six vases of incurved (each containing six blooms), and first prize at the same show for twelve incurved, distinct. Mr. Higgs followed up these successes by winning first prize for twenty-four incurved and twelve incurved at the great Sheffield show, also winning first prize for twenty-four incurved at Bradford on the same day. He also secured leading honours and silver cup at Bolton for twelve Japanese and twelve incurved. At the same time first prize respectively for twenty-four Japanese and twenty-four incurved together was won at Manchester show by Mr. Higgs, which award also gave him the Earl of Derby's Silver Challenge Cup. This is an achievement of which anyone might well be proud, and is a striking testimony to this grower's system of culture.

SINGLE CHRYSANTHEMUMS.

THE most gratifying fact in connexion with the cultivation of the Chrysanthemum is the increasing interest now shown in decorative sorts of all types. The single-flowered varieties that were only lightly esteemed rather more than a decade since are now regarded as of the greatest value. There is infinite variety in this type of the flower, both in colour and form, and as they may be had in bloom from September until December, or even later, the plants have a value excelled by no others. The severely disbudded flowers that are usually staged at the Chrysanthemum exhibitions are apt to lead the inexperienced to think they are very formal and stiff. As a matter of fact, they are the opposite, but the plants must be grown more freely. Numerous sorts have an excellent habit of growth, being bushy and sturdy, developing a display of dainty blossoms in elegant sprays. For house decoration the singles have a special value.

One may cut often without materially interfering with the beauty of the plants, new buds and other partially developed ones continuing the display. The exhibitions seem to miss the mark altogether. Nothing that I have ever seen in the competitive classes at the leading shows has been sufficiently attractive to induce outsiders or others to take up the cultivation of this type for decorative purposes. The terms of the competitions appear to need complete rearrangement. One or two of the leading trade specialists have illustrated how these flowers should be set up, and if classes were instituted in the schedules on these lines much good would be done.

The general impression appears to be that the Japanese and incurved varieties should largely preponderate at the Chrysanthemum shows now held each season. While this idea continues to be so rigidly held no real progress can be made. Even with our vase classes, which must be regarded as a step in the right direction, the shows are monotonous in their arrangement. So few persons after all can find a decorative use for these large blooms that exhibit the highest cultural skill.

The freer displays of the singles are calculated to change much of this monotony. If the

Chrysanthemum societies throughout the United Kingdom would only take a broader interpretation of the object for which they were created, viz., "to promote the cultivation of the Chrysanthemum," the chances are that the single-flowered and other decorative sorts would receive a far larger share of attention than is now the case. The singles will last for two or three weeks when used in a cut state, and they make admirable bush plants.

As the days begin to lengthen in late January and February cuttings should be inserted of all sorts that are available. During March and succeeding months they may also be propagated with success, making excellent plants from this later propagation. In almost every other respect their treatment should be identical with that of

condition. These plants were lifted in mid-October, and since that time have been standing in a cold greenhouse.
D. B. CRANE.

WORKERS AMONGST THE FLOWERS.

MR. J. D. PEARSON, of the well-known firm of nurserymen, Pearson and Sons, has been for many years an enthusiastic and very successful grower and exhibitor of the Narcissus, and is also a successful cross fertiliser. His first efforts in this direction, dating from about 1887, gave him much needful experience as to what particular varieties were best to use for pollen and seed bearers, and he is now beginning to reap excellent fruits of his labours. Among his new seedlings may be mentioned Florence Pearson, Alert, and Lowdham Beauty, and many more are coming on, from which even greater things are expected. Mr. Pearson is an active and much-valued member of the Narcissus committee of the Royal Horticultural Society, and is also a member of the sub-committee appointed recently to make suggestions for the revision of the classification of the Narcissus. A seller of bulbs is much tempted to fall in with the popular notion that "big things" in Daffodils are necessarily the best; but Mr. Pearson does not allow his artistic sense to be thus over-ridden, and he is an advocate for beauty and refinement in a flower rather than size.

MR. J. DUNCAN PEARSON.

GARDENING OF THE WEEK.

FLOWER GARDEN.

THE SHRUBBERIES.

WHERE there is much pruning to be done a start must, perforce, be made now. In many establishments there is always a great demand for quantities of evergreens, not only for home decorations, but also for the Christmas celebrations at the parish church, the various local charitable institutions, &c. The cutting of these supplies will probably more than serve to keep all the stronger growing evergreens within the desired limits. Much judgment is required, and the actual work of cutting the branches should be only entrusted to the most reliable men, or ill-balanced specimens and stumpy shoots will be the result.

other types of the flower. It is an excellent plan to plant out in a good open position in the garden a number of plants in variety. These pieces as a rule make handsome bushy specimens, and should be lifted when the buds are well set and transferred to pots, boxes, or any convenient receptacle. A good watering in and shade for a few days will suffice to establish such plants, and from treatment of this kind a free display of welcome blossoms invariably results. Plants treated in this way are very easily managed, the saving in labour alone being considerable. At the time of writing (the 1st inst.) we have plants of Miss Mary Anderson (blush white) and its buff-yellow sport Miss Annie Holden in the pink of

The hedge prunings and any that are not required for the above purpose should be burnt, making use of a smother fire, which will not only yield considerably more valuable ash than a blazing fire, but is also incomparably safer, and by its use the prunings and litter may frequently be consumed on the spot, saving the labour of removal. Many of the shrubs, especially the flowering kinds, which have occupied the same positions for any length of time, will be the better for a dressing of manure. Where it will not be too much in evidence, this may be applied as a mulching, but otherwise it should be lightly forked in. Any gaps at the front may be filled with surplus plants of Wallflowers, Polyanthus, &c.

LAWNS AND WALKS.

Frequently rolling the lawns and paths serves to impart a trim appearance to the garden and to tide over this dull and comparatively uninteresting period. During showery weather the gravel walks should be inspected, and those places the rain water collects in marked for early attention. Unless it is intended properly to drain a considerable stretch of walk, these patches should be dug up to a good depth. If the subsoil is of a close, retentive nature, it should be removed and replaced with broken brick, clinkers, or the like, replacing and rolling the gravel. Tiles inserted edgewise by the sides of steep paths will prevent most of the "washing" during heavy rains. Catch-pits must now be frequently cleaned, and floating leaves and twigs removed from the entrance to the overflow of all ponds.

CARNATIONS.

As soon after frost as the soil has become moderately dry, the plants should be pressed firm. Occasionally during the winter cats will eat the growths, and any otherwise unexplainable damage may be traced to the same cause.

A. C. BARTLETT.

Pencarrow Gardens, Bodmin.

INDOOR GARDEN.

VIOLETS.

THESE plants in frames now require air in abundance, and decayed leaves should be picked off. Unless there is a likelihood of 5° to 6° of frost, do not cover the frames, for during mild weather this has a tendency to create damp. The application of water to the roots is seldom necessary until the New Year, but, when essential, select a fine day and apply tepid water in the morning, the plants afterwards being left fully exposed all day. In the case of plants growing in heated pits water will be required more often, and there will be no dampness if the lights are tilted a little both day and night. Plants that are grown under the latter conditions are not the best from which to propagate the next year's stock, so immediately they have done flowering throw them away, and use the pits for another purpose.

CLIVIAS,

which are given a position in a perfectly cool house, must not have much water at the roots, although it would be a mistake to let them get very dry. Excess in either case will cause their leaves to decay at the tips. A night temperature of 40°, with a rise of 5° to 10° in the day, will suit them very well. Here they can remain until the New Year, when any number of plants to suit requirements can be introduced to a warmer temperature, and be given more moisture to induce them to produce their flower spikes.

CHOISYA TERNATA

that until now has been kept exposed to the frost may be brought into the forcing house; a viney that is just being started is an ideal place. When in good foliage and in full flower, this plant associates well with those of a deciduous nature, such, for instance, as Ghent Azaleas, Prunus, Lilacs, &c.

SOLANUMS.

At this dull season these soon become infested with green fly, and require occasionally to be fumigated. Select a few of the finest and ripest berries, from which to obtain the seeds for sowing another year, and put these in a sheet of paper in a sunny and well aired position to mature.

CLERODENDRON FALLAX.

This must now be pruned hard back before placing the plants in a moist warm temperature to grow. Those raised from seeds sown during the summer are making good progress in a position near the glass in a house the temperature of which is kept at 60° to 65°. They derive considerable benefit from an occasional dose of well-diluted sheep manure liquid.

PANDANUS VEITCHII.

This is still one of the best table plants. It should be propagated at all seasons of the year. The very small offsets are now being taken from

the base of old plants, and these are inserted singly in 2½-inch pots, in sand only, the pots being afterwards plunged in a brisk bottom-heat.

J. P. LEADETTER.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

EARLIEST POT VINES.

THE weather has not been favourable for the early forcing of these. When the vines have started into growth well the temperature should be raised to 55° or 60° on mild nights and 70° to 75° on bright days. Avoid high temperatures in severe weather, as this induces a weak growth; any loss of time is better made up later on when the berries are formed. The vines should be tied into position as soon as growth has commenced, and a little ventilation should be given every day if possible, if only for a short time. Remove all the weakest shoots that are not required, leaving only the best placed growths. Stop the shoots two or three joints beyond the bunch, according to space, and remove all bunches not required for furnishing the crop before the vines come into flower. Discontinue syringing the vines, and keep up a moderately moist atmosphere by adding fresh fermenting material to that already in use, and turn this to keep up the warmth. Damp the fermenting material occasionally with weak liquid manure. Water should be carefully given until growth has commenced, and weak liquid manure may be given occasionally, making it stronger as the vines increase in growth.

EARLY PERMANENT VINES.

These require similar treatment to pot vines. Small houses with shallow inside borders, and where it is possible to cover the roof lights with mats, give the best results, as the necessary temperature is more easily kept up without hard firing. In larger houses, where fermenting material of litter and leaves can be mixed up and turned occasionally, this will give off moderate moisture and warmth, and reduce the necessity of so much syringing. The outside borders should be covered with a good depth of leaves or Bracken, and spare lights placed over to keep off heavy rains. Old rods may be tied into position, but tie down the points of young vines, which have not been forced before, to induce a regular break. A little ventilation should be given on all favourable occasions. Early Muscats, from which ripe Grapes are expected in June, should now be started, and given 5° higher temperature than the above, with similar treatment in other ways.

LATER VINES.

The pruning should be pushed forward so as to give the vines as long a rest as possible. If they are clean very little loose bark should be removed; a good washing of soft soap is all that is necessary. If mealy bug is in evidence severer measures must be taken, the house must be carefully washed and painted if possible, the walls well washed with hot lime. All loose bark should be removed from the vines, and the rods well washed two or three times with Soz. to the gallon of Gishurst Compound. Remove all loose soil carefully from the border before top-dressing with fresh compost.

Impney Gardens, Droitwich.

F. JORDAN.

KITCHEN GARDEN.

EARLY PEAS.

It is necessary that ground for this most important crop should receive a thorough preparation. The south border should be turned over as soon as possible. If the land is of a stiff and clayey nature old potting shed refuse may be added to it, together with a liberal supply of well-prepared manure. If the ground has not been trenched for a few years it should be done for this crop. On very light soils an effort should be made to add some good loam. Ground for the main crop should also be trenched without delay. No crop pays better than this for liberal treatment. A good plan for the Pea ground is to throw out a trench just where the crop is to be sown and fill it with manure which has been mixed with good turfy loam. The growing of Peas in pots is undoubtedly on the increase,

and these Peas are always highly appreciated. Where several hundred pots can be grown many good dishes will be gathered, but it is not worth the trouble to grow less. That this method is on the increase is seen from the fact that several of the leading raisers are experimenting with a view to secure varieties that are suitable for this purpose. After a trial of several sorts I prefer Chelsea Gem and Sutton's Dwarf Forcing Pea. I have noticed American Wonder recommended for this work, but it was not a success here. It is a mistake to sow too early; the first week in January is soon enough, as a sowing then will be ready for gathering as soon as those sown in the middle of December. The soil should be prepared now and should be of a turfy nature, to which some leaf-soil of old Mushroom manure has been added. The compost should not be rich, as this promotes a rank growth. Stimulants are in good time when a set has been secured; 9-inch or 10-inch pots will grow this crop well. The pots should be placed in a cool house, and at no time should a high temperature be given them. The chief point is cool treatment, affording at all times plenty of ventilation. It is also necessary that the seeds should be sown thinly, six or seven plants being an ample number, which pays better than a thickly-covered pot. If the plants can be staked out it is a great advantage, but this entails much labour at a very busy season. A few Spruce or Birch twigs will keep the plants right, and these should be put in in good time. Procure seeds from a reliable source or only disappointment will ensue.

*Hoptoun House Gardens,**South Queensferry, N.B.*

THOMAS HAY.

ORCHIDS.

ORCHIDS AT THE GLEBELANDS, SOUTH WOODFORD.

CALLING a few days since at the above address, the residence of Mr. J. Gurney Fowler, treasurer of the Royal Horticultural Society, and well known as the home of a highly interesting collection of Orchids, we noticed in going through the houses with the head gardener, Mr. Davies, a grand lot of Dendrobiums, with well-developed pseudo-bulbs, giving promise of a great display of flowers later on. The varieties were numerous, but great batches were to be seen of *D. wardianum*, *D. thyrsiflorum*, and *D. heterocarpum*. Several specimens of the latter are now in full bloom, loading the air with delicious perfume. Mr. Fowler grows batches of Epidendrums, and there is now a group of many plants of *E. Armstrongii* in full blossom, all different and all charming. Being planted out they are far finer than usual, the flowers being particularly good. Odontoglossums are growing well here now, since more humidity has been provided for the plants. It is really wonderful what strides the plants have made in less than a year. A good batch of *Masdevallia tovarensis* was noticed in this house. This is one of the few really white Orchids of easy culture, and the flowers are always delightful. The *Cypripediums* are well done, and many were in bloom, including the best and most popular kinds, such as *C. insigne* Sanderæ, *C. insigne* Harefield Hall, *C. harrisianum* albens, *C. chikaberryanum*, *C. leeanum* giganteum, *C. fowlerianum*, and *C. Mrs. Alfred Fowler* (*lathianianum* × *Charlesworthii*). The bright upper dorsal of this charming variety is perhaps best described as a mixture of deep red and bright pink. Many others were in bloom, including a new hybrid flowering for the first time. *Cymbidiums* are a noticeable feature at the Glebelands. Grown in a cool house the plants are sturdy, clean, and full of vigour, with a promise of a wealth of bloom to come. A batch of *Cattleya labiata* in the big *Cattleya* range was just passing out of bloom, a few dozen flowers being left. The *Cattleyas* are in excellent condition. All through they are a very fine lot of plants. *Lelio-Cattleya Ilione* (*C. bowringiana* × *L.-C. dominiana* var. *Langleyense*) was in perfection. The bright, rich

crimson blossoms have a glow about them that is unapproachable in any hybrid that we know of in this way, and Mr. Fowler's variety is the finest known. ARGUTUS.

WORK FOR THE WEEK.

ONCIDIUM MACRANTHUM AND O. SERRATUM.

THE long scendant spikes of this section of *Oncidium* are now fast lengthening out, and the training of them should be constantly attended to. Tie them to a piece of string strained along the house. This mode is preferable to tying them around stakes; we find the flowers come better and have more substance, and they can easily be tied to stakes when in flower if it is so desired. Many strong roots are now being emitted; these should be carefully watched. Slugs have a special liking for them. If they are lost much of the support that should sustain the plants during the severe strain of flowering is gone. The racemes should be removed from any plants that show signs of shrivelling; if allowed to remain the flowers would be very poor and the plant nearly ruined. We have several spikes now over 12 feet long, and they will not flower before next July, so if the pseudo-bulbs were not in a very sound state, and the roots too, disaster must follow. It is necessary to water them only when they become really dry during the short dull days.

ONCIDIUM ORNITHORHYNCHUM.

This beautiful little species is now passing out of flower, and in most cases the new growth is 2 inches high. New roots are being emitted, and the necessary repotting or surfacing may be done. Use a mixture of fibrous peat three parts and one part each of sphagnum moss and leaf-soil; use ordinary pots, making them nearly half full with chopped rhizomes, pot rather lightly, and surface with moss. Give a position in the cool intermediate house. Water must be carefully applied till the growths have made more progress.

DENDROBIUMS.

Many of the semi-deciduous sorts are now fast pushing out their flower-buds, and they must have rather more water. Those that are not so forward need only enough water to prevent shrivelling. Where the practice of removing the plants to cooler structures for resting is carried out the forward ones may be taken to the warmer houses and the others allowed to remain; by this means the season of flowering may be prolonged. If growers would more generally get *Dendrobiums* in flower in January and February, instead of March and April, these Orchids would again attain the popularity they once had. The sweet-scented *D. heterocarpum* (syn. *D. aureum*) is now in flower, and proves very useful where button-holes are required. Water should be very carefully applied; very little will suffice to maintain a well-ripened plant. Another very useful *Dendrobe* for flowering now—in fact, it is in flower more or less all the year—is *Dendrobium Cassiope*. This requires rather more water than most of this section. Another one for Christmas flowering is *D. Artemis*, raised by us from *D. splendissimum grandiflorum* and *D. heterocarpum*. The influence of heterocarpum twice has been the means of bringing it naturally into flower at that season.

Gatton Park Gardens, Reigate. W. P. BOUND.

THE INDOOR GARDEN.

KLEINIA GALPINI.

FOR some years after its introduction this South African succulent was grown under the name of *Senecio Galpini*, but in the "Kew Hand List" it is placed in the genus *Kleinia*. As a flowering plant it is superior to most of the *Kleinias*; indeed, it is well worthy of increased attention as an autumn and winter-blooming plant for the greenhouse. It has been grown at Kew for the last ten years or more, but for some reason or other it is rarely if ever met with elsewhere. Out of bloom it bears a considerable resemblance to an *Echeveria*.

It forms a partially succulent upright stem, clothed with fleshy glaucous leaves. The stem in time branches freely, and the flowers come from the apex of each shoot. They are composed of a closely-packed head of florets about 1½ inches across and of a bright orange colour. Plants from 1 foot to 18 inches high flower freely. Their propagation and culture are by no means difficult if it is borne in mind that the plant is succulent, on which account cuttings need but little water, and should be placed in a dry warm structure. The spring is the best season for taking the cuttings, and the plants so obtained will flower in the autumn or winter of the same year if shifted in pots from 4 inches to 5 inches in diameter and grown in a light and airy house. In the "The Dictionary of Gardening" it is referred to as *Senecio Galpini*, and the date of its introduction from the Transvaal is given as 1892. T.

ERICA GRACILIS AND ITS VARIETIES.

THOUGH collections of Heaths embracing a hundred or more species and varieties are not to be met with now as they were some years ago, yet a few kinds are still cultivated, probably in greater

ERICA GRACILIS NIVALIS.

numbers than ever before, for they are popular market plants. One of those extensively grown for this purpose is *Erica gracilis*, which forms a pretty, freely branched little specimen, bearing quantities of tiny rosy purple blossoms. Good plants generally meet with a ready sale, especially if the flowers are well coloured, for some cultivators seem to be able to impart a richer tint into them than others. Exposure tends to deepen the colour of the flower, hence the grower who leaves his out of doors as long as possible, and chances a certain amount of risk from early autumn frosts, is enabled, if his plants escape uninjured, to take flowers into the market of richest colour. Two forms of this Heath have been in cultivation for many years, one of them flowering in the autumn and early winter, and the other in the spring. Last year a new variety and a decided acquisition to autumn-flowering Heaths made its first appearance at the meeting of the Royal Horticultural Society on October 27, when an award of merit was given it. This, which bore the name of *Erica gracilis nivalis*, was shown by Messrs. Gregory and Evans of Sidcup, Kent, a firm noted for their successful culture of these greenhouse Heaths, and who have had this season a fine display of their

new variety. Its distinguishing feature is the colour of the blossoms, as they are almost pure white, and it is quite possible that the slight tinge of colour they now possess may give way under cultivation, for I believe the white variety of *Erica hyemalis* was not quite so pure when first seen as it is now. A very characteristic illustration of the new *Erica gracilis nivalis* is given herewith, the plant figured being a typical market specimen.

Besides the above the following Heaths all make their appearance in Covent Garden Market some time during the season: *Erica caffra*, a compact grower, with small white flowers in winter and early spring; *E. candidissima*, long spikes of tubular-shaped pure white flowers, late spring and early summer; *E. Cavendishi*, remarkable for its large golden flowers of a wax-like texture, at about the same season as the preceding; *E. hybrida*, red tubular flowers in spring, not so much grown for market now as it once was; *E. hyemalis*, probably grown in greater quantities than any other greenhouse Heath. It is in season throughout the winter. The variety *alba* is equally desirable with the type. It is somewhat strange that the early history of so popular a plant as *E. hyemalis* should be unknown, though it is generally considered to be a seedling from *E. limaeana*. Other market Heaths are *E. melanthera*, with small mauve-coloured blossoms, and prominent blackish anthers, winter and early spring; *E. perspicua nana*, a twiggly little bush with pure white flowers in spring; *E. Spenceri*, pink and white tubular-shaped flowers, closely packed in dense spikes, spring; *E. ventricosa*, represented by several forms, is a summer Heath; and *E. wilmoreana*, which comes in as a succession to *E. hyemalis*, and like that well-known kind its origin seems to be doubtful.

As illustrating the great changes that occur in the horticultural world, it may be mentioned that in the "Practical Gardener," by Charles McIntosh of Dalkeith, published in 1840, we read under the heading of "Greenhouse Plants": "*Erica* is a genus so popular it would be vain to make a selection. Where there is any attempt at collection there should not be less than from 200 to 300 species of this family." Anything approaching that number would be impossible to obtain at the present day, though I see in the catalogue of the one time prominent nursery firm of E. G. Henderson and Son of Wellington Road, St. John's Wood, for 1875 no less than 133 species and varieties are enumerated. The most recent "Hand List" of these plants at Kew contains eighty names. H. P.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A FRUIT GROWERS' UNION.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Your leading article of the 3rd inst. giving an account of a new society formed for the mutual benefit and protection of the fruit growers in the Vale of Evesham interested me greatly. Much credit is due to the Evesham fruit growers for the public spirit shown by them in forming this combination, and everyone interested in fruit growing will wish them all possible success. The question of the disposal and the advantageous marketing of fruit, flowers, and vegetables lies deep at the bottom of the failure of the hardy fruit industry of England, and until this question is settled more to the grower's advantage so long must the industry remain in the deplorable and chaotic condition of unprofitableness it has always been in. We are never tired of boasting that the climate and soil of England is as suitable for the successful growth of fruit as any country in the world, and it is true, and yet growers cling to the obsolete system of disposing of their crops through the middle-man or an agent whom they possibly do not know and over whom they have no control. Frequently in congested markets—e.g., Covent Garden—where crops are often

dumped down in a glutted market and disposed of at ruinous prices to the grower, they barely pay the price of carriage. This is not to be wondered at when we reflect that the accommodation at Covent Garden is very little better or larger now than it was when first built years ago, when it dealt only with the home-grown produce of that day. It was then often in a congested condition: what must it be in now, with the fruit expansion which has taken place in the home trade, to say nothing of the immense and annually increasing foreign imports, most of which find their way to Covent Garden! The grower is perfectly helpless in the hands of his agents, whose charges are seldom less than 15 per cent., including market toll, commission, and other minor charges. Indeed, they are often much more. What makes the grower's position so helpless is that he has absolutely no control over the disposal of his produce. To the few large growers who have stalls of their own in the market it is different, as they can look after their own interests; but the majority are at the mercy of the state of the market.

So long as this state of things remains so long will the industry continue in a half-hearted, halting, and starving condition. It is clear that if all the growers would combine and form a union to dispose of their own produce to the public and to retail dealers in all large centres of population without the intervention of the middle-man that this industry would soon become one of the most prosperous in the land, to the great benefit of the grower and the public. To the former because the method would to a great extent prevent dumping in congested markets, and secure to them fair and remunerative prices, and to the public because they would receive their fruit and vegetables at first hand, clean, fresh, and in a more attractive condition, and, moreover, no doubt at less cost.

This question appeals to the owners of land even more forcibly than it does to the growers, as the fruit trees, generally speaking, are their property. So no great difficulty should be found in finding money to start a national society on the same lines as that formed at Evesham, having centres in all counties and large towns. Every industrial interest in these days has its union or society co-operating for benefit and protection, and until the fruit culture in England is similarly represented it will never reach its high water mark, and for this there is no one to blame but the growers and the owners of the land.

A FRUIT GROWER.

VIOLETS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I invested in a few plants of the new single Baroness de Rothschild this year, described as the largest of the giant Violets. I imagine it is a selection from *La France*, but I can see very little, if any, advance in size, and my plants are evidently not all true, as there is a quite inferior variety among them, although they were obtained from one of the best sources. John Raddenbury, although not a large flower, is a distinct novelty and takes my fancy very much. It reminds me of the wild Dog Violet, but with the advantage of fragrance. A little bunch of John Raddenbury makes as pretty a button-hole as one can wish for. *Apropos* of this, I wonder when the florists will learn how to make up a button-hole of Violets, and when people of otherwise good taste will refrain from purchasing and wearing the congested abortions which are to be bought at the shops. No more than eight to ten good flowers should be used for each bunch, and every flower should be properly seen.

The man who could introduce a good single white Violet would be a public benefactor, for at present we have nothing worth looking at. The blues have been advancing for years, but the white ones seem to have stood still. Imagine what a beautiful flower a white Violet of the size and shape of *La France* or *Princess of Wales* would be. Of the doubles I think Mrs. Astor is my favourite, although it may not be so useful to the market grower as *Marie Louise*. It is very

taking in colour, and the perfume is most pronounced and delicious. Comte de Brazza I have reluctantly had to give up; it is such a bad grower and shy in flowering. I should think that these are common complaints against it, for how rarely is it seen in good form, even in gardens where the very choicest flowers are to be obtained, and where, to the customer, price is no object. I should be very glad to know how to grow and flower this Violet well.

Rgr.

F. H. C.

LATE PLANTING OF DAFFODILS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I should like to add my experience on *Narcissus* (page 308 of *THE GARDEN*, the 3rd inst.). I planted in the last week in January, 1902, Sir Watkin, Emperor, and Empress, which all gave a beautiful display, and the flowers were almost as fine as those from bulbs planted in November, but the advantage I found from this late planting was that the flowers were quite a fortnight later. The bulbs were kept in a very cool shed all the winter. This stopped them starting into growth. J. S.

BENTHAMIA FRAGIFERA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The question was recently asked in your columns if this tree would produce fruit without being grafted. I am therefore sending you some fruiting branches taken from a seedling tree, of which an illustration was published in *THE GARDEN* a few weeks since. Those trees are now (the 8th inst.) heavily laden with their beautiful berries. Birds, however, are very fond of them, so that it is very difficult to preserve them till they are perfectly coloured, especially after the severe weather we experienced at the end of November. I know of no shrub that grows and fruits so freely from seed as the *Benthamia*, equally beautiful with its blossoms in May, or laden with fruit in November and December. Almost any soil or situation suits it so long as it is not subjected to more than 8° or 10° of frost.

Trelissick, Truro.

WILLIAM SANGWIN.

INSECT PESTS AND DISEASES.

BLACK-LEG OR POTATO STEM-ROT.

DESCRIPTION.

ALTHOUGH known for some time on the Continent, this disease has not been prevalent in Great Britain. There is reason, however, to think that it is spreading in this country. It is very destructive, and the loss caused by it in Germany is frequently 10 to 15 per cent., and sometimes 75 per cent. of the entire crop.

The leading symptoms of the disease are as follows: The leaves wilt and turn yellow; then they become shrivelled from below upwards, and finally die. If the underground portion of the stem is examined when the leaves commence to droop, its surface will be found to be more or less covered with brownish stains. This discolouration gradually extends up the stem, which finally becomes black and rotten throughout. The number of plants affected in a Potato field varies very widely. Diseased plants may be found growing among perfectly healthy ones, but more frequently the disease spreads from one plant to another.

The disease is primarily caused by a bacterium called *Bacillus phytophthorus*, but as decay proceeds various kinds of fungi, e.g., moulds, &c., assist in the completion of the work. The disease spreads with greatest rapidity during hot, damp weather, and is most abundant during the months of June and July. The death of the haulms at this early period of the season, especially in the case of late varieties, means serious loss, not only on account of the scanty crop, but because the tubers also become infected by the bacteria that have been washed into the soil from the rotten haulms.

METHODS OF DEALING WITH THE DISEASE.

The following measures have been suggested by Dr. Otto Appel, who has studied the disease in Germany: (1) Potatoes, as well as Beans, Carrots, Turnips, Cucumbers, Vegetable Marrows, Sugar-beet, and Mangolds, which are also susceptible to the disease, should not be cultivated for two years on land where the disease has occurred. (It has been experimentally proved that cereals are not susceptible.)

(2) Potato "sets" should not be cut, but the tubers should be planted entire.

(3) Care should be taken to obtain seed from districts where the disease does not exist.

(4) Lime, or strong nitrogenous manures, especially nitrate of soda and sulphate of ammonia, should not be used.—*Board of Agriculture and Fisheries' Pamphlet.*

THE CANKER FUNGUS.

THERE is probably no disease to which fruit trees are subject the nature of which is so generally misunderstood, or any disease for which so many others are mistaken as that of canker. This want of knowledge among gardeners generally is not confined to this country, for even in scientific Germany the term *krebs* and in France the term *chancre* are used in the same loose way. Every kind of gaping wound in the bark, especially if there is a swelling round it, or even a swelling on the bark without any obvious fissure, is spoken of as canker, though such may be, and often are, due to cuts made in the bark by careless pruning, to damage by hailstones, improper or excessive pruning, badly drained or unsuitable soil, excess or deficiency of certain essential plant foods, and, most commonly of all, to hypertrophy, or excessive sap formation caused by the irritation of colonies of woolly aphis or American blight. The amateur may well give up and say that the assignment of the proper cause to these fissures and swellings is beyond him. But he may take heart, for, with a very little knowledge of the real canker fungus, he can easily identify it, and by a little timely aid prevent the ruin of some of his trees. Real canker—not the thing that looks like it—is caused by the growth of a fungus known as *Nectria ditissima*. The causes mentioned above, to which swellings and malformations are often due, are often also the cause of canker to this extent, that by the cracks and fissures they produce in the bark a suitable nest is afforded for the development of the spores of the fungus.

The nature of this fungus may be best understood by comparing it with mildew. Everyone who has examined mildew at all carefully will have seen that it consists of two parts, a network of delicate fibres ramifying in all directions, known as the mycelium, and rising from this a multitude of shoot-stems of infinite fineness bearing on their ends the familiar spore cases, which, when the mould is brushed or shaken, produce a cloud of dust—the spores. When a spore of the canker fungus is conveyed in any way to a suitable spot on or in the bark of an Apple tree—wounds or fissures of any sort mainly—it produces a mycelium which penetrates the rind and wood, and lives upon the juices of the tree. It grows very slowly, but after a time causes swellings or distortions of the bark, and later, when the mycelium has sufficiently permeated the tissues, the portion of the branch above the seat of infection dies. The growth of the fungus is accompanied by preparations for the propagation of itself, which take the form of the production of spore-bearing cases, on the surface of the rind of young branches, or more often, in the case of older branches, on the inner surface of the wood laid bare by the fissures. These perithecia are crimson in colour and are clearly visible to the naked eye, being usually disposed in groups. Sometimes a protuberance as large as a hen's egg may be seen with all the cracks on it literally filled with these crimson spore cases. Wherever the canker fungus has had time to develop these will be found, and thus furnish unmistakable evidence of its existence, and always enable us to distinguish it from the other diseases which are so often mistaken for it by those in ignorance of this simple diagnosis.

When we come to consider the methods of prevention and cure, the most obvious thing to do is carefully to examine all young trees purchased, or grafts obtained from neighbours. On young twigs the traces of the fungus, if present, are necessarily extremely minute, and any suspicious places should be closely examined with a pocket lens for signs of the crimson spore cases, it may be only one or two, in some minute crack. As the infestation is easily spread from tree to tree it is a good plan to cut out infected branches altogether and burn them, or if the whole tree is infected, to destroy it. Where this is not desirable, the affected parts should be cut clean off with a sharp knife and tar applied to keep out spores and give the wound a chance of healing up. This has sometimes been done successfully when a branch has been diseased nearly a third of the way through. Syringing infected trees is a great check to the spread of the fungus, though not a cure, as it would kill the spores and spore cases, but would leave the mycelium untouched. The spraying should be done two or three times during the winter, all the obviously infected spots being given an extra dose. A strong solution for this purpose can be made with 20lb. of sulphate of copper to 100 gallons of water. A solution little if any less effective is the caustic solution with which trees are sprayed in the winter to remove mosses lichens, &c. This is made by dissolving 1lb. of ground caustic soda and 1lb. of crude commercial potash in 10 gallons of water, to which is added 1lb. of soft soap to ensure a more thorough wetting of all parts.

This spraying, however, can never be more than a partial remedy, though it will do much to check the introduction of the fungus into orchards and prevent the spread of it from tree to tree. Still, for a complete cure, dependence must be placed upon the surgical methods, or even total extinction of trees badly infected. Trees should be always kept clear of lichens and mosses by the use of the caustic solution referred to above, while woolly aphids, which are not only injurious in themselves, but are the means of conveying the spores from tree to tree by their fleecy coverings, would be largely reduced by the same winter washing.

Some varieties of Apples are more liable to this disease than others, Ribston Pippin being notoriously subject to it, though, by grafting on the Paradise stock and frequently lifting it can be enabled to make a better stand against it. Lord Suffield, Cox's Orange Pippin, Golden Pippin, and varieties of Reinette are also specially subject to it, though not to such a degree as Ribston Pippin. Although the canker fungus has been spoken of as a disease of Apple trees only, it must not be understood that it is confined to them. It also affects Pear trees considerably in some places, and in a less degree Plum trees. On the Continent it is much more prevalent than in this country, being as common on Pears as on Apples.

ALGER PETTS.

SOCIETIES.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE late exhibition of this society was held last week at the Crystal Palace. The following is a brief report:

Twenty-four Japanese blooms: First, Mr. J. Simon, gardener to W. W. Mann, Esq., Ravenswood, Dextley. Dorothy Pywell (white Japanese, with curling florets) was very good. Mr. W. Jinks, gardener to L. Drew, Esq., Knowle Green House, Staines, was first for twelve Japanese blooms; second, Mr. John Simon; third, Mr. C. Harris, The Grove Gardens, Watford. Mr. G. Prudden-Clark, Hitchin, won the first prize for six Japanese blooms, distinct, Mr. C. Bellis, Fonthill Lodge Gardens, Forest Hill, being second. For twelve incurved blooms, in six varieties, Mr. John Simon was first with some good flowers of Frank Hammond and others. Mr. W. C. Pagram, The Whim Gardens, Weybridge, was first for six bunches of large-flowered single Chrysanthemums with a pretty display. The second prize was won by Mr. James Brookes, Totteridge Park Gardens, Herts. An extra prize was awarded to Mr. C. Brown, Abbott's Langley.

For six bunches of small-flowered singles Mr. W. C. Pagram was first. Mr. W. G. Prudden-Clark won the first prize for six Japanese blooms in four varieties, and he was also first for six bunches of any variety. The best vase of Chrysanthemums was shown by Mr. Clark.

The first prize for twelve vases of Japanese blooms in six varieties was taken by Mr. Charles Harris, The Grove Gardens, Watford. General Hutton and others were very good.

The best group of Chrysanthemums and other plants was set up by Mr. W. Howe, Park Hill Gardens, Streatham, Mr. Robert Foster, Nunnhead, being second.

The first prize for a vase of Pompon Chrysanthemums was won by Mr. D. B. Crane, Highbate. Mr. Crane also showed the best basket of Chrysanthemums.

The first prize for a vase of Chrysanthemums, with foliage and Grasses, was won by Mr. H. Pestell, Elstou. For six Japanese blooms, distinct, Mr. C. Haselgrove, Sydenham Hill, was first.

Mr. Prudden-Clark was first for six bunches of Japanese, distinct. Mr. Charles Brown, Langley House Gardens, Abbott's Langley, being first for six bunches of decorative sorts with a charming lot. Mr. Crane won for six bunches of small-flowered Pompons. Mr. Charles Harris, The Grove Gardens, Watford, was first for a vase of Chrysanthemums and foliage with handsome blooms.

Mr. W. Howe, Park Hill Gardens, Streatham Common, S.W., won the first prize for a table of plants with a pretty lot. *Callicarpa purpurea* with its purple berries was very bright.

TRADE EXHIBITS.

Mr. David Ingamels, King's Grove, Maidenhead, showed Potatoes in all the most famous sorts (silver medal); Messrs. John Laing and Sons, Forest Hill, exhibited excellent hardy fruit (silver medal); Messrs. Goulben and Fletcher, 6, Ashley Road, Altrincham, had a charming exhibit of single Chrysanthemums (silver medal); Messrs. J. Cheal and Sons, Crawley, showed some richly-coloured Apples and some good dishes of Pears (silver medal); Messrs. H. Camell and Sons, Swanley, made a brilliant display with Begonias, Celosias, and Pelargoniums, the latter very attractive (gold medal); Messrs. Ambrose and Son, Chesham, exhibited Free Carnations, cut Roses, the new black Grape Melton Constable, as well as pot plants of Cyclamens, Heaths, &c. Tubs for shrubs were sent by Messrs. Champion and Co., 115, City Road, E.C. Mr. Williams, Ealing, sent rural table decorations.

The Pattison Patent Lawn Boats were shown by Mr. H. Pattison, 1, Farn Avenue, Streatham.

On Monday evening last the executive committee of the above society held a meeting at Curry's Restaurant, Strand, when Mr. Thomas Bevan occupied the chair. In the absence of Mr. Richard Dean through illness, his place was taken by his son, who read the minutes of the previous meeting and the correspondence. A rough financial statement was submitted, showing income received to the amount of £730 odd, inclusive of the amount payable by the Crystal Palace Company towards the November show. A list of the medals awarded at the December show was then read and approved. A proposal was made to the effect that the duties of the classification committee be embodied in those of the floral committee, and it was resolved that it should go before the annual general meeting. On the motion of Mr. C. H. Curtis a sub-committee was appointed to consider the advisability of organising a conference upon early varieties at the October show in 1905. The gentlemen appointed were Messrs. D. B. Crane, C. H. Curtis, Hawes, Such, and Moorman.

Some discussion ensued upon the need for having an occasional meeting for the discussion of interesting and instructive topics relating to the Chrysanthemum, and a wish was expressed that the suggestion might take a more tangible form. Several new members were elected, and the meeting closed after a very busy evening.

NATIONAL ROSE SOCIETY.

ANNUAL MEETING.

THE twenty-eighth annual general meeting of this society was held on the 8th inst. at the Hotel Windsor, Victoria Street. There was a large attendance of members. Among those present were the Revs. F. Page Roberts, J. H. Pemberton, and R. Powley, Dr. Shackleton, Messrs. E. J. Holland, H. E. Molyneux, G. W. Cook, A. Tate, J. T. Strange, H. P. Landon, H. G. Mount, G. G. Orpen, Conway Jones, E. T. Cook, George Paul, George Gordon, W. J. Grant, C. E. Cant, B. Cant, Frank Cant, W. Marshall, A. E. Prince, W. D. Prior, J. Green, R. Harkness, W. J. Jefferies, Lewis S. Pawle, Will Taylor, Arthur Turner, Charles B. Hayward (hon. treasurer), Edward Mawley (hon. secretary), and many others.

Mr. C. E. Shea, the newly-elected president of the society, was unanimously voted to the chair. The minutes of the last general meeting were taken as read. Messrs. G. G. Orpen and H. G. Mount were appointed scrutineers of the ballot.

Before proceeding to the business of the evening the chairman said he had a very pleasant duty to perform, namely, the presentation to Mr. Mawley of a small testimonial, a cheque for 150 guineas. They all felt that any gift could only slightly show their appreciation of his services. What they would have done without Mr. Mawley, Mr. Shea did not know. Mr. Mawley, in reply, said he did not know how to express his thanks for such a handsome gift. It had always been a great pleasure to work for the National Rose Society, and to receive this fresh token of their approval was extremely gratifying. Mr. Mawley, in again thanking the members, said he had been secretary of the National Rose Society for twenty-six years. The following address accompanied the gift. Two hundred signatures were appended.

"To E. Mawley, Esq., V.M.H., Hon. Secretary N.R.S."

"We, the undersigned, on behalf of the subscribing members of the National Rose Society, whose names and addresses are annexed, beg your acceptance of the accompanying cheque for 150 guineas as a mark of their appreciation of the most zealous and efficient service which you have for so many years voluntarily devoted to the interests of our great and rapidly increasing society."

"J. H. PEMBERTON.

"ALEX. DICKSON.

"HARCOURT P. LONDON."

Mr. Mawley then read the annual report, which will appear in *extenso* in our next number.

Some discussion took place as to where the provincial show should be held in 1905. Mr. Mawley said that for various reasons the authorities at Halifax, Birmingham, Edinburgh, and Sheffield were unable to receive them. Mr. Conway Jones brought an invitation from Gloucester, which was favourably received. Mr. George Gordon, however, thought that as the society were having two metropolitan shows and were giving extra prizes at the autumn exhibition, £25 to the new hall, and in other ways were spending more money, it would be best to forego a provincial show in 1905. He moved an amendment to that effect. It found no second, however, and therefore fell to the ground. Mr. Mawley gave facts and figures to show that the society was in such a condition financially as to venture upon a provincial show, and then reasonably hope to have a good balance. Eventually the Rev. J. H. Pemberton moved "That a provincial show shall be held at Gloucester in 1905." He suggested Tuesday, July 18, as the most suitable date, and this was finally accepted. Mr. Grant seconded the resolution, pointing out how easy it was for northerners to get to Gloucester. It was carried *acut. con.*

After Mr. C. B. Hayward (hon. treasurer) had read the financial statement, the chairman moved the adoption of this and the report. He referred to the loss of Dean Hole, and said it would be impossible adequately to fill his place. He also made sympathetic reference to the death of the Rev. A. Foster-Melliar. The financial state was unique in the society's history. Whereas the balance in 1902 was only some £14, it now stood at £318. In 1900 there were 554, now they were 1,300 members. He sympathised with Mr. Gordon's caution, but Mr. Mawley assured them it was possible to do all they wished and still have a substantial balance in hand. Mr. Shea said that members were not simply passing through, for the percentage of resignations in 1904 was considerably less than in 1903. With reference to their having to remove the July show from the Temple Gardens, he said that occupants of some of the chambers had complained of the noise, but the idea of a Rose show being a nuisance came to him as a surprise. The Botanical Gardens, where the 1905 show would be held, were said by some to be out of the way, but they were much more convenient for visitors from the east and north. There was scope for greater variety and improvement, and there would also be better catering. The refreshments at the last Temple Rose show were referred to as abominable. Mr. Shea pointed out that an increasing number of members provided material for a strong committee. Mr. Jefferies seconded this resolution, which was passed unanimously.

Mr. George Paul proposed that "The new rules and regulations of the society be adopted." This was seconded by the Rev. F. Page Roberts, and after discussion of some details, was passed unanimously. In reply to a question as to whether Bye-law 8, that blooms must be exhibited in boxes of regulation size, would be enforced, the chairman replied in the affirmative. The questioner was understood to imply that this bye-law was sometimes infringed. In reply to Mr. Conway Jones, Mr. Shea said that thirty-six blooms might be staged in two boxes of eighteen.

Mr. W. J. Grant proposed that "The thanks of the society be given to the Officers and other members of the committee for their services during the year." Mr. E. J. Holland seconded this proposition, both speakers emphasising the value of the services of Mr. Hayward and Mr. Mawley. Mr. Holland also said hearty thanks were due to those committeemen who came from a distance. Carried unanimously. Mr. Mawley and Mr. Hayward expressed their thanks for the resolution and gratification that their work was appreciated. It was stated that there would probably be little difficulty in finding a place for a northern show in 1906.

In announcing the result of the ballot, Mr. Shea said he found himself elected president of the society. He said that it was so difficult that it became almost easy to succeed Dean Hole. It was so impossible to expect another president like him that criticism would be silent. He mentioned that now a president could not be elected for more than two years. He thanked them most sincerely for the honour. The newly-elected vice-presidents were Messrs. E. T. Cook, W. J. Grant, A. Tate, and Rev. F. Page Roberts. The committee members newly chosen were the Rev. H. A. Berners, Messrs. E. J. Holland, Courtenay Page, and A. H. Pearson. A vote of thanks to the chairman closed the proceedings.

THE DINNER.

At the unwelcome early hour of 5.30 the annual dinner was held after the meeting. Mr. Shea occupied the chair, and met with a gratifying reception. After the usual loyal toasts, the chairman proposed "The National Rose Society," which was responded to by Mr. Mawley. In the absence of Mr. George Bunyard, V.M.H., the Rev. J. H. Pemberton proposed "The Horticultural Press," responded to by Mr. E. T. Cook; and Mr. Gordon proposed "The Chairman." A very pleasant evening was spent by the large number of members present. Mr. Mount of Canterbury kindly sent some beautiful Roses, and Messrs. Bunyard sent fruit. The Georgian Singers supplied the music.

THE BRITISH GARDENERS' ASSOCIATION.

A WELL attended meeting of the Caterham Gardeners Society was held on Friday, the 2nd inst., to hear an address upon the "British Gardeners' Association," by Mr. R. Hooper Pearson. Mr. Pearson briefly sketched the history of the association, which was, he said, intended to be to the professional gardener what the various organisations which control other professions are to them. He quoted from articles which had appeared in the Press to support his contention that many men who had proved failures in other professions eventually drifted into that of gardening. These men were often glad to accept almost any wage that might be offered them, and this was, of course, unfair to the genuine professional gardener who had studied diligently at his calling since boyhood.

Such a condition of affairs could not exist in a properly organised profession, and it was in the power of gardeners to amend matters. Now that the British Gardeners

Association had been started, every gardener could do his share towards bringing about reform by at once becoming a member. The association would deal firmly with what were undoubtedly abuses, but it hoped generally to be able to conduct its operation in a conciliatory spirit, fully recognising that to effect permanent good the best interests of employers as well as employees must be looked after. Employers would, he felt sure, gladly welcome an organisation which would supply them with thoroughly experienced and reliable gardeners. These were the men who would be found to reduce the working expenses of the garden. Mr. Pearson then read the prospectus issued by the association.

In the discussion which followed some of the speakers stated that they had hitherto hesitated to join the association, the reason being that they had not clearly understood its programme, but that they would now become members, and a number of the audience gave in their names for this purpose.

NATIONAL POTATO SOCIETY.

FIRST ANNUAL GENERAL MEETING.

IN the Agricultural Hall on the evening of Wednesday, the 7th inst., the first annual general meeting of the National Potato Society was held. Upwards of sixty persons were present. After the minutes relating to the inaugural meeting of the society had been read by the secretary, the chairman, Mr. A. D. Hall, explained that owing to the non-receipt of the results of one or two of the society's Potato trials, it had been found impossible to complete the report of the society's work in 1964. Mr. Walter P. Wright had, however, drawn up a summary of the report, and he called upon that gentleman to read the same to the meeting.

The outstanding features of the summarised report read by Mr. Wright were that the society's show at the Crystal Palace on October 11 and 12 was a great success, and returned a profit to the society; that an audit taken of the varieties then exhibited showed that 453 distinct sorts were staged, 270 of which, chiefly novelties, were shown once only; that the balance-sheet showed a profit on the year's work of £46 18s. 3d.; that an election among the members has been held with a view to providing interested persons with lists of standard varieties; and that the members joining the society up to November, 1964, totalled nearly 300 private members and 1,500 affiliated members, making a grand total of nearly 2,000 members. The report, which was unanimously adopted, extends to sixty-four pages, and will be issued very shortly.

Mr. A. D. Hall had much of moment to say about the Potato trials organised by the society, and his remarks were followed with deep interest. He thought that, despite the scoffers who said that trials would only show them what they already knew, a good deal of valuable information would be gathered from reports of the trials, and that the conclusions arrived at could not fail to be of benefit to farmers and small growers alike. He had gone carefully into the subject of the cost of trials, and found that it would be a heavy one. Each variety tested should, in his opinion, have two square rods of ground allotted to it, and as there were 453 varieties staged at the National Potato Society's show, and there would be supplemented by other new sorts, the society would require from five to six acres of land for testing purposes. The cost could be fairly put at £15 per acre, which was not allowing any payment for supervision, and would not be lessened materially by the sale of the produce.

After making the above remarks Mr. Hall vacated the chair to Mr. G. Gordon, under whose presidency the meeting proceeded to elect officers for the ensuing year. Practically the whole of the present officials were re-elected, the nominations of Sir John Llewellyn as president, Mr. A. D. Hall as chairman, Mr. G. Gordon as vice-chairman, and Mr. Walter P. Wright as secretary and treasurer being received and carried with acclamation. A list of vice-presidents was established. With a view to extending the sphere of the society, Mr. Wright proposed the institution of district committees, each with a secretary and correspondent having seats on the executive committee. After a little discussion on a suggestion that officials who were unable to attend the society's meetings should vote by proxy (subsequently withdrawn) the motion was carried unanimously.

In order to assist the executive committee in their choice of a place for holding next year's exhibition, a test of the feeling of the general meeting was taken. This was in favour of London, with possibly another exhibition in the provinces. Edinburgh and Doncaster were next in favour. The voting for the various places was, London 15, Edinburgh 6, and Doncaster 6.

A suggestion was made by Mr. W. Davie that something should be done to avert the disastrous effects of lawsuits on the Potato industry. This matter was fully discussed, and as a result it was decided to issue with the annual report a list of Potato experts, being trade growers and members of the society, whose services could be sought as arbitrators.

NATIONAL SWEET PEA SOCIETY.

THE annual general meeting of this society was held at the Hotel Windsor on Tuesday last, Mr. Whitpaine Nutting being in the chair. The report states, among other things, that the society finds itself in a stronger position in every respect than in any previous season. Increased membership is recorded. It is decided to hold the 1965 exhibition in the Royal Horticultural Hall, Vincent Square, on July 4. The Royal Horticultural Society will give £10 towards the fund, and will provide a supply of tickets to members. The financial condition of the society is better than ever. The balance in hand is £20 5s. 10d. This is less by £9 2s. than the balance last year at this time, but against this must be set the cost of vases, £9 17s. 6d., and staging, £7 15s., so really the society is better off by £5 10s. 7d. than it was a year ago. In 1963 the subscriptions amounted to £73 3s. 6d., and in 1964 to £92 10s. 6d.

Some discussion took place as to the maximum number of square feet of tabling to be allotted to non-competitive

exhibits at the annual show. It was resolved to suggest to the executive committee that this should be 100. Some dissatisfaction appears to have been caused because some exhibitors were allotted much more space than others.

The adoption of the report and financial statement was seconded by Mr. H. J. Jones, and carried without a dissentient.

Mr. Percy Waterer was elected president for the coming year, and it was resolved to send a letter to Mr. Henry Eckford thanking him for having accepted the presidency for 1964. Mr. N. N. Sherwood was re-elected treasurer, Mr. C. W. Bradmore was chosen chairman of the committee, and Mr. H. J. Wright re-elected honorary secretary. A vote of thanks was passed to Mr. Edward Sherwood for having performed the duties of treasurer during the absence of Mr. N. N. Sherwood. The election of members of committee, and votes of thanks to the officers and chairman closed the proceedings.

LIVERPOOL HORTICULTURAL ASSOCIATION.

A MEETING of members was held at the office on the 3rd inst., Mr. T. Foster presiding. The subject for consideration was "Up-to-date Manuring" by Mr. F. W. E. Shrivell, F.L.S., being the result of the trials at the experimental grounds at Tonbridge Green, Kent. The lecturer gave an interesting account of the work of Dr. Dyer and himself for the past ten years. At the conclusion of the lecture supplementary information was given in reply to questions, after which a hearty vote of thanks was accorded to the lecturer. A similar compliment to the chairman terminated the proceedings.

CROYDON IMPROVEMENT SOCIETY.

ON Tuesday, the 6th inst., this society heard from Mr. G. Dray, Sydenham, S.E., a well-delivered lecture on "The United Horticultural Benefit and Provident Society," a society formed some forty years ago to render assistance to gardeners, whether in private, nursery or market gardens, or in seed warehouses. In opening the subject he appealed to the younger members to help forward the cause. He urged them to join. The subject was fully gone into by the lecturer, and great interest was displayed in the lecturer's remarks. At the conclusion a very hearty vote of thanks was accorded Mr. Dray for so kindly bringing the matter forward.

ROYAL HORTICULTURAL SOCIETY.

THE meeting on Tuesday last was small but very interesting. The Colonial display formed the chief feature.

EXHIBITION OF COLONIAL FRUIT, &c.

The Royal Horticultural Hall was filled with exhibits of Colonial-grown fruits and of preserved and bottled fruits and jams on the 13th and 14th inst., at the first show of the kind ever held. The idea of holding a show of Colonial fruits has been before the council of the society for at least eighteen years, and now that its new exhibition hall has been opened the intention has become an accomplished fact, and the result has justified all expectations. It is, moreover, a happy augury for the future success of these shows when we recall the fact that the jubilee of our own Colonial Office as well as the centenary of the Royal Horticultural Society both occur this year. It is certainly regrettable that the Fellows and well-wishers of the society have not yet provided the full cost of the hall, which has been built as a permanent memorial of the centenary, and which will do so much in helping forward the future progress of horticulture in Great Britain and her Colonies. Till it is paid the Council will be hampered by a debt of £14,000, and the projected horticultural research station and the further development of the gardens must necessarily be kept in suspense. The invited guests at the private view last Monday included many well-known horticulturists, prominent Colonials now in England, the high officials of the Colonial, Indian, and Crown Agents' Offices, all the Agents-General of the Colonies, the principal representatives of the West India Committee, and others.

The schedule was divided into fifteen classes, ten of which were assigned to Colonial fresh fruit and vegetables, and the remaining five were allocated to preserved fruits, jams, &c. The first class was for a general collection of Colonial-grown fruit. There were also collections of Colonial-grown Apples (both cooking and eating) and Pears. Classes were also provided for Pine-apples, Bananas, Mangoes, Grapes, and other Colonial-grown fruits. There was also a class for Yams, Sweet Potatoes, and other Colonial vegetables. In the second division three open classes were provided for preserved and bottled fruits, including jams of home, Colonial, and foreign origin. Two classes were also allotted to British-grown fruits, bottled by the exhibitors entirely for their own household consumption. The judges appointed by the council included Messrs. G. F. Bunt, Michael Garcia, George Munro, and A. M. Walker, who are all commercially interested in Colonial fruits; Mr. A. E. Aspinall and Mr. Hedger Wallace, who are well acquainted with the Colonies and their fruits; Miss Bradley and Miss Crooke (of Studley Castle), and Messrs. G. Binyard, J. Hudson, W. Marshall, and A. Pearson, and the Rev. W. Wilks (secretary of the society). The Colonies officially represented were Canada, British Columbia, Nova Scotia, and the West Indies. Further interesting exhibits of Colonial fruits and products were entered by the Royal Mail Steam Packet Company, Messrs. J. Philip and Co., and the Dominica Agricultural Society.

The West Indian section, which had been organised by the West India committee, included official exhibits from Barbados and Dominica. The Royal Mail Steam Packet Company showed fruit carried by their steamers from Trinidad, Jamaica, and Barbados; Mr. Aston W. Gardner had an exhibit of Jamaica Oranges and Grape fruit; Messrs. L. Rose and Co., Limited, showed fresh Limes and Lime Juice; Messrs. James Philip and Co., displayed various West Indian

fruits, preserves, and pickles. Full particulars regarding the Islands, from the point of view of prospective settlers and intending visitors, may be obtained from the West India Committee, 15, Seething Lane, London, E.C. Gold medal.

The Barbados exhibit, sent by the Barbados Government through the Imperial Department of Agriculture, comprised Yams, Sweet Potatoes, and Barbados Bananas.

The Dominica exhibit was a representative display collected by the Dominica Agricultural Society at the Botanic Station, Dominica. Included were Lime Juice, Lime (Oil), Otto of Limes, Bitter Orange Oil, distilled Lime Oil, Shadlocks, Grape Fruit, Sweet Oranges and Limes, Sweet Oranges, Bitter Oranges, Citrons, Mexican Melons, Mangosteen, &c.

The Royal Mail Steam Packet Company's exhibit comprised fruits of remarkable variety, collected in Trinidad, Jamaica, and Barbados. Among them were Shadlocks, oranges, Bananas, Grape Fruits, Cashew Nuts, Gusvas, Ground Nuts, Golden Apples, Tree-crees, Gu-grus, Avocado Pears, Tangerines, Mandarins, Maine Apples, Granddills, Pater Nuts, &c. The vegetables included Papaws, Yams, Sweet Potatoes, Cassava, Chous-chous, Tannias, &c. Silver-gilt Knightian medal.

Messrs. Ashton W. Gardner and Co., through the Jamaica Agency, 28, St. Bride Street, London, E.C., sent Jamaica Naval Seedless Oranges and Jamaica Grape Fruit.

Messrs. James Philip and Co., 4, Fenchurch Buildings, London, E.C., exhibited all kinds of West Indian produce, pickles, preserves, &c., such as jams, Sweet Potatoes (pink or white), Limes, Shadlocks, Grape Fruits, preserved Guavas (jelly, marmalade, Dulce and cheese), Pineapple jam, Mangoes, &c. Silver-gilt Knightian medal.

Messrs. L. Rose and Co.'s exhibit comprised a general display of Limes from the Bath estate, together with bottles of Rose's Lime Juice, Lime Juice Cordial, and Limetta Ginger Cordial, the latter being a new winter drink recently introduced.

A very interesting collection of drawings of Jamaica fruits and models of Tasmanian fruits was lent from the Imperial Institute, by permission of the Director.

The Agent-General for British Columbia was awarded a gold medal for a splendid display of Apples from that Colony. It was a similar exhibit to that made a few weeks ago. The fruits were remarkable for their size and rich colouring.

The Agents-General for Nova Scotia and Canada respectively were awarded silver-gilt Knightian medals for exhibits of Apples. Those from Nova Scotia seemed to us to be fresher and generally better fruits, though both were excellent. The colour, more particularly than the size, of some was so rich as to make familiar sorts unrecognisable.

Messrs. Fowler, Lee and Co., Maidstone, were awarded a silver-gilt Knightian medal for a collection of bottled fruits.

The first prize for eighteen bottles of bottled British-grown fruit was won by Mrs. Banks, care of Mrs. Markham, Hasland Hall, Chesterfield; second, Mrs. E. Beckett, Aldenham; third, C. O. Walter, Esq., Ickleton House, Wantage.

For twelve bottles of bottled British-grown fruit, Mrs. W. H. Ploymann, Beddington Corner, Mitcham, was first; second, Mrs. H. V. Thompson, 19, Portman Square, W.; third, Mr. H. Bates, Robertshridge.

The exhibits of bottled fruits, jams, and jellies, from the Lady Warwick Hotel, Studley Castle, Warwickshire; Sir Walter Gilbey, Bart., Epsom, Essex (who also showed Lavender water made on his Essex estate), were given the silver-gilt Knightian medal. Messrs. E. and T. Pink, Staple Street, S.E., were awarded a silver Knightian medal for jams.

The Horticultural College, Swanley, showed bottled fruits and vegetables in variety, as well as jams and jellies, all made at the college. Mr. T. C. Shore, Snortheath, Farnham, Surrey, exhibited home-made jams. Messrs. Yeatman and Co., Limited, Denmark Street, S.E., showed jams, jellies, &c. Fresh bottled fruits were sent by the Bryden Horticultural Society, Monmouth.

ORCHID COMMITTEE.

Sir William Clayton, Bart., Marlow, Bucks, exhibited a group of Calanthe vestita Veitchii and also-oculata, that made a bright display. Silver Banksian medal.

Messrs. Stanley Ashton and Co., Southgate, N., showed Cattleya Loddigesii, C. L. var. striata, C. L. var. gigantea, C. L. var. atrovioacea, and C. L. var. alba. Lelia purpurata, var. unicolor and various Cypripediums were also included in the group. Vote of thanks.

Trichoplia suavis, shown by Messrs. Charlesworth and Co., Heaton, Bradford, made a pretty display. Some thirty plants, all in fine bloom, were shown, making a very attractive group. A good deal of variety in the lip markings was noticeable, some of them being very beautiful. Lelia-Cattleya Charlesworthii, with orange-red flowers, and various other hybrid Cattleyas were shown by Messrs. Charlesworth. Silver-gilt Flora medal.

NEW ORCHIDS.

Cypripedium × *Dom Carlos*.—This is the result of a cross between *C. Godefroyi* leucociliatum and *lawrenceanum*. It is intermediate in shape, the dorsal sepal being marked with dark crimson upon a light ground, tinged with richer crimson. The petals are spotted with deep crimson upon a light green ground, and the pouch is cream-coloured, streaked with crimson. From Norman C. Cookson, Esq. Award of merit.

Cypripedium tracyanum.—*C. aureum* and *leucanum* giganteum were the parents of this Orchid, which has a large dorsal sepal that curves at the top and narrows considerably at the base. It is green and brown, with a broad white margin; a very distinct form. From Mr. H. A. Tracy, Twickenham. Award of merit.

Cypripedium lambianum.—This is an attractive hybrid, with light green petals and sepals tinged with brown, while the dorsal sepal, which hangs over the flower so that the apex is in a direct line with the base of the somewhat protruding lip, is white except for a patch of green at the base. From E. Ashworth, Esq., Harefield Hall, Wilmslow. Award of merit.

THE GARDEN

No. 1727.—Vol. LXVI.

DECEMBER 24, 1904.

THOUGHTS ON CHRISTMAS DECORATION.

ONCE more Christmas is with us. Once more the forces of labour and commerce throughout the world are more or less relaxed, and the hurly-burly of life gives place to a spirit of rest, joy, and thankfulness. Christmas brings a welcome pause in the strife, a resting milestone on the road of life—milestones, alas! which seem to meet one at much shorter intervals than used to be the case. It is a time for the happy reunion of friends long separated. No labour is counted too great in our efforts at making homes and churches assume a bright and welcome presence. Many and various products are brought into requisition, but, after all, no source of supply can approach in usefulness and beauty that which the garden supplies. A pleasant change in the manner of carrying out this work has taken place of late years. Once it used to be the common practice to depute this work to others, who, if not artistically clever, often produced depressing effects by using too much material. Now this is all changed; the work, if not practically carried out by the members of the households and churches, is executed to their instruction and under their personal supervision, with the result that really pretty and artistic decorations are now the rule and not the exception.

It is our purpose here only to point out a few rules and principles to be observed in carrying out the work. The first thing of importance to settle, especially in the matter of church decoration, is to divide the work into sections, and to appoint a responsible head over each section with others to help. In this way a mild rivalry is established, generally ending in much better work being done all round. Another rule is never to overweight the decorations by using too much material. This is a common mistake, heavy decorations are always a failure and dispiriting. Brightness and distinctiveness are essential points. When you use any colour, whether red, white, yellow, or green, it must assert itself in the arrangement and not be spoilt by the mixing of the colours indiscriminately. For instance, if dealing with the pulpit the columns dividing the panels should be treated with one subject, namely, a flat, neat wreath, nearly the width of the column. This should be formed of a small leaved evergreen. Each column must have

only one colour, but the colour may be varied in each column. The mouldings above and below the pulpit should be treated similarly. Around the base of the pulpit and the stairs there should be groups of Palms and flowering plants in pots, chiefly white, the panels of the pulpit being reserved for the artist's choicest work and rarest flowers. We should like to suggest an artistic treatment of the altar and chancel, the lectern, font, windows, pillars, and gallery, but space forbids, and we hope enough has been said to excite interest in the work, and to indicate a few of the lines on which it should proceed. As regards home decoration this is of a simpler character, varying according to means and opportunities. It may range from elaborate floral work to that of the bunch of Mistletoe and Holly in the lowly cottage.

“THE GARDEN.”

IT has come to our knowledge that some uneasiness is felt and is freely expressed with regard to the promised issue of THE GARDEN at the price of One Penny. “Don't see how it can be done for the money” is the general wording of the feeling. Such a remark is quite to be expected, as well as the accompanying surmise that in some way or other the paper will be of less value.

It remains for those who own and conduct THE GARDEN to show the horticultural public how the value can be kept up although the price is reduced. The published prospectus has already stated that the tone and character of the paper will be absolutely maintained, while it is confidently expected that its utility will be increased.

THE GARDEN has made for itself a special place in horticultural journalism. It has, from the first, been the foremost exponent of beautiful gardening, and of the just appreciation and right use of the best flowers, shrubs, and trees, while the scientific side and details of practical working have had their due space. It is largely owing to its influence that the knowledge of the better and more intelligent ways of gardening, now so generally practised, or at least attempted, has been placed within the reach of those wishing to learn.

The paper then, having these sound and excellent traditions, it must be clear to all that no sensible management could possibly contemplate any change that could tend to lessen its influence or in any way lower its character. The intention is that its character shall be fully maintained, and its fine traditions

preserved, while its general usefulness will be increased by the lessened price, putting it within the reach of the whole horticultural public.

Letters of congratulation are being received daily from well-wishers of THE GARDEN, and the following have been selected as examples:

“May I be allowed as an old subscriber of your paper, and as one who has received great courtesy from its managers, to congratulate you on the forthcoming change in price of THE GARDEN, which I sincerely hope may double its number of subscribers within the first quarter. The paper has always been one if not the most interesting and useful gardening weeklies which has been published.—CHAS. WM. CROSBY, *Broome Hurst, Dorking.*”

“It is delightful to be able to get THE GARDEN now for a penny. I shall subscribe for two copies instead of one. I have always of late years given my gardener my copies bound, but parted with them rather regretfully. Now I shall have a double set of volumes. I shall tell all my friends, some of whom I know would have liked to take in THE GARDEN, only would not go to the former price.—M. SIMONDS, *Audleys Wood, Basingstoke.*”

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or bardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

CARNATION SIMPLICITY.

Mr. H. Elliott, Courtbushes Nursery, Hurstpierpoint, writes: “I am sending you a novel Christmas bouquet, consisting of a few blooms of my new single winter-flowering Carnation to be known as Elliott's Simplicity. I have been working for a good form of single Carnations for five or six years, and I believe I have in this succeeded in producing a good thing. It is not exactly a market sort, being too fragile to bear journeys by rail or post, and I have some doubts about this reaching you in good condition. As they are now before me the colour is a soft clear pink, the flowers 3 inches in diameter, perfectly regular, flat, with the edges, which are fringed,

slightly turned up or incurved, on very strong, erect stem, 2 feet to 3 feet high. The plant is very vigorous, and the blooms, which are slightly clove-scented, are freely produced during the whole winter. As the plant is so strong, it is very easily grown, treated in the same way as the ordinary winter-flowering tree sorts. The plants are grown in pots out of doors during summer and taken into the greenhouse in winter, or planted out in the open ground in April and potted up in August. For the decoration of rooms in vases, for the dinner-table, and many other purposes cut, or for the conservatory or greenhouse as plants, this variety will be acceptable."

[We think the variety sent a very good one. It is single, but the petals are broad, and the colour is very soft pink, while there is a delicate fragrance.—Ed.]

APPLES FROM BRITISH COLUMBIA.

At the direction of the Agent-General for British Columbia I am sending you a few specimens of Apples grown in that province of Canada. These formed part of an exhibit made by the Government of British Columbia, which was awarded the Royal Horticultural Society's gold medal at their show of Colonial fruit held on the 12th, 13th, and 14th inst.

It might be pointed out that this is the second time during the present year which this distinction has been conferred on the Province.—J. A. TURNER, Secretary.

[The Apples sent were very richly coloured, and their condition gave evidence that they had been most carefully packed for their journey of some 6,000 miles by land and sea. The flavour of most was excellent.—Ed.]

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 2, 1905.—Meeting of the Mansfield Horticultural Society.

January 3.—Royal Horticultural Society's meeting; meetings of the Redhill, Reigate and District, and the Sevenoaks Gardening Societies.

January 11.—Sheffield Chrysanthemum Society's meeting.

January 14.—Annual Dinner of the French Horticultural Society of London at the Café Royal, M. Philippe de Vilmorin in the chair.

January 17.—Meetings of Reigate and Sevenoaks Gardening Societies.

January 19.—Annual meeting and Election of Pensioners of the Gardeners' Royal Benevolent Institution.

January 24.—Royal Horticultural Society's meeting.

New Fellows of the Linnæan Society.—We are very pleased to hear that Miss Willmott has been elected an Honorary Fellow of the Linnæan Society, the first lady we believe to be enrolled a member of this institution. All good garden lovers will rejoice that one who has done so much to promote a love for flowers and horticulture generally has received so marked a distinction. Mr. Tatcher, assistant superintendent of the Hong Kong Botanic Gardens, was also elected a Fellow. His unobtrusive botanical work well merits the honour.

Fruit for sick children.—The Hospital for Sick Children, Great Ormond Street, has received a handsome gift of fruit from the Dominica Agricultural Society. This fruit was offered to the King for his acceptance for the London Hospitals, and at his suggestion it was sent to the above hospital. Amongst the fruit were some eleven crates of Bananas, many boxes of Limes, Navel Oranges, Grape Fruit, Citrons, and Apples. The last-named were grown by Lord Aberdeen on his ranch at Vernon, British Columbia, and exhibited by the Agent-General of British Columbia at the Royal Horticultural show which closed on the 14th inst.

Royal Botanic Society of London. Messrs. Dobbie and Co., Rothesay, have been awarded a gold medal for a collection of early-flowering Chrysanthemums grown for trial in the society's gardens at Regent's Park.

Solanum Wendlandii in Portugal. In the last issued Bulletin of the National Horticultural Society of Portugal there is an illustration of a splendid specimen of *Solanum Wendlandii*, from a photograph of a plant that appears to be quite 8 feet high. It is in full flower out of doors in a school garden.

The precocious *Leucojum aestivum*.—It is interesting to read Mr. S. W. Fitzherbert's report of the still earlier flowering of his precocious *Leucojum aestivum*, and I may be allowed to supplement his interesting note by saying that Mr. Fitzherbert's precocious form, which he kindly sent me at the time I had the pleasure of giving him a few bulbs of mine, is not the earliest with me, and practically flowers at the same time as several other clumps of *L. aestivum* received from various sources. On the other hand, my earliest form is not any earlier than others with Mr. Fitzherbert, so that one has no idea of what is the cause of this erratic conduct. Perhaps some of the many readers of THE GARDEN who grow the summer Snowflake will tell us their experience of the plants in their gardens? I have some six or seven different lots, including one collected on the Bithynian Olympus.—S. ARNOTT, *Carsethorn, by Dumfriess, Scotland.*

The flowering of Snowdrops.—The first Snowdrop of the season opened here on December 15, and is one of a lot of *Galanthus Elwesii* received from Asia Minor in 1902. It has anticipated such Snowdrops as *G. Rachelæ*, *G. Elsæ*, and even *G. octobrensis*. I am aware that there are some places in Scotland where Snowdrops come earlier than this, but there are few others where such "autumnal" Snowdrops as those named are cultivated, and the point is worth noting for comparison. My experience is that the flowering of Snowdrops depends much upon the rainfall of the preceding autumn. This one the rainfall was later and not so heavy, and Snowdrops are later than in some years. One finds, however, that the "autumnal" Snowdrops, such as *octobrensis*, *Elsæ*, *Rachelæ*, and others, have a tendency to draw nearer to the flowering period of the ordinary Snowdrops as they become settled in one's garden, and it looks as if it would not be long before they adopted the normal blooming-time of the common Snowdrop. Some of my correspondents have experienced the same thing, but some further information from others would be welcome and useful.—S. ARNOTT, *Carsethorn, by Dumfriess, Scotland.*

Obituary—Mr. Robert Bryson.—There died on Thursday, the 15th inst., Mr. Robert Bryson, High Street, Newburgh, Fife, who was for a number of years a very successful exhibitor at many of the local flower shows, and who was a gardener of great ability. For many years he was in the employment of Mr. William Guild of Parkhill as head gardener, and did very creditable work in that capacity. Mr. Bryson was eighty-eight years of age.

Violet Comte de Brazza.—I notice on page 418 in THE GARDEN of the 17th inst. that "F. H. C." mentions his inability to grow and flower the above Violet well. He says it is such a bad grower and shy flowerer. With me it grows very well indeed, and also flowers well; of course, not so profusely as the blue sorts, such as *Marie Louise*, *Lady Hume Campbell*, and others, but still it flowers well enough to give entire satisfaction, and I think it is the best of the double whites. No doubt the success of growing Violets much depends upon attending to trifles which some growers regard as of small importance. A few details on cultivation may be worthy of a note. In April I always split my Violets to one crown, then plant them on a well-manured and deeply-dug rich border, partially shaded, facing east, keeping the runners cut off during summer, and watering overhead should they require it. Owing to partial shade the plants will be found to grow luxuriantly when they have got hold of the soil.

In lifting the plants again in the early part of September to place in their winter quarters, retain as much soil on the plants as possible. (I never reduce the ball when lifting.) Take care that the soil for planting in is not very rich. This I find of the greatest importance to get an abundance of flower. The planting in frames in too rich soil is no doubt the cause of failure with Violets. Give plenty of air, not too much water at the roots, and remove any damp leaves that may occur. Avoid manure in any form. As the strength of the crowns are built up in summer, too rich soil at this period only produces leaf growth in excess. If "F. H. C." gives *Comte de Brazza* one more trial under the above conditions I think he will meet with success. I may add that I have been picking a splendid lot of Violets since September, and at the present time I have a good supply and of good size, grown precisely under the above treatment, and I have never had Violets fail with me under such conditions. I never use any covering whatever for Violets in frames other than the lights, and find it is quite unnecessary to do so.—J. HIGGINS, *Rdg Gardens, Cornwall.*

Rondeletia speciosa major.—Though at one time very popular for growing into specimen plants this *Rondeletia* is not often met with nowadays, yet it is not only pretty when in flower, but the neat bright rounded clusters are very useful in a cut state for buttonholes and for similar purposes. When needed for cutting from a very good plan is to train up a plant against the back wall of a stove if not too much shaded, or in some similar position, as in this way a specimen can, apart from its usual season of blooming, be depended upon for a few flowers almost throughout the year. For treating in this way it will do better in a prepared border than in pots, but the matter must be so arranged that the plant does not get unlimited root room. Cuttings are not at all difficult to root, while its cultural requirements are in no way exacting. This *Rondeletia*, which is a native of Mexico, was introduced into this country in 1836. Though the name is thoroughly fixed in gardens, *R. speciosa* is in the "Kew Hand List" referred to as *R. odorata*. While alluded to above as a stove plant, such treatment is by no means necessary to its well doing, as it is equally at home in a structure where an intermediate temperature is maintained, which just suits, among other plants, the different *Aphelandras*, most of the *Eranthemums*, *Ruellias*, and numerous other beautiful flowering subjects. The Mexican house at Kew well serves to show the great number of distinct plants that can be grown under these conditions.—H. P.

Destroying wild flowers.—The Devonshire County Council decided recently to stop the wholesale stripping of wayside banks and hedges and other public places in order to supply wild plants and flowers for Covent Garden Market. Tons of Ferns, Primroses, Daffodils, and other plants are gathered and despatched to London in spring and summer, and the County Council has now passed a bye-law to prohibit this destruction. Persons offending in future will be liable to a penalty of £5 or a month's imprisonment. Special exception is made in the case of persons gathering flowers for pleasure or for the purpose of botanical study.

The most useful Chrysanthemums. It is generally admitted that if you want to find out the best (or, at any rate, the most popular, and therefore one may, I think, safely say the most useful) varieties of any flower, fruit, or vegetable, the wisest plan is to learn from the man who grows for market. Those who are interested in Chrysanthemums may be glad to know which varieties, according to the judgment of Covent Garden experts, are the best for market culture. The National Chrysanthemum Society held an exhibition in London last week of market-grown flowers. There was no doubt about their genuineness, for many leading trade growers were among the exhibitors, and it was stated that after the show all the flowers that were good enough would be taken to Covent Garden Market for sale there the next morning. The most popular variety in the show, to form an opinion from the number of times it was included in the exhibits, was *Tuxedo*. It

belongs to that class whose colouring is usually designated as bronzy yellow, and perhaps that is as near as one can get in a general way, for there is such a charming blend of shades of varying strength among them that is almost impossible to describe. In attempting to give the colour of Tuxedo, I should add that the bronzy yellow is largely tinged with rose, resulting in a very beautiful tint. In the classes for the best market varieties of certain colours Tuxedo won the first and also the second prize as the best bronze-coloured Chrysanthemum. The best white the judges considered to be Mlle. Therese Pankoucke. Framfield Pink, synonymous with Mme. Felix Perriu, gained the first prize among the pinks. The judges thought Violet Lady Beaumont the finest crimson, while one called Reiman was decided to be the best yellow. It would hardly seem necessary to add any further recommendation to the decision of the judges, but I might say that these flowers appear to possess the qualification that is essential to all cut flowers for home decoration, that is, the petals are of good substance and will last well. The colours, too, are clear and decided, which is also an advantage.—Y. Z.

The Maidenhair Tree.—There have recently been several notes in THE GARDEN about this most beautiful tree, and one is led to ask the question whether it is increasing in English gardens. One so rarely sees any young trees planted that there is, I think, some justification for enquiring whether planters are taking steps to ensure its preservation; for if young trees are not planted sooner or later it will disappear from cultivation. It is strange that it has not become a popular tree; perhaps its slow growth and, I believe, difficult propagation have a good deal to do with this. I know of no deciduous tree that has a more graceful appearance when in full leaf, each Maidenhair Fern-like leaf pointing towards the ground in a large specimen conveys the impression almost of a weeping tree. It is so absolutely distinct in appearance from all our other deciduous garden trees, and quite unique in its rich green leafy covering that seems to clothe the branches in so graceful and attractive a manner. Just as one might compare the clothes of a prince with those of a peasant, so it always strikes me you might truthfully and to its advantage compare the green, gracefully hanging, leafy cloak of the Maidenhair Tree with the louse, badly-fitting foliage of any of its commoner neighbours. There is a subtle charm, a distinct fascination, a dignity about this tree that can trace its descent to far remote geological ages. As the Beech is, perhaps, the finest of our British trees, because of the combination of strength and gracefulness in its giant limbs and slender twigs, so, to my mind, the Maidenhair Tree is even more attractive, because these two qualities are more effectively associated. In its autumn colouring it, too, has a beauty all its own; perhaps it is at its very best when some of the leaves have fallen, when the shape of the individual leaf can be seen, and the pale yellow foliage shows in contrast against the dark branches. In winter its distinctiveness is still preserved in the characteristic divided limbs, erect branches, and horizontal shoots. Can anyone tell me the best stock upon which to graft this tree?—Y. Z.

New Potatoes for Christmas.—Two interesting exhibitions of these winter delicacies have been recently shown at the Royal Horticultural Society's meetings at the new hall, Vincent Square. The first showed the result of saving the old seed tubers of last spring, storing them in cool positions, and rubbing off the growths as they appear during the summer, in order to prevent the tuber from softening and exhausting itself in the production of shoots. The tubers exhibited were told were placed on the soil (not planted or covered with soil) in an ordinary garden frame on the 17th October last, and the tubers so placed and the crop attached in the shape of numerous young Potatoes of all sizes, from the size of Peas to pigeons' eggs, were shown on the 29th ult. We think had they been allowed a longer time to develop they would have been larger, and therefore the crop more valuable, as there was a large percentage of small useless ones. It does not make

any appreciable difference whether the sets are late, mid-season, or early sorts, but what is important evidently is that the variety must be one that produces a cluster of Potatoes around the main stem, such as was the case in the best sample shown in the exhibit in question; the variety was Windsor Castle. With this collection was a sample of the young Potatoes in a cooked state, and although these were cold the flavour and quality were excellent. This is not a new method of producing new Potatoes in winter, I used to practise the same system thirty or more years ago. But instead of putting the sets in a garden frame, as in this instance, we used to place them resting on some leaf-soil in shallow boxes, putting the boxes containing them on shelves in any convenient place in the fruit or seed rooms. There it was comparatively dark, with a temperature of from 50° to 55°. The singular and almost uncanny part of the method is that no semblance of leaf-growth takes place. At the last exhibition of the Royal Horticultural Society, on the 13th inst., another dish of new Potatoes of excellent quality was shown. These were grown under more normal conditions, namely, from sets of early Potatoes grown in frames and taken up early last spring. Those wishing to possess new Potatoes at Christmas, 1905, may easily have their wishes gratified by planting an approved early sort in pots or frames (possessing the minimum of heat required, from 50° to 55°) next January. These should be ready to take up at the end of April or early in May. It is from these early Potatoes that sets for the Christmas crop must be saved.—O. T. E.

French Horticultural Society of London.—The date of the annual banquet of the above society has been fixed for January 14, and M. Philippe de Vilmorin will occupy the chair on that occasion. The secretary, Mr. G. Schneider, is most anxious to make this a record banquet, and to show the chairman, who comes purposely from Paris, that the society is much appreciated, and has many friends and supporters here. The dinner will take place at the Café Royal, 68, Regent Street.

Gardeners' Royal Benevolent Institution.—The Duke of Westminster will preside at the sixty-sixth anniversary festival dinner of the Gardeners' Royal Benevolent Institution, on June 16 next, at the Whitehall Rooms, Hotel Metropole.

Mr. A. F. Dutton.—Visitors to the Shrewsbury Flower Show in August last will remember a fire which occurred, but was extinguished at a critical moment by Mr. A. F. Dutton, of the Nurseries, Bexley Heath, Kent. The Shropshire Horticultural Society have recently had a meeting, and in recognising the service rendered have presented Mr. Dutton with a handsome silver waiter, inscribed with his name and address.

Gardening for Dundee school children.—Great as has been the success attending the movement to encourage a taste for flowers among the school children in Dundee by means of a bulb competition, the movement has in the past autumn attained dimensions never expected by its most sanguine promoters. In autumn upwards of 38,000 bulbs were distributed among the children, at a cost of about £64, and at Dudhope Park, where the children who apply for it are given a supply of leaf-mould by Mr. Montgomery, the superintendent, upwards of 2,000 have been supplied. Mrs. Carlaw Martin, who originated the movement, has reason to be highly gratified by the success of her efforts. A new development is also under consideration by a small committee of the School Board of Dundee. This originated in a letter from Mr. James Malloch, suggesting that a small garden should be laid out in front of Blackness School. There are, of course, several important questions involved, but the proposal is certain to have sympathetic consideration from the authorities.

Royal Caledonian Horticultural Society.—The council of this society and the representative committee to co-operate with the council in connexion with the 1905 international show, met at 5, St. Andrew Square, Edinburgh, on Wednesday, the 14th inst., to revise and adjust the

schedule of prizes for the international show. As adjusted, the schedule includes handsome prizes for fruit, plants, cut flowers, vegetables, and an experimental section, besides a competitive plan for under gardeners, the total prizes amounting to over £1,400. It is expected that the schedule will be issued early in 1905. Donations to the amount of over £600 have been intimated, but in order that the exhibition may be really worthy of the occasion the council hope that further donations may yet be received.

George Ellwanger, who celebrated his eighty-eighth birthday recently, is one of the most celebrated American horticulturists. Many friends called to offer their congratulations, and also to present Mr. Ellwanger with a silver coffee service as a token of their esteem and regard. In the address presented we read: "As a boy you learned your profession of a nurseryman with all the thoroughness of a German, and in manhood you practised that profession with all the energy of an American. Engaged in a business where it is easy to deceive, and where deceit could not readily be discovered, you have made your name the world over a synonym for absolute integrity. Your life as a citizen has been one we may all emulate. You are held in high esteem by all who know you, and honoured by those to whom you are simply a name."

Dicentra spectabilis.—This is a well-known beautiful hardy flowering plant, introduced into Britain from Northern China by the Royal Horticultural Society, through the agency of their great traveller Robert Fortune, in 1846. The *Dicentra* is only a common hardy plant, costing now but a few pence to buy, but for beauty and usefulness, either in the cottage or palace garden, few of the many valuable importations of the society excel this plant in charm and elegance of foliage and flower. In the rush of late years for novelties so freely offered to the garden-loving public, I am afraid the value of this beautiful plant has been somewhat lost sight of. Years ago one used frequently to come across large bushes 3 feet and 4 feet through and as high, loaded with its two-winged lyre-shaped pendent flowers. These are a beautiful rosy pink, and with the pale green foliage present a rare picture of plant beauty. This is a plant that does not like being disturbed or replanted too frequently, therefore those intending to plant should select a sunny spot in which it may have room to grow and luxuriate for many years. It will not succeed in wet, heavy soil, and where these conditions exist warmer and lighter soil must be substituted. When forced for the decoration of the conservatory and arranged in association with bulbs and Azaleas, &c., in flower in spring, its value is well known.—O. T. E.

Reinwardtias.—These old winter-flowering greenhouse plants are worthy of more general cultivation than they receive. They are somewhat shrubby in character, natives of the mountains of the East Indies. Cuttings root readily in a propagating frame in spring. They should be pinched several times during the summer to induce compact growth. If larger plants are required old plants may be cut back and grown on for several years. A temperature of 50° to 55° is necessary during the flowering season. They are very subject to red spider, so require frequent syringing. *R. trigyna* (orange yellow) and *R. tetragyna* (primrose yellow) are now flowering freely in the greenhouse at Kew.—A. O.

Luculia gratissima.—Planted out in a bed a bush of this plant some 8 feet in height is carrying over 100 trusses of flower. The very sweet scented flowers are of a delicate rose or pale pink colour. Grown as a pot plant it is not very successful. Planted out in a bed or border it flowers freely annually. As a compost, fibrous loam, peat, and coarse sand are suitable. It is a native of the Himalayas.—A. OSBORN, Kew.

Colour in the garden.—I notice that on page 334 "T. A." Cirencester, remarks upon "the extraordinary colouring of the autumn foliage." I do not know if this bright colouring has been noticeable in the majority of counties this year, but certainly it has not been observable in the south-west, where the autumnal tints have been poorer

than for twenty years. I have been much disappointed in this, as on account of our glorious summer I had been looking forward to exceptional brilliance at the time of the turn of the leaf. Several friends to whom I have spoken on the subject agreed that the colouring was unusually poor. The Wild Cherries on the banks of the Dart quite lacked their glowing crimson-purple, the burnished copper of the Beeches was far duller than in former and wetter years, and even the pale gold of the Elms was less bright than usual. In southern Cornwall I remarked the same lack of colour. — S. W. FITZGERBERT.

THE FLOWER GARDEN.

ANTIRRHINUM GLUTINOSUM.

THIS pretty Spanish plant deserves more general use in wall gardening in our southern counties. It would scarcely be hardy in the north and the midlands, but south of London does well in wall joints, as the picture shows. It is easily grown from seed. The only care the seedlings need is to ensure that the crown of the plant is well within the opening between the stones—anything from 2 inches to 3 inches—to ensure good protection from cold and wet in winter. The foliage is grey and downy, the flowers warm white, with a distinct yellow blotch on the lip. It grows spontaneously on the walls of the Alhambra in Granada. G. J.

PENTSTEMON BARBATUS.

IN his note on this Chelone "S. W. F." says *P. b. Torreyi* is more vigorous than the type. This I agree with, but consider the type to be a much better flower. The intensity of colour is so much to be preferred, being really a deep crimson, whereas in *P. b. Torreyi* it is a washed-out red, quite pale and unattractive. In our heavy soil neither of the two forms winter well in the open; the main portion of the plants are crippled. In consequence of this the growth in spring is weakly, and the flower-spikes correspondingly so. In October I break up the old roots, plant the most vigorous of them in boxes, wintering these in a cold frame, putting them out again in early April, and from these I get flower-spikes 4 feet long. E. M.

THE CUSHION (ONCOCYCLUS) IRISES.

THOSE who have endeavoured to grow the Cushion Irises, and particularly those of your readers who believe that the drying-off method out of ground is wrong, the idea of planting them at the present time may appear foolish. But it may not be so wrong as one might suppose. I have before stated in *THE GARDEN* that I regard the trying conditions of an English winter as most unfavourable for the growth of these plants. Why? Because the imported plants coming to us year by year from their native haunts and other sources have already endured probably a protracted term out of ground, and have doubtless received a greater share of that complete rest which is rightly, I consider, regarded as essential to their welfare. The grower, desirous of conforming to the dictates of catalogued instructions, hastens to plant them forthwith. And, in their turn, the plants, coming into contact with the warm and moisture-laden soil and environment of an English garden in the early autumn, are naturally quickly responsive, and in a few days root fibres may be emitted from the rhizome and shoots appear above ground in a very short time. But is not this all wrong for a group of plants that we know and believe prefer a warmth while growing to which we in England are strangers? Were it possible that the plants make root only, and that no top growth were visible before the warming influence of spring, then to proceed unchecked to the maturing stage, it is more than likely a better flowering would ensue and a finer development in the plant for its future work. But this is not possible if we cling tightly to orthodox methods.

Impatient by reason of a long-continued season of out-of-ground dryness, which in itself is infinitely more complete than any other form of enforced rest, the plants, earlier to ripen in their native conditions, or probably early collected in the wild state as a matter of convenience to collectors, naturally spring quickly into activity, only to find the environment uncongenial and unsuited to general progress. In this stage of their existence the choice, freshly formed shoots of these Irises are rarely missed by slugs, and, rather than wait for these pests to sample a few of the strongest breaks, I give an occasional dusting of freshly collected soot, and take the further precautionary step of forming a ridge or belt around the bed or the plot of ground. But what may be equally good, or even better in the end, and more especially on clay soils, is the adoption of a method of deferred planting. This need not be of the whole stock. It were better it should be an experiment of a part for comparison and reference. Those who know anything at all about an Iris are aware of the remarkable vitality of the rhizomatous species in general.

In adopting this deferred method of planting it is suggested that it be for the express purpose of endeavouring to keep the top growth below ground until the worst of our wintry weather is over. Meanwhile it is not suggested that the rhizomes shall be exposed to external conditions.

Some years ago, with much the same belief in this particular as I hold to-day, all my home-grown stock of *I. susiana* was lifted or shaken out of pots about the middle or end of July, and when dried sufficiently were placed in quite dry silver sand in large pots, which were transferred to a dry and very airy shelf in a potting-shed, the roof of which was of thickened and obscure glass.

In this way the plants kept perfectly, and planting was done very late in November or early in December. By these means growth was retarded, and the only appreciable difference was a somewhat reduced stature at flowering-time. The above circumstance was recalled the other day when planting some dry roots, and I have marked them for comparison with others planted much earlier. Already *Iris susiana* is well above ground. Some established plants, indeed, not lifted at all this season, have hardly relinquished the green leaf, though in a sunny and warm spot. On the other hand, some of the new *Onco-Regelia* kinds from M. Tubergen, planted in early October, very quickly made a start, two of the kinds in a small set displaying a welcome vigour. One plant, indeed, has already four strong shoots through the soil, and another just half this number, while several others are still below the surface.

As these new kinds are of varied parentage, the slowness or activity to start into growth when planted may be explained in this way, and I am noting this for future reference. I

believe I am right in stating that the whole of these Irises, if not, indeed, the Cushion Irises also, are subjected by M. Tubergen in Holland to annual lifting. The plants I received gave one infinite pleasure by reason of the strong and clean, vigorous, dormant crown and side-buds. Seeing how great a success has been secured in Holland with these fascinating novelties, the cultivator at home should have nothing to fear for his own success if the plants are well cared for.

Hampton Hill.

E. H. JENKINS.

THE PENTSTEMONS.

THE illustrated note you published on page 348 of *Pentstemon Bridgesii* served to remind me of the beautiful garden plants in this genus, plants that one rarely, if ever, sees nowadays used in the border, a circumstance probably due to the increasing popularity of the more showy hybrids of *P. Cobet*, *P. Hartwegii*, and *P. gentianoides*, and to a supposition (it is nothing more) that these species are of weakly growth, tender, naturally short-lived, and weedy. There are, in fact, many showy and very hardy plants among them, the worst forms of which are not to be discarded, whilst the best of them excel in their free growth, the rich and refined colourings of the invariably tubular flowers, in which rose, salmon, amethyst, azure, lilac, violet, scarlet, carmine, and white are individually represented in their best shades, and often in splendid contrast to leafage that resembles *Crassula* and *Echeveria* in shape and glaucous tint. They range in height from the slender *P. humilis*,

ANTIRRHINUM GLUTINOSUM ON ROCK WALL.

as charming a plant as ever graced a rockery, and of the brightest blue colouring, to the vigorous *P. Palmeri*, *P. ovatus*, *P. barbatus*, and *P. Scouleri*, which are the least vivid in their colouring. Their duration is generally perennial. A few only are undoubtedly biennial, and many of these, if grown well, reach the third and fourth year in a vigorous state, especially in naturally warm and free soils. They will often, in common with many perennials, flower themselves to death, but, as they bloom and seed freely and are not difficult to rear, there is no difficulty in keeping a collection together. Generally it is better to plant in spring. Several of the best make long simple roots that go down deeply, and if these are injured in transplanting in autumn, and the collar or rhizome exposed, the plants quickly succumb to frost, wind, and wet.

With the single exception of the florists' forms, which get more tender as the plants improve in size of flower and substance of petal, there is no necessity to "winter" *Pentstemons* under glass. Cuttings of a few doubtfully hardy kinds may be taken in the earliest autumn, but the plants themselves winter best in the open if undisturbed. Where *Montbretias* struggle to live throughout winter, and particularly in winter-wet districts, it may be necessary to protect *Pentstemons*, not otherwise.

There are about forty species known to cultivation, and I believe many more are grown in America than we know of here. The best border plants are those that most resemble *P. barbatus* (the *Chelone* of gardens), and of these I consider *P. acuminatus*, whose flowers are reddish purple, and *P. secundiflorus*, *Fuchsia*-like in its elegant habit, with arching spikes of deep blue flowers, good indeed. Forms of *P. barbatus*, both of hybrid origin and seminal sports, give us scarlet, carmine, rose, palest salmon, and pink flowers in many pretty and useful shades. *P. spectabilis* is a good pink, in graceful tall panicles. Blue in several pretty shades is the colour of *P. speciosus*, and both flowers and panicles are very large. *P. Palmeri* reminds one of the florists' *Pentstemons* in its large, rosy, distended flowers, on spikes 3 feet high.

P. Bridgesii, a bright red, and *P. Richardsoni*, an elegant bush, with *Alonsoa*-like leafage and dainty panicles of bright purple flowers, long tubed and exceedingly graceful, and *P. heterophyllus*, a kindred plant, whose flowers are a beautiful sky blue and freely borne, are a beautiful group.

P. Halli is a gem for the rock garden, forming a carpet of blue-purple flowers, and *P. glaber*, in its many shades of lilac, pale blue, and purple to deepest violet, the flowers in dense heads on nearly prostrate stems, which become erect if the plants are crowded, is well known.

P. cœruleus, a beautiful blue and exceedingly compact and free, and *P. azureus*, a similar plant with pale violet or azure white-tinted flowers in branched tufts 1 foot high, are among the best.

P. humilis has the *Gloxinia*-like flowers of the florists' *Pentstemon*, and the neatest habit and the brightest blue of all *Pentstemons*. It is naturally short-lived.

Strong-growing species which have flowers less showy than most are *P. digitalis*, a rather coarse plant, with stout spikes of white distended flowers; *P. ovatus*, undoubtedly a biennial, with broad clasping leaves and sturdy spikes of blue blossoms in great quantity fully 2 feet to 3 feet high; *P. mackayanus*, a sturdy plant with hairy leafage and pale purple flowers, of which selected forms only are good.

P. Menziesii and its forms are better known. Here again selections are necessary. The general colouring includes undesirable traces of slaty purple.

Finally, the glaucous-leaved *P. murrayanus* and *P. Wrightii* are exquisite plants. *P. Wrightii* in particular should prove of service in bedding for its leaf-colouring alone. The youngest leaves have a warm ruddy bronze tint, the older ones are almost as glaucous as the *Auricula*, whilst the flowers of bright carmine may be likened to those of *Bouvardias*. There is a wealth of good plants among them, and material still for the florist to use in the raising of new races.

(A. B. MALLETT.)

DOUBLE DAISIES.

Few small plants are equal to the Double Daisy for winter and spring flowering. Plants raised from seed sown in May or June begin flowering in early autumn. If in a fairly sheltered position or the winter is not too severe, they will continue to do so for seven or eight months. A very large percentage of the seedlings come double and true to colour. Division of the roots at the end of May or beginning of June is also practised, but, speaking generally, these do not flower so early in autumn as seedlings. One of the best double white varieties is *Snowball*. Four small beds of this variety in front of the Palm house at Kew have been flowering since planting, after the removal of the summer bedding. Being in flower when planted there, it was an easy matter to remove the one or two plants which had half-double flowers. A good pink variety is *Longfellow*. Firefly is useful as a scarlet, but shows a yellow centre, to which some growers would object.

A. OSBORN.

IN A SMALL WAY.

SIX whole weeks has the Oblong Eden lain in solitude and daily growing untidiness, while its Adam and Eve have been journeying by the new Elder Dempster route over the 4,000 and odd miles of ocean between it and the West Indies. It has been contrasted with Jamaica Gardens, and in spite of all the advantages of a whole year of June, tropical sunshine, warm tropical rain, and fertile soil, has come out nobly in altitude of scale. To be sure, the Jamaica Gardens will be richest in blossom just when the Oblong lies most deeply sleeping, and it may be that if we saw them then we should change our minds; but if we take even such a little amateur's plot as this is, and place it side by side with such gardens as—in July and August—may be seen in the lovely tropic islands under consideration, the superiority it owns in summer beauty will be at once apparent. In the first place, although we saw gardens—I am speaking of the general run, not of such rare individual and cherished belongings as that one of which we read in THE GARDEN'S pages—which had had care bestowed on them, they were greatly in the minority. About Kingston, where they come under the heading "suburban," they could in no way compare with the trim and tasteful parterres, not original to be sure, but blazing with colour and exquisitely tidy, which are common in the more countrified London suburbs—Putney for instance. Most of them looked as if they were left to themselves, and in only a very small proportion was there any attempt at making beds and so on, while a great many people tried the most of the splendid indigenous plants that a little cultivation would have rendered dreams of beauty.

The Roses we saw in these gardens were all of the garden sorts, such as the old-fashioned pink or white Cluster Roses, *Chinas*, or *Teas*, and the blossoms were small and the growth straggling. The grass, which is not at all like our English turf, does not equal it for lawns, being much more thin and open in growth. In almost every garden, cared for or not, there were great bushes of *Hibiscus*, either flaming crimson-red, orange-red, or of a pinkish cast as to the large showy blossoms. This is Nature's planting, and so are, I suppose, the glorious *Acacias*—called the *Flamboyant*—one sees in and around Kingston, laden with massed scarlet flowers, gleaming like fire in the sunshine. These trees—they are large ones, too—are magnificent in the summer, but I believe they are very ugly later on when the beautiful bloom has given way to quantities of squalid-looking

dingy brown seed-pods. At Mandeville, which with Kingston and Port Antonio at the north form a good representative trio of places for allusion, the earth is deep red, staining everything, and here the *Hibiscus* was in full glory.

The negroes do not seem to have the slightest idea of flower gardening, and in no single case did I see the smallest sign of interest on their part in any denizens for their plots but those which, like the *Banana*, *Yams*, or *Coffee-bushes*, come under the head of strict utility. The *Yams*, by the way, have to be grown like *Hops*, on poles, for if they are allowed to trail the ground no tubers would be produced. The *Crotons* form one of the chief attractions of the gardens both at Mandeville and Port Antonio, while at the former place *Dahlias* seem to be a good deal fancied. I only saw *Pompons*, but they did very well, and the flowers were as good as they were at home—perhaps better, although about a month earlier in coming. The *Crotons* were big bushes of the most splendidly varied hues, and some had three sorts of leaves, green and yellow, green and red, and all red, on one bush. They were being clipped in the hotel garden just as *Laurels* are at home. The flowers at the wayside, though they disappointed us, were a good deal more varied than those in the gardens. The "Spanish Needle" is the most common wild flower in the red earth, and has a blossom not unlike *Sparmannia*. Then there were quantities of *Thunbergias*, nearly all orange with black eyes, one white.

There were *Ipomœas* of one or two sorts, the commonest a medium-sized pink-purple, very pretty and showy, and at Port Antonio, where the soil is not red, but seems chalky, a curious flower with a *Thistle*-like habit but not prickly, whose blooms were like just a few plain primrose, uneyed, and I saw a long tubed slender *Stephanotis* blossom, and smelt sweetly, was extremely frequent. An Evening Primrose, neat and compact, grew freely by the roadside close to the sea, and the brackish marsh at its margin, which broke into *Mango swamps*—I have never seen anything much more desolate-looking than a *Mangrove* swamp scuttling with crabs—at intervals. There were *Oyster plants*, so called for no conceivable reason, which are like small *Aloes*, with deep red backs and the silver-green pointed leaves, and beautiful *Adiantums* of different kinds all over the banks edging the road which leaves the sea to go up into the hills. The *Bougainvillea* was good in a few Kingston gardens; so were *Allamandas*, and a *Brugmansia* in the hotel garden at Mandeville was about 12 feet high and as much round, covered with its splendid trumpets. We missed the *Orchids*, as they flower in January onwards, but it was curious to see them, with the handsome *Pine-apple* growing all over the trunks of roadside trees. A pretty little grass with red bracts like a tiny *Poinsettia* was interesting. There was nothing to bring home to the Oblong, as all the flowers, plants and weeds alike, are what one sees in warm greenhouses here—or would be so if imported. On the ship coming back there were a few *Orchids*, the property of passengers, which were mostly accommodated in the wheel-house, but they did not enter into our horizon, limited (sadly) to hardy things once home is reached.

The Hope Gardens, within an easy electric car ride from Kingston, are very interesting, but chiefly devoted to shrubs and trees. The Government keeps up several gardens in Jamaica, but they are, I should imagine, by no means heavily subsidised. The director, Mr. Fawcett, was most obliging in giving me leave to photograph (a permission

most unluckily stultified by my indulging in the mild fever which generally attacks the un-acclimatised in the tropics) and in sending me his bulletin, a very interesting publication. I do not know whether I am justified by facts in saying so, but it appears to me that exchange of plants would be very welcome; private enterprise does not seem at all equal to the delightful task that trying all sorts of half-hardy things which do well with us in summer out of doors should prove.

M. L. W.

SWEET PEAS FOR EVERYONE.

IN a very large garden of which I am lucky enough to have a key, Sweet Peas were grown last summer with such great success at such a remarkably small outlay of trouble and expense that a note or two about them seems worth recording.

To begin with, only penny packets of seed were used. Only the best sorts were ordered, the most famous that is for beauty of form and colour; novelty was not so much the consideration as a great profusion of good flowers.

In its natural state the soil of this garden is not particularly good, so by way of preparation, at each spot where the Sweet Peas were to be planted, a hole was dug out, about 18 inches in depth, and well enriched with excellent manure, for which in this case thanks must be given principally to the pig. No doubt any other good plant food would have done just as well; because one thing has proved good that is no reason why another should not be equally so. Plants do not want nearly so much fussing over as some people seem to fancy.

The Sweet Pea seeds were planted about $1\frac{1}{2}$ inches or 2 inches apart, in the form of a circle, and never more than from ten to fourteen seeds in any group. Small bushy sticks were placed around at first, which had to be exchanged ere long for very tall and stout ones, so fast the seedlings grew. Each colour was kept separate, and to each group was given a label, so that one had the satisfaction of a personal introduction to every flower as we enjoyed it. Real flower-lovers always appreciate this boon, learning to recognise the different blossoms very readily by small differences in the same way as after a time we know the individual sheep in a field, or the stars in the sky. There are the hooded Sweet Peas and the plain; and many striking differences of form and colour. A new shade or shape is noticed at once. Who could mistake the rosy red Salopian—or is it crimson, so brilliant that one fancies a sunbeam must be hiding in it—or the Black Prince, or the Navy Blue, or Emily Eckford, or the Hon. Mrs. Kenyon, which so far as I know is the yellowest Sweet Pea that we have? Lady Griseld Hamilton, hooded, of a beautiful shining lavender; Dorothy Tennant, a rosy mauve, still blooming in the open with good length of stout stem in November; Colonist, soft lilac and bright rose; Gorgeous, an orange-salmon colour, with wings of soft pink; Blanche Burpee, pure white with large blooms, and generally three flowers to a stem; Lovely, a delicate rose, described by some as shell-pink; and Countess Cadogan, violet and sky blue, are all particularly noticeable.

These Sweet Pea seeds were sown in early April; by early June there were flowers enough for picking, and during the long hot summer they never flagged or failed. There was never a day when handfuls were not ready, and the more one took the more they grew—it was the widow's cruse. A good bunch was gathered

this autumn as late as the 14th ult. There are seventeen sorts in all.

It is difficult to sum up the amount of pleasure given by these simple flowers, whose cost was really next to nothing, for in planting them one penny packet went a wonderfully long way, furnishing quite a number of the neat round rings that were afterwards such big bushes of sweetness, that it seemed a miracle so much could spring from such small beginnings. When we think of the number of Sweet Pea seeds sown every year that come to no perfection, because too many are put in at once, it is really heart-breaking. No one can say that a hedge of Sweet Peas is not a lovely thing, and when grown this way in the kitchen garden, just as we grow the edible Pea, they do splendidly. Still, the plants do not get quite so much air and light all round them thus as if grown in circular patches, and no plants take more kindly to the open-air treatment than Sweet Peas, so it is in rounds we mean to sow our own next spring.

It is impossible to pass along the scented pathway by which these Sweet Peas grow without thinking them the most joyous of all the summer flowers that blow. Their pretty wayward clusterings and flinging of soft limbs, the fragrance that invites all bees and butterflies, the hardiness that underlies their apparent fragility, their bounteous generosity, and their own so evident happiness in being alive and in full bloom, endear them to us, and bring us into sympathy with their content. One fancies that such flowers as these are born to live conscious of the heart-happiness they give.

Wishing to make these notes on Sweet Pea growing really useful, I have asked the gardener who is responsible for them to write me his directions, which I add:

"This year the Sweet Peas were planted early in the second week of April, and commenced blooming the beginning of July; but I prefer sowing fully a month earlier. My plan of preparation for them was to take out the soil, making a hole 2 feet in diameter, and the same depth, breaking up the bottom, and adding a mixture of well-decayed pig and horse manure, mixed with the soil taken from the hole, filling up to within 6 inches of the top, well treading the same, and finishing up with a few shovelfuls of good turfy loam. Then press in about ten or twelve seeds singly, about 2 inches deep and 2 inches apart, in a circle over the centre of the prepared bed. When the plants are about 1 inch above the ground place a few bushy twigs about 1 foot high around them, afterwards staking them with good stout sticks from 6 feet to 7 feet high, placing them well outside the plants, so as not to injure the young roots, watering afterwards as required, but never in dribbles. I always prefer to give a thorough soaking in dry weather, giving not less than three gallons to each clump about every ten days, afterwards (when in bloom) occasionally following that in a few hours with about a gallon of soot water in a clear state. I have used no artificial manures whatever. I consider all else that is needed to ensure continuous blooming is to remove the flowers as soon as they fade. The clumps are about 4 feet apart."

In some garden book or other last summer it was amusing to be told of a new way of gathering Sweet Pea blossoms, supposing one had no knife or scissors handy. One must hold the stalk firmly in the fingers and pull it outwards. The flower-stalk will come away from the main stem, as if from out of a socket. This seemed a useful piece of information, for few of us have failed to discover that Sweet Pea stalks are not a little tough and stringy,

and therefore difficult to gather unassisted. So we tried the experiment; one of us pulled a handful the new way, and the other cut them comfortably with scissors. The former eyed her completed nosegay with disappointment; the special charm of the Sweet Pea was quite lost to it. There was a bright tight bunch of Sweet Pea flowers certainly, but none of the tender, airy grace that comes of a bunch cut freely, with its curly tendrils, clinging fingers, and trailing sprays, just as the flowers grow. The triumphant possessor of the "scissors" posy decided it was much better to keep to the old-fashioned time-honoured method of gathering the dainty blossoms of Sweet Pea.

F. A. B.

A GENERAL CALENDAR.

CHRISTMAS DECORATIONS.

A WALK through any of our large country markets at this season of the year will afford the best possible means of seeing what materials are likely to be used for the embellishment of church or home at Christmas time. Holly, Mistletoe, and Ivy will be much in evidence, showing how tenaciously we still cling to all old customs. Choice flowers and delicate exotics will also be found in great abundance and variety. Our gardens will also yield a good supply of Berberis foliage, with its brown and bronze tints. The Box and the Yew must not be forgotten. *Ruscus racemosus* will be found useful for large vases with flowers of different kinds. Pampas Grass plumes, spikes of *Echinops*, and *Eryngium* cut from the herbaceous border in summer, with as long stems as possible, are very serviceable just now. Long dried sprays of *Humea elegans* may be mixed with these to add a little colour; they are also very graceful.

In arranging flowers beware of overcrowding and of mixing too many things together, or of using flowers of a considerable size with short stems and putting them into small specimen glasses as though they were show Dahlias intended for exhibition. Many handsome flowers are only spoilt through being crowded with short stems amongst a lot of other kinds in an undistinguishable mass. Chrysanthemums are still to be obtained in various sizes and colours. These are some of the easiest flowers to arrange. Various kinds of foliage may be used with a good result. If only overcrowding is avoided and the chosen colours do not clash, whites and yellows will be found the most serviceable.

Jasminum nudiflorum.—This Jasmine appears to be flowering with exceptional freedom. Some of the branches are completely wreathed with the clear yellow, scentless blossoms. When it was first introduced by Fortune from the north of China it was considered only suitable for indoor culture, but now, at the end of December, it brightens up many a street in the suburbs of our large towns.

Christmas Roses.—Although there is some flower beauty to be seen in the conservatory and greenhouse, the garden bereft of the white and gold of the later Chrysanthemums is desolate. It is therefore refreshing to come across a large clump of Christmas Roses, the dark green spreading leaves overtopped by dozens of large white flowers. *Helleborus niger* is far too little known, but where a good variety is once established in a garden basketfuls of white flowers may be had for the decoration of the house during winter. Christmas Roses like a deep, rich soil having a cool bottom. A border sheltered from cold wind suits them well. Opinions differ as to the best time to plant. The month of February is the best time to divide and replant large clumps, but ordinary-sized plants may be removed when in flower, and if done with care no harm will result.

Preparing Onion ground.—No time should be lost in preparing the plot intended for spring Onions. To grow heavy crops of Onions the old

mode of trenching is not the best, as in this case the manure is buried so deeply that it is a considerable time before the young rootlets reach it, whereas they require support from the first. Give a good dressing of rich manure, adding a good proportion of soot and wood ashes. Dig the ground deeply, well mixing the above-named ingredients as the work proceeds. By this means an equal mixture is secured from the top to the bottom.

Norwich.

T. B. FIELD.

COLONIAL AND FOREIGN FRUITS.

(Continued from page 414.)

MATUNDULUKA.—Under this somewhat outlandish name the fruit of *Ximenia americana* is known in Natal. The plant is a shrub or small tree belonging to the order Olacineæ, having a wide geographical range, being found in India, Ceylon, Andaman Islands, Malay Archipelago, tropical Africa, and America. The fruit is fleshy, ellipsoid in shape, 1 inch to 1½ inches long, and bright red or scarlet when ripe, though in some varieties they are yellow. They have an acid-sweet aromatic taste in some forms, and before they are fully ripe they are slightly bitter. The skin is thin, but the flesh is firm and abundant, and the appearance of the fruit in its ripe state has much to recommend it. Preserve made from it in Natal has proved to be very good, and both fruits and preserve might find a market here.

JUJUBES.—The Indian Jujube or Chinese Date (*Zizyphus Jujuba*) is a tree from 30 feet to 50 feet high, growing throughout India, Ceylon, and Malacca, both wild and extensively cultivated, and found also in Afghanistan, Malay Archipelago, China, Australia, and tropical Africa. The fruits vary considerably in size, shape, and quality, according to the variety grown, though they never exceed in size that of a medium-sized Gooseberry. It is very fleshy when fresh, becoming mealy as it dries, and though strongly acid is very pleasant to the taste. It is largely eaten by the poorer classes in India. All the varieties are of a sweetish-acid flavour and very palatable. In the Deccan famine of 1877-78, the fruits of the Indian Jujube were powdered and made into a kind of meal, which was largely consumed as food. The pulp of the dried fruits mixed with salt and tamarind is used in India as a condiment, while the unripe fruits are pickled.

The common European Jujube (*Zizyphus vulgaris*) is a shrub or small tree, sometimes growing 20 feet high, and widely cultivated in Spain, Italy, and the South of France for its fruits, as well as in India, China, and Japan. These fruits resemble those of the foregoing species, changing as they ripen from green to red, and having a sweet acidulous taste. They are gathered in September and carefully dried for use as a dessert fruit. Jujubes are not

unfrequently seen in English shops preserved in bottles in the dry form, and sometimes in syrup; they are always, however, more or less scarce and high priced.

AKEE (*CUPANIA EDULIS*).—This tree is perhaps better known as *Blighia sapida* from having been named after Captain Bligh of H.M.S. "Bounty." It grows to about 30 feet high, and is a native of Upper Guinea, from whence it has long been introduced into the West Indies and South America. The fruit, which is of a red colour tinged with yellow, is fleshy, about 3 inches long and 2 inches in diameter: it is somewhat three-sided, opening when ripe into three divisions longitudinally and exposing the three hard, black seeds, one of which is contained in each division. These seeds are

Both plants belong to the same natural order—Sapindaceæ.

GENIP (*MELICOCCA ELIUGA*).—This is a beautiful branching tree, 40 feet to 50 feet high, belonging to the same natural order as the last. It is a native of Guiana and New Grenada, but has been introduced into the West Indies, where, especially in Jamaica, it has become naturalised and is now abundant. It produces numerous fruits of a green colour, in shape and appearance somewhat like Bullace Plums. The pulp is described as having a deliciously sweetish-acid and slightly aromatic taste. The tree flowers in April and May, and the fruit is in perfection in August. Though the fruits of the Genip are not known in English commerce, they have appeared at

different times among collections of fruits from South America and the West Indies at the several international exhibitions.

MALAY APPLE, ROSE APPLE, and JAMBOLAN are names given respectively to the fruits of *Eugenia malaccensis*, *E. jambos*, and *E. jambolana*, plants belonging to the Myrtaceæ, and closely allied to the Guava. The Malay Apple is a handsome tree with a profusion of white or scarlet flowers, succeeded by an abundance of fruit about the size of a small Apple, soft and juicy, and in its fresh state rather insipid, but generally eaten and considered very wholesome in the countries where it is grown. Though the tree is a native of the Malay Islands, it has been introduced into most tropical parts of the world, and is very extensively cultivated in gardens in Bengal and Burma. A number of varieties are known with fruits of different sizes and colours. The Rose Apple is a moderate-sized tree extending through India, Burma, and Penang, to Australia, and cultivated abundantly in India and the West Indies. The fruit is somewhat similar to the last named, but has a distinct flavour of Rose-water, hence its common name. It makes an excellent preserve, and being very productive might be turned to good account. The fruits themselves are probably of too soft a nature to be brought to this country in a fresh state. An attempt was made many years ago to introduce them in a candied or crystallised form from Jamaica, having been first exhibited in this state amongst a collection of West Indian fruits at an exhibition in Philadelphia, where a silver medal was awarded

THE EDIBLE PASSION FLOWER (*PASSIFLORA EDULIS*). (Reduced)
From a drawing by Miss Lillian Jackson.

partially buried in a white or pinkish-tinted fleshy socket or aril; this is the edible part of the fruit, and when fully developed and quite ripe it is said to have delicate agreeable sub-acid taste, very grateful to the palate, and melting in the mouth. The fruit seems to require the heat and other conditions of a tropical climate to bring the pulp to perfection, as fruits ripened in hot houses in this country have failed to develop the flavour attributed to it by travellers. The nuts, like those of the Litchie, which were described in a previous paper, are too soft for importation in their fresh state, but might be preserved in syrup,

to them. From this they were introduced to notice in London, and a large quantity was immediately asked for, but as this could not be supplied at once, there being no means of candying on a large scale in Jamaica at the moment, and the perfection of this art belonging essentially to the French, candied Rose Apples lost their chance, and nothing has been heard of them since. As the season for these fruits in the West Indies is in August and September the candied fruits might well come into the English market at this, the best season of the whole year, namely, Christmas.

The Jambolan is a moderate sized tree, found wild or under cultivation all over India; it has also been introduced into the West Indies, where it is said the trees have been propagated in consequence of the favour with which the fruits have been received. In India it flowers at the beginning of the hot season, and the fruits ripen in July and August. They are usually about the size of a pigeon's egg, of a purple colour, with a slightly astringent sub-acid taste. The fruits are said to be improved by being pricked, rubbed with a little salt, and allowed to stand for about an hour. In Goa a wine is made from them. In the genus *Passiflora* we find several species producing edible fruits.

JOHN R. JACKSON.

(To be continued.)

ROUND ABOUT A GARDEN.

THE COMMON OR GARDEN EVERGREEN.

DURING December the only use which most of us have for a garden is to look at it through the window now and then to see if the rain has stopped. For this purpose evergreens of the Cypress type are very useful, because against the intensely black interspaces of the foliage the finest drizzle can be clearly seen. Perhaps this is why so many of these funeral plants are usually stuck round our houses by way of shrubbery, for one cannot see any other merit which they possess over other evergreens which are quite as hardy and twice as pretty, yet a hundred times more seldom seen. In gardening, more than in anything else almost, it seems difficult to get out of established ruts. Visit a nursery and you will see all the familiar plants growing by hundreds, but if you want to see something better you will be taken to out-of-the-way corners where the best things are grown in small groups only, because they are so seldom asked for. Loyalty to old favourites is sometimes enlogised as a British merit, but in most cases it arises from sheer ignorance of the newer and better, combined with laziness which prevents us from taking the trouble even to find out what we would like.

MONOTONY OF SMALL GARDENS.

And this frame of mind reacts upon the conduct of the hired gardeners whom dwellers in villadom employ. Accustomed to deal with patrons who have never taken the trouble to learn even the names of half-a-dozen garden shrubs, the gardener steers his safe and easy course round a small circle of familiar things, which can be bought anywhere by the half-dozen and be dotted about in as many gardens.

Hence the dismal uniformity of rows upon rows of gardens, which, though they may collectively cover as much ground as Kew Gardens, have not between them as many varieties of pleasing plants as would there be put into a single shrubbery group. The cult

of the common evergreen is, in fact, the bane of British gardening, and we shall not get rid of it until we begin to take a personal interest in the garden work of winter. For now is the time when we can safely plant anything that we like for the beauty of the garden next year and many years to come.

REPEATING PAST BLUNDERS.

In the matter of trees, again, why should the sole timber of our small gardens almost always be common Elm, common Horse Chestnut, common Lime, or common Sycamore? Massed and grouped in a wild park these weed trees

ROSELLE (HIBISCUS SABDARIFFA). (Reduced.)

See "The Garden" of the 17th inst., page 415.

may be effective enough, but individually occupying a large part of a small garden, which might have been so easily filled with something better, each of them is matter in the wrong place.

To remove a large tree is, however, a serious matter sometimes, and to this extent a present owner must often be content to suffer for the errors of his predecessors. What is really wrong is that we ourselves take so little thought of avoiding the same blunders. How many owners of gardens think in the first instance of planting beautiful trees which will be a growing beauty to the neighbourhood for many decades?

NEW TREES FOR OLD.

Instead of allowing a wild Sycamore sapling to thrust itself up in the heart of a shrubbery until it vulgarly dominates the whole garden, why not prepare for the future by planting there and carefully tending some tree of striking foliage and graceful habit? The Sycamore itself has Maple cousins in plenty which would attract attention by their beauty anywhere. The common Oak, too, has relatives with richer foliage and bright autumn tints. There are Limes much more striking in aspect than the common kind, without its bad habit of beginning to drop its leaves soon after midsummer. There are Poplars golden and silvery, and Maples purple and red. The Weeping Elm is a thing of grace compared to the common "escape" from the hedgerow, and the Weeping Birch, standing alone, is always a picture of loveliness. Why let the common Horse Chestnut rankly cumber the ground, when its near relatives, the Pavias, are far better fitted to fill the space available in a small garden with a town atmosphere? And of smaller trees, with blossom of every shade and leaves of every shape and hue, there is material for well-arranged effects of colour at every season of the year. In this scheme some well-chosen evergreens, ranging from silver or golden yellow to blue-black, would play a happy part, and be far more pleasant to contemplate in winter than the banked Laurels and Cypresses standing in rows like policemen, which seem now to express the average householder's idea of garden beauty in midwinter. It is never too late to mend, however, and anyone who now decides to put into his garden a few young trees of exceptionally beautiful kinds, with due attention to the contrasts and harmonies of their appearance together in later years, will be doing work which will bear a richer profit in pleasure than anything which costs so little effort at any other season.

THE USE OF COMBINATION.

Above all, one should not forget the double effect of beauty which can be achieved by the use of flowering climbers upon trees of suitable growth. An early white Rose trained upon a scarlet Hawthorn or the Wistaria showering its pale mauve blossoms with the Laburnum's golden rain make simple combinations which any one with a little thought can multiply indefinitely; and surely, when your friends note how beautifully two or more of your plants grow together, it will not lessen your pleasure to know that you had placed them together for that purpose. If we gave half the thought in December to the future arrangements of our trees and shrubs that we devote in previous months to the grouping of our bulbs and hardy plants for the spring garden, we should be laying the foundation of pleasure which would not be exhausted in any season, nor, indeed, in any lifetime. The careful use of evergreen shrubs is not sufficiently practised by gardeners.

E. K. R.

THE ROSE GARDEN.

ROSE FURBENKONIGIN.

At any time the beautiful colour of this new Hybrid Tea is remarkable, but especially so in late autumn. Most Roses take on a deeper hue in autumn, and this one comes almost a red then. It is very fragrant, possesses many of the characteristics of La France, and as a winter bloomer will be a great gain. All who force Roses would do well to add Furbenkönigin to their collection. We have received several splendid Roses from Germany, and this beautiful novelty, although not quite of the same excellence as Frau Karl Druschki or Snow Queen, which it is sometimes called, and which would have been a far better name for it, will rank as a Rose of no mean merit. How superior for garden decoration such Roses as these are to the, perhaps, more magnificent show varieties of the Mildred Grant type. We see the latter heading the list in the Rose analysis of the present year, yet as a cut-back the variety is a failure. I have not seen one respectable flower of Mildred Grant upon a two year old plant. I know it is magnificent as a maiden, and as such it will probably be grown. Those who would plant it as a bedder would be wise not to do so, but rather plant such Roses as the one under notice. The good varieties are so abundant that there is no need to have any that are at all doubtful. P.

A ROSE HEDGE.

A Rose hedge is shown in the accompanying illustration, but it is hoped in time to train the growths along the wires that are shown. These Roses are not of the cut-back, closely-clipped nature that the word hedge signifies, but they are loosely trained so as to form a natural and graceful growth of greenery and flowers. When the Roses have made a fuller growth, covering the wires overhead, this garden scene will be still more beautiful. The association of a grass walk, a paved path with flowers in the chinks, pools of water, and boundaries of Roses is a happy one, and time will add to its effectiveness.

ROSES FOR BEGINNERS.

We have taken the following list of Roses for beginners from a pamphlet just issued by the National Rose Society, and the lists have been compiled from returns sent in this year by the leading amateur and professional rosarians of the day:—

FIFTY ROSES FOR EXHIBITION.

Hybrid Perpetuals and Hybrid Teas.—

White: Frau Karl Druschki. Creamy white: Bessie Brown (H.T.), Mildred Grant (H.T.), Kaiserin Augusta Victoria (H.T.), Alice Lindsell (H.T.), Florence Pemberton (H.T.). Pale rose or pink: Mrs. John Laing, La France (H.T.), Mrs. W. J. Grant (H.T.), Mrs. R. G. Sharman-Crawford, Caroline Testout (H.T.), Her Majesty, Killarney (H.T.). Medium red and rose: Ulrich Brunner, Suzanne M. Rodocanachi, Marquise Litta (H.T.), Gustave Piganeau, Dupuy Jamain, Helen Keller. Crimson: A. K. Williams, Alfred Colomb, Captain Hayward, Marie Baumann, Comte de Raimbaud, Victor Hugo. Dark crimson: Charles Lefebvre, Horace Vernet, Duke of Wellington, Prince Arthur.

Teas and Noisettes.—White or cream: White Maman Cochet, The Bride, Muriel Grahame, Innocente Pirola, Souvenir de S. A. Prince, Souvenir d'Elise Vardon.

Blush, pale rose, or pink: Maman Cochet, Catherine Mermet, Mrs. Edward Mawley, Bridesmaid, Mme. Casin, Mme. de Watteville, Cleopatra, Ernest Metz, Souvenir d'un Ami. Yellow, buff, or orange: Mme. Hoste, Maréchal Neil (N.), Comtesse de Nadaillac, Souvenir de Pierre Notting, Anna Olivier, Medea.

N.B.—In the above list of exhibition Roses the varieties have been arranged under the different colours, according to the returns sent in, in their

order of merit, with a view to assist those amateurs who require only a small number of sorts.

SIXTY ROSES FOR GARDEN DECORATION.

"Summer-flowering" varieties, or those which bloom only once in the year.

Provence.—Pink: Cabbage or common.

Moss.—White: Blanche Moreau. Pink: Common or old.

A HEDGE OF ROSES.

Damask.—White, striped red: Rosa Mundi.
Austrian Briar.—Coppery red: Austrian Copper.
 Yellow: Austrian Yellow.
Sweet Briar.—Coppery yellow: Lady Penzance.
 Dark crimson: Meg Merrilies. White, tipped
 crimson: Janet's Pride.

Climbing Roses.—White: Félicité Perpétue
 (Evergreen), Bennett's Seedling (Ayrshire). Blush:
 The Garland (Hybrid China). Pink: Leuchstern
 (Climbing Polyantha). Crimson: Crimson Rambler
 (Climbing Polyantha), Carmine Pillar (Single).
 Yellow: Claire Jacquier (Climbing Polyantha).

Trailing Roses.—Lemon-white: Jersey Beauty.
 Pink: Dorothy Perkins.

"Autumn-flowering" varieties, or those which bloom
 both in the summer and autumn.

Hybrid Perpetuals.—White: Frau Karl Druschki.
 Pink: Mrs. John Laing, Mrs. R. G. Sharnman-
 Crawford. Rose: Suzanne M. Rodocanachi.
 Cherry-red: Ulrich Brunner. Crimson: Captain
 Hayward. Dark crimson: Prince Camille de
 Rohan.

Hybrid Teas.—Creamy white: Viscountess
 Folkestone. Pink: La France, Caroline Testout,
 Killarney, Mme. Abel Chatenay. Crimson: Griss
 an Teplitz. Yellow: Gustave Regis, Mme. Ravary.

Bourbon.—White: Souvenir de la Malmaison.

China.—White: Mrs. Bosanquet. Pink and
 rose: Laurette Messing, Mme. Eugène Resal, Old
 Blush or common Monthly. Crimson: Fabvier.

Teas.—White: White Maman Cochet, Souvenir
 de S. A. Prince. Pink and rose: Maman Cochet,
 Mme. Lambard. Yellow: Marie van Houtte,
 Souvenir de Pierre Notting, Mme. Hoste.

Polyantha.—White: Mme. Anna Marie de Mon-
 travel. Pink and rose: Cecile Brunner, Gloire
 des Polyantha. Yellow: Perle d'Or, Eugénie
 Lamesch.

Japanese.—White: Blanc Double de Coubert,
 rugosa alba.

Perpetual Scotch.—Blush: Stanwell Perpetual.
Climbing Roses.—White: Mme. Alfred Carrière
 (Hybrid Noisette). Crimson: Longworth Rambler
 (Hybrid Tea), Reine Olga de Wurtemberg (Hybrid
 Tea). Yellow and buff: William Allen Richard-
 son (Noisette), Gloire de Dijon (Tea), Rêve d'Or
 (Noisette).

The varieties in the above list of Roses for garden
 decoration have been arranged under the different
 colours, according to the returns sent in, in their
 order of merit, with a view to assist those amateurs
 who require only a small number of sorts.

ROSE AIMEE VIBERT.

How beautiful this fine old Rose is in September,
 and it goes on flowering right into the late
 autumn. It is a great success when budded upon a
 short, medium, or tall standard Briar. I met with
 one last summer in a cottage garden and it was the
 picture of health, the fine, glossy green foliage
 contrasting so admirably with the bunches of snow-
 white blossom. Upon a very tall stem this Rose
 looks well, and it quickly develops a very large
 head. It has not exactly the weeping habit of the
 Ayrshire Roses, but in time the weight of the
 branches causes them to bend over so that the stem
 is partly hidden. It is a Rose that should be
 afforded plenty of space, for then its fine propor-
 tions are seen to the best advantage. Naturally,
 such a fine climbing is suitable for planting against
 a pillar. It does not run up very high, but it
 becomes dense at the base, and therefore the old
 and useless wood should be well thinned out,
 retaining their full length the one and two year
 old growths. P.

WICHURAIANA ROSES AS EVER- GREEN CLIMBERS.

It is quite refreshing to come across the glistening
 foliage of some of the best of this group in Novem-
 ber, and more especially when the plants are
 drooping their long trails gracefully from some
 spurred Larch poles or other supports. That they
 will take the place of Ivy in many cases seems to
 be evident. I would even recommend them to be
 planted upon the same pillar as certain climbing

Tea and Noisette Roses, mainly for the evergreen
 effect they would give. There would be nothing
 incongruous about such pillars, and a little skill
 in regulating the growths would prevent undue
 encroachment of the wichuraianas. Some indi-
 viduals even lament that the wichuraianas are so
 aggressive, but surely the pruning knife can regu-
 late this without in any way robbing the plants of
 their beauty. Where they encroach too much
 upon the rock garden or roostery the growths may
 be pruned hard back, as new ones will appear with
 foliage even more glistening by reason of their
 greater vigour. Just now Jersey Beauty, Rene
 André, Alberic Barbier, and Dorothy Perkins are
 very charming with their varnished-like leaves,
 and some of the newer sorts, such as alba rubri-
 folia, are none the less attractive. This latter
 yields also a neat, waxy-petalled flower like a
 miniature Hon. Edith Gifford. Edmond Proust
 reminds me of Perle d'Or, and Elisa Robichon
 has flowers almost equal to those of a show bloom.
 If anyone has an old Thorn bush, isolated and
 in a prominent position, let him plant one of
 these wichuraiana Roses in a prepared hole close
 by it, and in a year or two this bush will be very
 graceful. There are many positions upon a large
 estate that could be beautified with the help of
 these charming evergreen Roses. P.

THE FRUIT GARDEN.

APPLES FOR PROFIT.

TO those contemplating the planting
 of Apple trees for profit, apart
 altogether from the pleasure or
 interest which attaches to possessing
 a number of varieties, the past
 season, by reason of the bountiful
 crops we have had, has taught a valuable lesson
 as regards the selling value of some varieties of
 Apples over others. Although the Apple crop
 has been a heavy one, the growers have profited
 little, in consequence of prices ruling so low.
 From many parts of the country deplorable
 accounts have been heard of low prices. In
 many cases they were so low as not to cover
 the cost of gathering and marketing. But one
 variety has been a conspicuous exception. I
 need scarcely say that that variety is Cox's
 Orange Pippin. I was told a few days ago by
 one of the largest salesmen in Covent Garden
 that although there had been a glut of Apples
 in the market, and a slump in price in conse-
 quence, that Cox's Orange Pippin had main-
 tained a high price throughout the season, and
 that good samples at the present time are
 making from 16s. to 20s. per bushel. I saw
 this variety offered for sale in a West End
 fruiterer's window at the price of 3s. 6d. for a
 basket of eight! A gentleman about to plant
 some Apple trees for profit this winter made it
 his business to enquire from experts in fruit
 culture which was the best Apple to grow for
 sale. Each one, without exception, recom-
 mended Cox's Orange Pippin, and I earnestly
 endorse their recommendation.

Those about to devote land to the culture
 of Apple trees should plant this variety by the
 acre. There is no other Apple, home-grown or
 imported, which can approach it in quality or in
 market value, and there is no danger—at least,
 in our lifetime—of the supply ever being larger
 than the demand. It does not grow into a
 large tree as quickly as some sorts, and for this
 reason the trees may be planted closer together
 than those of more robust habit. Eighteen feet
 apart each way (measuring between tree and
 tree in the row, and the same between the rows)
 in the case of orchard standards or 9 feet
 between bush trees is sufficient. If the fruit
 is harvested with care and kept in a cool fruit
 room that is not too dry, this Apple will remain

in good condition for table and market for at
 least four months, from October to February.

OWEN THOMAS.

HARDY FRUITS IN SEASON.

PEAR KNIGHT'S MONARCH.

THIS Pear is, perhaps, the least known of all the
 really excellent and hardy Pears, because it is of
 such ill-favoured appearance that one rarely sees
 it upon the exhibition table. Few Pears vary more
 in different seasons than this variety, but this year,
 owing to the good summer, it is of great excellence.
 It is not merely that the flavour is indifferent in an
 adverse season, but many of the fruits shrivel
 instead of ripening. It is a good bearer, and forms
 a handsome pyramid, though the growth is thin
 and wiry. It succeeds well upon the Quince stock,
 but is usually double grafted to ensure early fer-
 tility. It has one remarkable characteristic which
 makes it ill adapted for a standard, and that is its
 habit of dropping its fruit from the end of August
 onwards. This falling is not really premature as a
 rule, but is owing to the uneven ripening of the
 fruit, some being ready to gather the beginning of
 September and some not till the middle or latter
 part of October. It is recommended that the fruits
 should be gathered as they are ready, at intervals
 of a week from the early part of September onwards.
 The result is a very extended season, more so than
 that of any other dessert Pear, as it can be had in
 good condition from early November to the end of
 February. The Pear is of medium size (sometimes
 large from pyramids), russet in appearance, and
 varying in shape. It was raised by Mr. Knight
 early last century, and called the Monarch because
 he believed it to be the best of all Pears then in
 existence. It had a great vogue, and another Pear
 was largely sent out under the same name, which,
 strange to say, has the same habit of dropping its
 fruit. This spurious variety (some say there are
 two or three) is inferior in flavour to the true one,
 though not without merit. It is easily distinguished
 from the true one by the smaller amount of russet
 upon it (often scarcely any) and by the young
 shoots, which in the spurious variety are yellow,
 but in the true a dark violet. Reliable nursery-
 men can be trusted nowadays to send out the true
 variety, but it is the old standards fifty or sixty
 years old that are so often untrue, the spurious
 variety making a specially fine tall tree.

APPLE THE QUEEN.

OF Apples introduced during the last thirty years
 this has probably attained as great a vogue as any,
 at least to judge by the frequency with which it is
 seen upon the exhibition table. It was raised in
 Essex, and the raiser tells me that the crops from
 the original tree have paid for the freehold of the
 ground it occupies many times over. The tree is a
 good grower, and, though very fine fruit is pro-
 duced on dwarf trees (it makes a spreading bush),
 it is better adapted to the standard than any other
 form because of its tendency to produce the finest
 fruit upon the previous year's wood, often at the
 very tips of the shoots. For this reason, too, it
 should not be planted in too exposed positions or
 much of the fruit will be blown off. The falling of
 the fruit is rather an objectionable characteristic,
 as this often begins the latter part of August,
 though the main part of the crop will remain upon
 the tree till the third or fourth week in September.
 It is a very fair cropper, though the manner of
 bearing and the somewhat slender character of the
 growth prevent a tree carrying such a heavy crop
 as some varieties do. It is of spreading growth,
 and the branches naturally get weighed down still
 further by successive crops. It is one of the earlier
 varieties to come into flower, and therefore is not
 well suited for low-lying localities. It began to
 flower last spring on the 3rd of May, Scarlet
 Nonpareil beginning on the 7th, and Lemon Pippin
 on the 9th. It is a light Apple, a bushel not
 exceeding about 40lb. Thus it shrieks very much
 in cooking. It should have a slow oven for baking
 or it will burst all to pieces. It is very juicy, and
 owing to its lightness of texture cooks very easily.
 It is at its best for cooking during October and
 early November, getting very frothy in late

December, though this is regulated a good deal by the time of gathering. If allowed to hang till the middle or latter part of September it makes a very fair dessert Apple in October in some seasons for those who like a rather acid Apple, being very tender and juicy. It can be broken into quarters with the greatest ease, and the skin is very thin. For those who want an Apple for mixing with Plums or Blackberries for jam there is none more suitable than this, owing to its attaining a good size early in the season and boiling down very easily.

ALGER FETTS.

NOTES ON HARDY PLANTS.

NIEREMBERGIA RIVULARIS.

THIS hardy perennial came from Argentina in 1866: it is a creeping plant, roots abundantly, and forms dense masses of white *Convolvulus*-like flowers $1\frac{1}{2}$ inches across borne on slender stems. In its native country, on the Plate River, it grows in great abundance by the riverside, but in this country it does not do well in damp places. Good strong loam suits it best, and a full south position, but a little peat and leaf-mould added as a top-dressing will be found very beneficial. It is a surface-rooting plant, and requires this little addition to help the young growth. *N. rivularis* is a fine subject for planting in a south position on sandstone or gritstone rockwork, where it should be in broad patches to obtain the best effect. This plant is of easy cultivation when planted in the right position, and deserves more notice than it at present receives. The photograph is of a patch covering nearly three square yards in the nurseries of Messrs. J. Buckhouse and Son, Limited, York.

NIEREMBERGIA RIVULARIS IN THE YORK NURSERIES.

who did: at the same time it must be remembered that one Potato weighing, say, 16oz. may be quite as good in quality as another at 8oz. I recollect staging on one occasion a lot of *Syon House Prolific*, each tuber being either just a little over or under 15 inches in circumference. They were of splendid appearance and equally good to eat. E. L. B.

[TO THE EDITOR OF "THE GARDEN."]

RANUNCULUS AMPLEXICAULIS.
THOSE who are seeking for a choice plant for the cool rocky or alpine house should try this *Ranunculus*, one of the loveliest of spring flowers, and surprisingly effective when well grown. The leaves are Plantain-like, the stems branching and 1 foot or more high, bearing pure white flowers as large as a florin very freely. It is a difficult plant to treat in open, exposed places, and the long white roots clearly indicate love of moisture. One could grow it well with *Ferns*, *Narcissus triandrus*, or *N. Bulbocodium*. It delights in peat or leaf-soil, and when pot-grown should have plenty of root-run, for it is impatient of drought. I have had it in effective association with *Shortia galacifolia* and *Galax aphylla*, the combination being exceptionally pleasing in flowering time, whilst the site is never bare when the *Ranunculus* dies down. It is an old-time plant hailing from Southern Europe, yet rarely in evidence in the best gardens. G. B. M.

SIR,—Without going into the merits or demerits of the Potato show at the Crystal Palace as an educational factor (although I would mention in passing that I think the National Potato Society is doing more valuable work in other directions), I should like to say a word or two with reference to the opinions that have been expressed in THE GARDEN upon the quality of yellow and white-fleshed Potatoes. It seems to me that the choice between these is largely a matter of individual taste, and the fact that one person may consider a yellow flesh Potato to be immeasurably superior to one with a white flesh does not necessarily make the latter inferior, and *vice versa*. Personally, I prefer the white-fleshed tuber, as I think the majority of Englishmen do. My recollections of Potato salads in France, and during a two years' residence in that country I must have partaken of many, are not such as to make me look back with pleasure upon a dish that figures largely in the menu of the French. The yellow-fleshed Potatoes are cut into slices, served cold, and covered with salad oil. I never could bring myself to appreciate them. It is a fact that some persons (whose cultured taste cannot be called in question) prefer *Gros Colmar* Grape to the *Muscat* of Alexandria, but for that reason I should hesitate to say that *Gros Colmar* was a better flavoured Grape than the other. Or to take the comparison one step further, some people prefer an Apple that has an acid flavour to that of sweeter taste, yet this does not alter the value of either the one or the other. So, if some prefer a Potato whose flesh is of the consistency of flour, while others like the tuber whose flesh is wax-like, it seems to be a question of the taste of the individual. I fail to see because the white-fleshed tuber has triumphed that it proves the standard of public taste to have fallen. P. H.

TROPEOLUM SPECIOSUM.

[TO THE EDITOR OF "THE GARDEN."]

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondent.)

POTATOES TO EAT.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—There seems a consensus of opinion that Windsor Castle and Up-to-Date Potatoes are from the generally accepted standpoint of quality very good indeed. Mr. Engleheart says it is only a depraved taste that accepts them. I read on page 373 of the floury Potato that it is used "as a sponge to mop up gravy." On the contrary, the lover of a good floury Potato does not allow it to come in contact with gravy, but has it either boiled or baked in its skin, cuts it asunder, and eats it with the addition of pepper, salt, and a little butter. I was, unfortunately, unable to go to the Potato show, and cannot say anything as to whether, in judging the exhibits, favour was shown to tubers of gigantic rather than of moderate size. I have never favoured such ruling, and do not remember ever coming in contact with a good judge

creeping underground stem. This is precisely where the mistake is generally made. Although quite a nuisance in places where it luxuriates, this brilliant Flame Flower is very impatient of disturbance. That the plants made "nice growth" the first year proves nothing, except that the "tubers" were vigorous and healthy, and that the growth was the result of drawing upon the nutriment stored in the fleshy stems during the previous year. Conscientious nurserymen, with a reputation to sustain, do not supply loose "roots" of plants of this character, and no doubt "W. S." would experience no difficulty in procuring plants of *Tropæolum speciosum* established in pots. In Messrs. A. Bee and Co's nursery at Neston, Cheshire, this brilliant climber is growing vigorously in two places. The first is in the usually recommended position—at the foot of a north wall, where the plant flowers and produces quantities of seeds. The second is on a raised bank in the herbaceous border in full sun, where the growths cover an area 8 feet or 10 feet in diameter. Here twiggy branches are thrust into the ground, and to these the multitude of growths cling. Though not attaining a height of more than from 3 feet to 4 feet there is no question as to the vigour of the annual growths. E. H.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I can confirm Mr. J. R. Jackson's statement (page 317) that the Flame Flower is to be met with in the best of health in certain gardens in the south-west. I have never seen it doing better, even in Scotland, than in a garden about two miles from Plympton, South Devon, where large plants occupy a north wall in company with *Lapagerias* (red and white) and *Berberidopsis corallina*. In the same garden another plant of this *Tropæolum* is doing well against the trunk of a very large and old Silver Fir, and is now climbing among the branches. Failures, however, I fear, exceed successes in the south of England. It grows with me, but entirely lacks the vigour of the specimens I have alluded to. Overhead evergreen shade appears to suit it to perfection. In a garden that I know there is a long hedge of *Berberis stenophylla* edging a lawn. The *Tropæolum* was planted at the roots of the *Berberis* along the entire length of the hedge, and has increased to such an extent that in the summer, after the flowers of the *Berberis* are over, the whole hedge, about 10 feet in height, is a blaze of vermillion. In a friend's garden numbers of tubers were carefully planted in prepared soil in several selected spots and well tended and watered in dry weather. A few tubers being left over, a cut was made with a spade at

the base of a *Rhododendron* bush, the tubers inserted into it, stamped upon, and promptly forgotten.

In spite of the care lavished upon them, all the plants furnished with special soil and given apparently favourable positions died in the course of two years, but in the third year the owner of the garden described a trail of scarlet on a *Rhododendron*, and upon examination found that the superfluous tubers, that had been hastily planted and forgotten, had not followed the bad example of their more carefully nurtured relatives, but had made continuous growth until their shoots emerged at the top of the bush. From that time they have made continuous progress, and now cover a group of *Rhododendrons* for many square yards.

S. W. FITZHERBERT.

VITALITY OF SEEDS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—You may care to publish the following letter which we recently addressed to the editor of *The Times*: "It may interest you to know that Captain Scott took out a collection of vegetable seeds in the steamship *Discovery* in 1901 with a view to their being found useful during his stay in southern climes. Some unused portions of these seeds have lately been returned to us by Dr. Koettlitz, botanist to the expedition, and we are surprised to find so little deterioration in the germinative power. Out of 100 seeds our botanist reports that Radish produces 92 per cent., Lettuce 85 per cent., Turnip 96 per cent., Onion 71 per cent., Mustard 96 per cent., and Cress 92 per cent., and this notwithstanding the fact that they have passed twice through the tropics and have been exposed to the low temperature of 40° Fahr. (72° below freezing point). After passing through such vicissitudes this enduring vitality can only be put down to the fact that the seeds were specially dried according to the system we employ with all garden seeds intended for the tropics. By our peculiar process excess of moisture is extracted without injury to the germ, and we find when certain seeds are so treated their tenacity to life under the most varying conditions is extraordinary. We also pack such seeds in hermetically sealed receptacles, from which the air is thoroughly exhausted. Photograph No. 175 in the expedition's exhibition, now open at the Bruton Galleries, illustrates some boxes of Mustard and Cress in full growth in the most southerly point at which English seeds have ever sprouted.

"High Holborn. JAMES CARTER AND CO."

GARDENING OF THE WEEK.

FLOWER GARDEN.

A BRIGHT CORNER.

IN some gardens during December one looks in vain for a touch of bright colour. In its season the spring garden is gay; throughout the summer and autumn the flower-beds and herbaceous borders are full of showy flowers. But after the frost has killed the Dahlias and the deciduous shrubs have lost their autumn tints, there ensues what may well be termed a close season until the early bulbs come in. True there are a few so-called winter-flowering shrubs, but it is only in mild seasons that they are valuable. This year the Winter Sweet has had all its early buds destroyed, and it will be some time before the *Laurustinus* is in flower. In the woods on the outskirts of the garden there is often more to gladden the eye. The gales have stripped the deciduous trees of their last remnant of autumnal colouring, but this only serves to disclose more fully the glorious red bark of the tall Scots Firs—which, by the way, are not Firs at all, but true Pines, although the first name comes much more readily. When lighted up by the setting sun these trees literally blaze with colour and warmth. Below, the Hollies bear an unusually large crop of berries, which the voracious birds are now rapidly depleting. Admittedly beautiful as are many of the

SILVER AND GOLD-LEAVED FORMS

and those which bear yellow berries, yet none of them can replace the common Holly, which, with its bright berries and cheerful shining leaves, is so much in request at the present moment. At the margin of the wood are clumps of the Pincushion or Spindle Tree. The poorer the soil the more freely it fruits. Its leaves have long changed colour and fallen, exposing the clusters of scarlet fruits from which project the orange arils of its seeds. In vacant spaces we have planted clumps of the common Furze, and our picture is now complete. On a smaller scale much of this brightness may easily be reproduced in the garden. Although only native shrubs,

THE FURZE AND SPINDLE TREE

are valuable, and to the former should be added the double-flowering variety. In the background several of the berry-bearing Thorns must find a place, and then must come a large clump of *Cotoneaster Simonsii*. This most valuable shrub may be termed sub-evergreen for it rarely loses all its leaves during the winter. It is probably the latest shrub to turn colour, and just now, even though most of its red berries have gone, the mixture of bright green leaves at the extremities of its branches and the scarlet ones in the body of the shrub makes it strikingly beautiful. The trailing *C. microphylla* will be of great use towards the front of our group, and Loudon's advice of "grafting it standard high on the Thorn" might well be followed. There are several species of *Rosa*, especially the Sweet Briar, which if kept pruned to compact bushes produce masses of brightly coloured hips, and *Pyrus japonica* if treated in the same manner will generally flower fairly well during the winter. There are several *Barberries* of value for our purpose. The two best are probably *Berberis Aquifolium* and *B. vulgaris*. In any vacant spaces in the foreground a few clumps of *Physalis Franchetti* will add greatly to the effect.

INDOOR GARDEN.

AMARYLLIS.

KEEPING the bulbs of these too dry whilst at rest and allowing them to shrivel is often the cause of their failing to produce flower-spikes, though during the winter months no more water than is necessary to keep the bulbs plump should be given. The temperature in which they are situated should range about 45°, and the atmosphere should be perfectly dry and sweet. Overhaul occasionally the stock of bulbs, and select from them any that are beginning to develop their flower-spikes, and remove these to a temperature of 55° to 60°. The dry soil about their roots should be well soaked with water, and the atmosphere of the house in which they are placed should be kept moist by syringing. Stimulants in the shape of liquid manure, as well as a little of Clay's Fertilizer, will promote a robust growth, but in no case apply it unless root-action be free and healthy. Those bulbs that have been longest at rest will produce their flower-spikes the first, and it is advisable periodically to inspect the stock.

WHITE CHRYSANTHEMUM FLOWERS

cannot during Christmas time be produced in too great a quantity, and as the variety *Niveus* at the present time is producing flowers in abundance, it is recommended as the best to grow for the purpose. Obtain and propagate the cuttings as soon as possible, and what are called sucker or root cuttings are the best, as the leaves of plants propagated from stem-cuttings frequently turn yellow and fall off during the growing season. Excellent dwarf plants are produced by striking the tops of shoots early in June, three to five, in a 4½-inch pot. These after being rooted should remain, and be grown until they flower in the same pots.

THE AZALEA HOUSE.

Although it is unwise to allow the temperature to fall below 35°, it is advisable not to maintain a greater warmth at this time than 40° to 45°, with plenty of air. Care also must be exercised in

affording the plants water, as keeping the soil about their roots too wet will encourage growth, which if allowed to advance would seriously cripple the prospect of the flowers opening satisfactorily, and if the new growths be ripped out, which is often done in the case of exhibition plants, the general health of the plants would suffer. Remove those plants the flower-buds of which are prominent to a warmer temperature to bring them early into flower, a strong heat being undesirable as having a tendency to originate thrips.

HERBACEOUS CALCEOLARIAS.

To retard their flowering until May and June in the following year keep the plants as long as possible in the cold frame, their removal to a shelf in the cool house being essential only when the weather is so severe as to necessitate their being kept in the dark through protecting them from frost. Plants in a more advanced stage should be given their final shift into flowering pots, and their surroundings afterwards should be light, moist, and airy.

SCHIZANTHUS.

No matter of what variety the plants keep dwarf and grow more sturdily when they are given a position near the glass in a well ventilated and cool house. Stimulants are unnecessary until the pots are getting full of roots.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

WINTER CUCUMBERS.

DURING this month and the next it is not easy to keep a constant supply of fruits. The plants should be encouraged to grow as freely as possible. As soon as fresh roots appear on the surface give light and rich top-dressings of good fibrous loam, leaf-mould, and Mushroom-bed manure, the same temperature as the bed, with an occasional sprinkling of Thompson's Vine Manure. Do not allow the night temperature to fall below 65° on cold nights, and when severe weather prevails cover the pits at night with mats or other material. Give occasional waterings of tepid liquid manure, and a little air whenever it can be done with safety. Thin and regulate the growths and guard against over-cropping. If good pits are not at command preparations should be made for making up a hot-bed of fairly dry litter and leaves, about 5 feet deep and 4 feet wide. When the bottom-heat has declined to 90° place mounds of soil 4 feet apart and sow seeds in these; a little air should be admitted day and night. Seeds should also be sown of some approved variety in 3-inch pots to succeed the winter fruiters. Plunge the pots in a hot-bed of the temperature of 75° until the seedlings are through, when they should be placed in some position near the glass. These should be planted out when they have made three leaves, be grown in a moist atmosphere, and allowed to make free growth.

POT STRAWBERRIES.

The earliest plants which were recommended to be started last month are now beginning to grow. When they approach the flowering stage they should be moved to the lightest part of the house. Fertilise the flowers carefully at midday when dry with a soft camel-hair brush. This may not be necessary with strong trusses and later plants, but is best carried out with the earliest flowers. The night temperature should range from 50° to 55° at this stage, but not exceed the latter figure until the fruits are set. Fresh air is most important, and should be given on all favourable occasions, but avoid draught. Dry heat is most injurious, and moderate moisture should be afforded by damping and syringing. The roots must be kept moist but not too wet. One or two mild fumigations should be given before the plants come into flower. Succession plants should be introduced every fortnight, or according to accommodation and the demand. The plants must be forced slowly at the start and syringed carefully.

PLUMS AND CHERRIES.

The pruning and cleaning of these should be done. Very little pruning will be necessary if proper attention was given to pinching during growth.

Carefully wash the trees with two ounces of carbolic soft soap to the gallon of water, and top-dress the borders with good loam, lime rubble, and bone-meal, removing all the surface soil before top-dressing. Keep the house cool until forcing commences, which must be done most carefully and gradually.

Impney Gardens, Droitwich.

F. JORDAN.

ORCHIDS.

CATTLEYA TRIANE.

The buds are fast developing, so it is necessary to place the plants so that plenty of light may reach them. Plants that are flowering require more water than they have been receiving since the completion of growth. When the flowering season is over keep the plants drier again. The more dormant they can be kept till longer and brighter days are here the better.

C. quadricolor and *C. percivaliana*.—The same treatment as advised for *C. Triane* will meet the requirements of these. Flowering with the former they help to brighten up the houses during the dull month of January.

C. maxima is now passing out of flower, and will require scarcely any water at all till the early spring. Producing in November and December flowers of a pleasing shade of lilac, it deserves to be more widely grown.

CATTLEYA INTERMEDIA AND VARIETIES.

The new growths have now started, yet it is not advisable to water too freely. As soon as we get the turn of the year, when the supply of water may be increased to advantage, the growths will lengthen out rapidly and become much stronger and harder than if they were encouraged to grow at this season. Often they make two growths a year; in that case they do not rest after the flowering season is over, and those that have already made one growth since flowering last March and April will scarcely have begun to grow yet, so the same treatment applies. The growths that give the best flowers are those that are made in February and March; at that season growth is very quick, and the flower-buds appear often before the new pseudo-bulb is completed.

SOPHRONITIS GRANDIFLORA.

This charming cool house plant is now brightening its quarters with its brilliant flowers. Place them where full light reaches them. Little direct watering is required till the flowering season is over.

ODONTOGLOSSUM ROSSII AND O. CER-VANTESII.

These two dwarf species are now throwing up their welcome flowers; sufficient water is necessary to keep the compost just humid. They are best suited when suspended in the cool house where all light and sunshine may reach them.

THE ODONTOGLOSSUM HOUSE.

Many of the inmates of this house are now throwing up their flower-spikes. As soon as they are visible the question of whether it is advisable to let this or that plant flower should be decided, always bearing in mind that a weakly plant not only does not give characteristic flowers, but the ultimate growth will be retarded for some time; whereas by waiting till the completion of the next growth the plant would have recuperated and would then give better flowers. W. P. BOUND.

Gatton Park Gardens, Reigate.

KITCHEN GARDEN.

BROCCOLI.

The earliest varieties are turning in freely, and should be frequently inspected. Although there has been no severe cold yet to damage the plants the heads that are fit for use soon become blackened by frost. Let all those fit for use be lifted and

placed close together on a south border, or in some such sheltered position, where they can be easily covered with mats, straw, or Bracken. Snow's Winter White is the variety now fit for use, and this should keep up the supply until well through the first month of the New Year. In exposed and damp gardens the whole crop may have to be heeled over, but this is not generally necessary except in winters of exceptional severity.

CAULIFLOWER PLANTS IN FRAMES.

There must be no coddling of these, and if the smallest plants were chosen when placing them in their winter quarters they should still be dwarf and stocky. Give plenty of air on all occasions, except during very hard frost. Air should be left on the frames by night also. Damp will be the greatest enemy. Go carefully over the plants at intervals of a fortnight, removing all the decaying leaves and slightly stirring the soil. No water will be required during this and the coming month.

Frames containing Lettuce and Endive, from which supplies are being drawn, may be filled up

the house kept quite dark. Sprinkle the roots night and morning, and syringe the whole structure frequently.

Hopetoun House Gardens,

THOMAS HAY.

South Queensferry, N.B.

MISCELLANEOUS.

THE NEW SUCCULENT HOUSE, KEW.

DURING the past summer the last of the older public greenhouses, No. 5, built principally of wood, has been removed. Although a much more imposing structure, the new house is built on the same foundations with their length and width, the former 200 feet and the latter 30 feet. The chief differences in the new house are in height and much larger panes of glass. The old house was 15 feet in height, and by the addition of a lantern, 8 feet 6 inches in width,

THE NEW SUCCULENT HOUSE AT KEW.

again with plants from the borders. These two salads at this season are very liable to decay from damp, and should therefore be inspected very frequently. Admit air freely and remove the lights in dry, mild weather. Mustard and Cress must be sown almost weekly at this season. The boxes should be placed on a shelf near to the glass roof. Lettuces may also be sown thickly in boxes for cutting over. Roots of Parsley if carefully lifted may be put in boxes, and if placed in a warm house will soon augment the supply.

FORCING HOUSE.

Continue to keep up supplies of Rhubarb and Seakale. These will now after the frost force more freely. Seakale may be placed a few inches apart in the Mushroom house. The strong heat of the stove will be no longer required. All the roots that are intended for forcing should be got out of the ground without delay. They may be placed at the bottom of a wall and covered with leaves or stored in a frost-proof shed. See that a moist atmosphere is kept in the forcing house, and

running the whole length of the house, it is now 17 feet 6 inches in height. This will permit of much larger specimens being grown in the centre. The lantern will also allow of better ventilation. Built in 1855, the old house stood for fifty years, and in spite of this fact some of the wood—Mahogany, Pitch Pine, and Deal—was as sound as when the house was built. The framework of the new house is of iron, and the wood, with the exception of the sills, which are Oak, is Deal. Patent copper glazing has been used on the roof. In the "Tender Dicotyledon Hand-list of Plants" the following note in reference to the old house appears: "Not without its faults, for its direction being north and south, and the angle of the roof being low, the unnecessary massive iron girders prevent the rays of the sun freely reaching the plants. Notwithstanding this defect, which, owing to the increase of the London smoke, has become more obvious of late years, the contents of the house No. 5 are one of the most striking features at Kew."

As some of the plants require a warmer temperature than others, one half of the house is kept

5° to 10° warmer. Naturally the end nearest the heating apparatus is the warmer; with this and the ventilators a variation in temperature of from 5° to 10° is easily maintained, without a partition in the house to spoil the view from end to end. One of the principal features of the cool end are the Agaves, numbering over 130 species and varieties. The largest specimen is *A. atroviridis*, which is 10 feet through, and almost as much in height. Other interesting plants are *Dasylirocn acotrichum* 12 feet in height, also a smaller plant of the same species close by flowering at the present time; *D. quadrangulatum*, 10 feet high and 12 feet across; and *Beaucarnea recurvata*, 15 feet in height, with a peculiar swollen woody base. Planted out are two groups of *Protea cynaroides*, which were raised from seed in 1883. It is here also that the Date Plum (*Diospyros Kaki*) fruits annually. Several plants of *Pestudinaria elephantipes* (the Elephant's Foot or Tortoise Plant) attract considerable attention. The side stage on the east side is almost entirely filled with the natural order *Crassulaceae*. On the roof near the centre of the house is a large plant of *Cereus triangularis*, one of the night-flowering Cacti. The warm half of the house contains a more varied collection. Quite a large number of genera are represented, to say nothing of species; Aloes, over 100 species and varieties; *Gasterias*, *Cereus*, *Euphorbias*, *Opuntias*, *Phyllocactus*, &c. The illustration is from a photograph taken near the middle of the house looking along the east side of the warm end. In the foreground are several very fine specimens planted out in a rockery. The plant at the corner of the rockery almost in the centre of the illustration is the Turk's Cap Cactus (*Melocactus communis*), received from Antigua in 1902. A little to the left of this is *Echinocactus cylindricus*. The tall plant immediately behind is *Cereus giganteus*, received at Kew in 1895, when it weighed 4 cwt. The large plant in the left-hand bottom corner is *Echinocactus Gruesoni*. These are only a few of the gems of this most interesting house, often spoken of by the men who work or have worked in it as the chamber of horrors.

A. O.

THE BLACK CURRANT GALL-MITE

EXPERIMENTS have been carried out from time to time with a view to discovering a cure for the Currant Gall-mite infestation, which is dealt with in the Board's Leaflet No. 1. The subject has recently been investigated by Mr. W. E. Collinge, M.Sc., Lecturer in Zoology at the University of Birmingham. In 1901 Mr. Collinge sprayed some small bushes, which were badly infested, twice a week with a solution composed of: Sulphur, 2lb.; soft soap, 25lb.; water, 50 gallons. The sulphur was made into a gruel with water, the soap mixed with 5 gallons of boiling water, and the two mixtures added together and well stirred, after which sufficient water was slowly added to make 50 gallons. The results obtained were very encouraging, mites being found on fresh buds only on one bush in 1901. In 1902 no mites were discoverable on the bushes, but being near some infested bushes they were again sprayed. In 1903 they were still free of the mites, and also early in the present year no trees bore abnormal buds. The experiments were on a small scale, but it is proposed to continue them on a larger scale.

A small amount of success has also been obtained by hand-picking infested buds in small isolated plots, but it is strongly recommended that all infested stock should be burnt, and the utmost care should be taken only to replace them with cuttings after conclusive evidence that these are not infested. The Board will be glad to receive any information concerning experiments made with the spray mentioned above.

IMPORTATION OF PLANTS INTO CAPE COLONY.

NEW regulations as to the importation of trees, plants &c., into Cape Colony are gazetted under Proclamation No. 138, 1904 (Cape Colony), and are to take effect from September 1, 1904. These

regulations are substantially similar to those noted in the Board's Journal for September, 1903, page 260, but with some extensions. The importation of coniferous plants, or any portion thereof, with the exception of seed, is absolutely prohibited, as is also timber with the bark on, except scaffolding poles shipped from the Baltic or from Canada. Articles subject to these regulations introduced into the Colony by post will be intercepted and examined by an officer appointed for the purpose; and if found infested with any noxious insect or plant disease must be cleansed or destroyed. Ordinances have also recently been passed both in Southern Rhodesia and the Transvaal with a view to regulating the introduction of plants likely to disseminate insects.

In a memorandum* explanatory of these revised plant import regulations, the Cape Government Entomologist observes that the conditions in South Africa, more than in most parts of the world, justify drastic restrictions on plant imports as a means of minimising the introduction of fresh plant pests. It is a comparatively new country, from an agricultural standpoint, with sea connexion only with the rest of the civilised world. The oversea trade in living plants is still small, and there is no reason why the country cannot grow sufficient nursery stock of all kinds to keep pace with its requirements. Above all, the introduced pests of the orchard and vineyard are comparatively few in number, and some of the worst are still restricted in their occurrence. Cape Colony aspires to be a fruit and wine-exporting country, and therefore the exclusion of fresh pests is a matter of vital importance.

The general principle of the plant import regulations in the past has been the inspection of imports at the landing place, and their suitable treatment should they be found to be accompanied by any insect or plant disease "the introduction of which would be prejudicial to the interests of the Colony." Regulations based on this principle alone have, it is observed, a very grave weakness, which is the utter impracticability of adequately examining for insects, plant consignments of any size without subjecting them to ruinous treatment through exposure and delay; inspection, moreover, is no safeguard against most plant diseases.

These regulations have now been materially strengthened by the absolute prohibition of certain plants which are considered especially dangerous, and by restrictions on the importation of other kinds. The fumigation of all trees and woody plants is now required, and fumigation chambers are provided at the three principal ports. The fumigation is with hydrocyanic acid gas, and is a precautionary measure against inconspicuous scale insects.

WHITE ROT OF VINES.

THIS disease is due to the presence of a minute parasitic fungus called *Coniothyrium diplodiella*. On the Continent it attacks vines growing in the open air, and during recent years has frequently been met with on vines growing under glass in this country.

The fruit is the part most frequently attacked, and in severe cases the fungus spreads from the stalk of the bunch of fruit to the branch from which it springs; the foliage is unaffected. When once established, the disease spreads rapidly, and usually every Grape on a bunch becomes diseased, owing to the numerous minute spores of the fungus being conveyed by rain, syringing, &c., from diseased to healthy berries. During the first stage of disease the berries become pale brown in colour, and soon commence to shrivel, but do not fall. At a later stage, when the shrivelled berries have become dry, the skin is covered with minute whitish pimples representing the fruit of the fungus.

When the stalk of a diseased bunch is attacked, the fungus often passes on to the branch, where it forms slightly depressed areas, which are at first brownish in colour, but afterwards studded with the characteristic white pustules of fungus fruit. The diseased patches may extend for several inches

down one side, or the branch may be completely girdled by a zone of diseased tissue, and if this is the case that portion of the branch above the injured zone soon dies. In vineyards the disease is most injurious during seasons of great humidity accompanied by warmth. Under such conditions one-quarter to one-third of the crop may be destroyed within the space of a few hours.

The best remedy is to remove and burn all diseased bunches of fruit, and spray every part thoroughly once every five days with a rose-red solution of permanganate of potash.

If the disease is of recent origin and confined to the bunches of fruit, the above treatment will suffice. If, however, the disease has spread to the branches, its presence will be indicated by the slightly depressed whitish patches on the bark already mentioned. All such diseased branches should be cut out, as spraying will not check the disease on permanent parts of the vine.

BOOKS.

Proceedings of the Second Annual Meeting of the Chrysanthemum Society of America.—This interesting publication has only recently been issued, although it deals with the society's meeting in Chicago on November 13, 1903. For three years in succession the American society, following somewhat on the lines of the French National Chrysanthemum Society, has held a show and convention in conjunction with a local horticultural society, and apparently with most satisfactory results. Interest, which had been waning in the popular flower, has thus been revived, and the American growers have received considerable encouragement to continue their work. Mr. Herrington, the president, seems hopeful for the future, and his presidential addresses on each occasion proclaim him to be a zealous enthusiast for the advancement of the flower which has been the special care of his society. The volume recently issued is a creditable publication in every sense of the word, and somewhat similar in style to its predecessor. It contains an official list of all the varieties, American or foreign, known in the States, and has been compiled by the former secretary of the society, Mr. Elmer D. Smith, who is also the author a little pamphlet entitled "Smith's Chrysanthemum Manual," issued earlier in the year. It is some years since there was anything like an official American list of Chrysanthemums, and the present is certainly a welcome addition to the literature of the flower. There are two lists, one being confined to varieties; of American origin and the other to foreign varieties, the names both of raiser and importer are given, as also the date when introduced into America. The description is brief, being limited to section and colour. Of other matter there is President Herrington's address, delivered on the opening of the meeting, the reports of the secretary and the treasurer, a tabular statement of varieties submitted for certificates, and the text of a paper dealing with Chrysanthemum diseases, read by Professor Stone of Andover. A detailed list of the prizes awarded at the show is given, and the present leading officials are: President, A. Herrington; Vice-President, Elmer D. Smith; Treasurer, John N. May; Secretary, Fred. H. Lemon. This year the show was held in Boston, Mass., and it is to be hoped that by the introduction of new blood the society may, by considering the interest, not only of trade members, but also of the amateur element, of which there has hitherto been too little, grow and prosper and do a good work in the future, as it seems to give every promise of doing.

"Vegetables and their Cultivation."—After a careful perusal of this new publication, we have no other words than praise for the excellence of its contents. The author has dealt fully with the laying out of a vegetable garden, cropping, general management, pests and diseases, soils and manures, friends of the gardener, and, on the whole, is justly entitled to claim for

* *Agricultural Journal of Cape of Good Hope*, June, 1904.

* "Vegetables and their Cultivation." By T. W. Sanders, F.L.S. (W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C. Price 5s. net, by post 5s. 6d.).

his work "the most up-to-date and comprehensive on vegetables and their cultivation yet issued." Under the heading of "Soils" a long chapter is devoted to the consideration of the great variety of soils that are to be found in this country. Eighteen pages are devoted to manures, and under this heading invaluable advice is given. The art of cropping a vegetable garden is not forgotten, and in the pages that deal with this matter much useful information is disseminated. In the chapter devoted to "Miscellaneous Items" planting, watering, mulching, longevity of seeds, seedlings, thinning out, seed saving—this dealing briefly with each popular vegetable in alphabetical order—"bolting" of crops, tools, &c., preparing vegetables for exhibition, &c.; there is much good practical advice to those who wish to cultivate vegetables successfully. The consideration of "Pests and Diseases" takes up some fifty pages, and no pains have been spared to make this of service to the reader. Under the heading of "Crops: Their Pests and Diseases," the name of each vegetable is given in detail, as well as the pest or disease to which they are subject to attack. Diseases are similarly dealt with, and their effects illustrated by drawings and photographs. Popular vegetables are treated in a most interesting as well as in a practical manner. The botanical name of each is first given, this is followed by synonyms, foreign names, natural order, native habitat, duration, history, uses, and culture. In the case of the more important vegetables fuller particulars are given. For the guidance of the inexperienced cultivator twenty-two pages are devoted to a "select list of vegetables," the selections first having been submitted to several experts. For this reason they may be regarded as trustworthy. Not the least important feature of the new book is a series of tables showing when to sow or plant, when crops are ready for use, and the time they take to reach maturity, &c. This tabular arrangement of work to be carried out embraces all vegetables, so that the grower may see at a glance just the information he requires. "Some Garden Friends" is quite a novel idea, and the interesting way they are dealt with in the chapter allocated to them is commendable. In the last thirty pages is given a brief summary of a year's work in the garden. The volume is profusely illustrated, and there are five coloured plates of insect pests. For the student and the practical gardener there is little doubt this new book of Mr. Sanders' will be regarded as a standard work.

NURSERY GARDENS.

CHRYSANTHEMUMS AT FRAMFIELD, SUSSEX.

NO trade grower of the Chrysanthemum can claim to have done more for the flower than Mr. Norman Davis of Framfield, near Uckfield, Sussex. Not only has Mr. Davis distributed many of the best English-raised varieties now in commerce, but he has also raised many very fine seedlings. Several sports, too, from well-known varieties have emanated from this source, and not a season passes but that something interesting comes from Framfield. The new Japanese variety, Mrs. Charles Davis, is a lovely flower of a rich orange-yellow colour, and is a cross between J. R. Upton and Duchess of Sutherland. In many respects it is similar to the last named, and the blooms are strikingly effective. Another of Mr. Davis's seedlings is Marshal Oyama, a large, full Japanese flower of good substance, and with long, strap-like petals. The colour is bright chestnut on a golden-buff ground, and golden-yellow reverse. Of good quality also is the new Framfield seedling Algernon Davis. This is a massive bloom, with petals of medium width that twist and curl prettily, the colour rich bronze, shaded chestnut. Japanese novelties raised by Mr. Charles Penford, as usual, are a goodly set, and these Mr. Davis is to distribute in early spring. The present series promises to well maintain that high distinction. Leigh Park Rival is an orange-yellow, shaded

bronze, having very long petals, and this variety has been certificated this season. Miss Mona Davis is another variety that has received similar honours. This is a lovely creamy white flower, with broad, drooping florets, and from a second crown bud selection should be welcome for the November shows. Another flower that has been much admired is Lady Curzon. It is a bloom of good quality, not so large as some perhaps, but quite large enough all the same. The colour is a rich canary yellow, faintly tinted chestnut. A fine crimson Japanese of large size is George Hutchinson. The florets open flat, and finally droop, making a useful exhibition flower. Duchess of Bedford is another exhibition bloom something in the way of the well-known Mrs. C. Beckett, but the petals are rather longer. This new sort may be regarded as a good white. A very large incurved Japanese is Miss Fitzwygram, which is suitable for the back rows of a show board, the colour golden-yellow. Mont Blanc might well be regarded as an incurved, as the late flowers show this character. The colour is ivory-white. Of the more popular up-to-date Japanese sorts Mr. Davis has a very fine selection. Striking examples are such sorts as Mrs. C. Beckett, Beauty of Leigh, Henry II., Valerie Greenham, Mrs. J. Hadaway, Mrs. J. Dunn, Maud du Cros, yellow Mme. Nagelmackers, J. H. Silsbury, Mlle. Albertine Bertrand, and The Pearl. An immense flower with long, spreading florets is Mrs. Guy Paget. The flowers are flushed with pink, changing to ivory-white as they develop. When propagated early, second crown buds should be retained; a later striking, first crown buds. The blooms of Mary West are large and massive, and their colour yellow, shaded reddish bronze, makes them attractive.

M. E. Calvat's introductions of the present season are much better than they have been for some years past. Several in the present set seem likely to occupy prominent positions in succeeding seasons. The more conspicuous sorts are Roi d'Italie, a canary yellow flower, with a deeper reverse, making a capital Japanese bloom. Mme. B. Oberthur is another fine sort, pure white. Chrysanthemiste Montigny is good here, and has been shown well in two or three instances this season. It is an incurved Japanese bloom, colour pale straw yellow, slightly flushed red. Mlle. Anna Debono is another pure white Japanese, and Princess Mafalda is also pure white, with an attractive tinge of green in the centre of the bloom. Maurice Rivoire, deep red, with golden reverse, and Préfet Boucourt, creamy white, delicately flushed rosy salmon, are both worthy of notice and distinctly good. Established favourites are well grown here, and in large numbers.

New incurved varieties have given quite a fillip to this type of the flower this season. The novelties of the present year are devoid of coarseness, yet they are large and of beautiful globular build. Mr. Davis has cultivated them well, and among the most striking examples we are pleased to mention Amber Beauty. This is a Framfield seedling and is a splendid incurved of true type, without the least trace of Japanese character about it; colour, clear shade of orange amber. Other good incurved sorts are Buttercup, a large flower of good form, rich buttercup yellow; Mrs. J. P. Bryce, pure white; Margaret Brown, purple-lilac, with silvery reverse, fairly large size, and of good form; Hilda George, a large bloom of good form and of a silvery mauve colour. The two last named were raised by Mr. W. Seward, both being certificated this season.

Other new incurved sorts worthy of notice are: Mark Tonrie, rosy amaranth, and Triomphe de Montbrun, a handsome flower, inside of florets rosy crimson, with light buff reverse. Considerable attention is given to the culture of so-called decorative Chrysanthemums, Mr. Davis persistently testing exhibition and other sorts with the object of ascertaining if any are really suitable for growing for market and for cut flowers. He has often found that a variety, rather undersized for exhibition, will develop plants carrying a quantity of dainty flowers for decoration. Of the early-flowering and semi-early flowering varieties—that Mr. Davis prefers to describe as "Hardy Garden" Chrysanthemums—there is quite a representative collection.

To the older varieties is added a plethora of dainty novelties. These newer sorts embrace a very fine lot of Japanese flowers, the plants, in many instances, being of branching and robust growth. Specially good new sorts are the following: Champ d'Or, yellow; Etoile d'Or, brilliant yellow; Howard H. Crane, chestnut, golden reverse; James Bateman, a Framfield seedling, white, heavily shaded pink; Jason, pale yellow; Fleure Rouge, reddish salmon; Etoile Blanche, starry white flowers; Enchantress, bronze, shaded salmon; Acajou, reddish mahogany; Glacier, pure white; Nina Blick, bright reddish bronze; Kitty, pink; Pride of Hayes, soft rose; Rosie, terra-cotta; Rubis, bright purple-amaranth; Madge Blick, rich amaranth; Mlle. Lucie Daveau, purest white; Mrs. W. Hubert, salmon-rose; and Pride of Keston, deep rose, silvery reverse. The glass houses at Framfield are numerous. The big house covers just half an acre, and measures 325 feet by 62 feet. We know of no other glass house to equal this for Chrysanthemum displays. It has a double span, and in the spring is filled with early vegetables, Peas, &c. These crops are generally followed with Tomatoes. In August last it was planted with some 10,000 Chrysanthemums, representing all the types, except the earliest, which, of course, are grown outdoors. The beds of singles—both large and small-flowered sorts—Pompons, Anemone-Pompons, and all the big Japanese varieties, made a remarkable display. They were all grown in bush form, and many were the surprises as to the possibilities of using the large-flowered sorts for decorative purposes when freely grown.

SOCIETIES.

NATIONAL ROSE SOCIETY.

REPORT OF THE COMMITTEE FOR 1904.

THE report which the committee have now the pleasure of presenting must, in their opinion, be regarded as the most favourable that has yet been placed before the members, for there is not a single branch of the work undertaken by the society which does not show during the past year a distinct advance.

The Metropolitan exhibition, which again took place, by the kind permission of the Benchers, in the Temple Gardens, was one of the largest, and certainly the most varied and interesting, the society has yet held, while the average quality of the exhibits was at the same time exceptionally good. In fact, considered as a whole, it may justly claim to have been the finest Rose show ever held in any part of the world. The weather previous to the exhibition was, throughout a great part of the country, very favourable, while the fixture, July 6, proved singularly well-timed, bearing in mind that during June and the early part of July the season was a somewhat backward one. The arrangements connected with the show were, on the whole, very satisfactory. This was in a great measure due to the experienced staff of the Royal Horticultural Society having been again so generously placed at the disposal of the committee on the show day by the president and council of that society.

In order to maintain the general interest in this, the leading Rose show of the year, several new features are annually introduced. These appear to have been much appreciated, especially by the visitors, who were more numerous than at either of the two previous exhibitions held by the society in the Temple Gardens.

Although a provincial show was not held this year in the north of England, no break was allowed to take place in the long series of interesting competitions for the society's two Jubilee challenge trophies, which were, with the consent of the committee, competed for instead at the Bath Rose Show on July 14. It had often been proposed that the committee should hold an exhibition in September, in order to bring before the public the large number of Roses now in cultivation which bloom freely in the autumn, but not until the present year has this been found practicable. For a first venture the autumn Rose show held by the society, in conjunction with the Royal Horticultural Society in their new hall in Vincent Square, in September last has been generally considered a great success. The committee are encouraged to think that, when better known, this very interesting and instructive exhibition will fully justify the new departure in the way of Rose shows that has now been made. It may here be mentioned, as showing the friendly feeling existing between the two societies, that on the occasion of the opening in July last of the magnificent hall, where the autumn Rose show was afterwards held, a congratulatory address was presented from the National Rose Society to His Majesty the King as patron of the Royal Horticultural Society, in reply to which address an equally cordial message has since been received, signed by the president, treasurer, and secretary of the Royal Horticultural Society.

It is with the deepest sorrow that the committee have to record the sad loss the society has sustained in the death of their president, the late Dean of Rochester, which took place on August 27 last. It may not be generally known that Dean Hole presided at that memorable meeting of rosarians in 1876 when the National Rose Society was founded. He was

at once elected president, a position he occupied with great benefit to the society for twenty-seven years. The loss of Dean Hole to the society is in many ways an irreplaceable one, for he occupied an altogether unique position in the Rose world, as being the great apostle of Rose culture, so that wherever Roses are mentioned the name of Dean Hole must long remain inseparably connected with them. It is proposed early next year to set on foot a fund in order to establish a suitable memorial to the society's late president, to which kind many of the members will no doubt be glad to contribute.

The committee also announce with much regret the recent death of the Rev. A. Foster-Melliar, one of the society's most valued vice-presidents. He had just completed the revision of a new edition of his "Book of the Rose," one of the most complete and practical works on Rose culture, particularly from an exhibitor's point of view, that has yet been written. He was himself a keen exhibitor, and in 1893 won the society's Tea and Noisette challenge trophy. His kindly presence will be much missed, both at the annual meetings and at the exhibitions.

The bye-laws and regulations of the society have year by year received various additions and amendments, but the committee feel that the time has now come when those additions and amendments should be brought into line, and the whole series overhauled. The constitution, rules, bye-laws, and regulations have been drawn up with much thought and care by Mr. C. E. Shea, assisted by a small committee of experts in such matters.

Another sub-committee, which has also been doing good work during the past year, has been that appointed to prepare the society's new work on pruning Roses, which is designed to meet a want long felt by rosarians generally. In referring to that sub-committee special mention must be made of the great assistance it has received in its somewhat difficult task from the excellent reports sent in by one of its members—Mr. G. L. Paul.

FINANCE.

The receipts in gate money at the Temple Rose show exceeded those at the previous exhibition by nearly £100. This advance, together with the large amount received in subscriptions from new members, has placed the finances of the society in a most encouraging position. The receipts from all sources, including a balance from the previous year of £53 7s., amounted to £1,383 19s. 3d., and the expenditure to £1,064 19s. 4d., leaving a balance in the treasurer's hands of £319 19s. 11d. Of that amount it is proposed to set apart £100 for the new reserve fund, and to contribute £25 to the new Horticultural Hall Fund of the Royal Horticultural Society. The advance in membership is most gratifying as showing the increased interest now taken in the work of the society in fostering, by its exhibitions and publications, the cultivation of the Rose in all parts of the United Kingdom. During the past year 379 new members have joined the society, or a greater number than in any previous year. In fact, the number of members is at the present time more than double what it was only four years ago, the totals being 584 in 1900, and 1,208 in 1904.

ARRANGEMENTS FOR 1905.

As the Benchers object to the metropolitan show of the society being held any longer in the Inner Temple Gardens, the committee have entered into arrangements with the Royal Botanic Society of London to hold that exhibition in their gardens in Regent's Park on Thursday, July 6. The Royal Botanic Gardens may not be quite as centrally situated as the Temple Gardens, but in all other respects they are much better adapted for a Rose show. In fact, they may be regarded as forming an ideal spot in which to hold such an exhibition. Added to this, for the first time in the society's existence, the committee will have an entirely free hand in all the arrangements connected with their metropolitan show, which cannot but prove a great advantage to both exhibitors and visitors. The provincial exhibition will be held on July 18 at Gloucester, in conjunction with the Gloucester Rose Society.

The autumn Rose show will again be held in the Royal Horticultural Hall in Vincent Square, in conjunction with the Royal Horticultural Society, and next year at a rather later date, viz., Tuesday and Wednesday, September 26 and 27. This exhibition will be rendered even more attractive than the last by the introduction of several new classes in order to illustrate still further the value of the Rose as an autumn flower.

To the donors of special prizes the committee tenders their best thanks, as these prizes not only add considerably to the interest of the society's exhibitions, but also allow of the money thus saved being spent on the improvement of other classes. The local secretaries have once more obtained for the society a good many new members. Among the most successful may be mentioned Mr. C. Barber, Mr. E. J. Holland, Mr. H. E. Molyneux, Rev. J. H. Pemberton, and Mr. E. R. Smith. To Miss Willmott, one of the society's vice-patronesses, the thanks of the committee are especially due, not only for the large number of members she has obtained, but also for the kind interest she has taken in the work of the society generally, and her earnest endeavours at all times to advance its interests.

READING GARDENERS' ASSOCIATION.

At the last meeting of the above society, which was largely attended, Mr. T. J. Powell, Park Place Gardens, Henley-on-Thames, gave one of his well-known practical demonstrations. Having already treated upon bouquet-making, sprays and buttonholes, and the decoration of vases with flowers, Mr. Powell, by request, gave an object-lesson in packing fruit for transit. In drawing the members' attention to the system he practised, he said that he should put before them the ways he had found were the best for his particular purpose, which perhaps, however, would not prove to be suitable for all present. Strawberries were first touched upon, and were followed by Red Currants, and, although so late in the year, a splendid lot of fruit of the latter, picked from trees in the open on the 3rd inst., had been brought by

Mr. F. Bright, Whiteknights. Grapes, the most popular of fruits for sending to friends, &c., were packed in baskets by themselves, and also with Melons and Peaches, Citrons and Apples being used to represent the latter. Peaches alone, Apples, Pears, and, in fact, all English fruits were dealt with. Particular attention was directed to the proper labelling of baskets, &c., and that care should be taken that everything was done to ensure the better handling of the packages by those who came between the sender and receiver. Needless to say very great interest was manifested in the demonstration, and many questions were asked during the evening. As before mentioned, Mr. Bright provided Red Currants, and Mr. W. Townsend two splendid bunches of Grapes. A hearty vote of thanks was accorded to Mr. Powell for his demonstration, on the proposition of Mr. C. Foster, supported by Messrs. Neve, Townsend, and Exler.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 5, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

The Bullace (M. M. W.).—The Bullace grows in the hedgerows in many parts of England, and the best way to raise a stock would be to sow half a bushel or so of its fruits in nursery lines. It is not uncommon in old orchards, but we suppose the Damson supplanted it in most places, just as the Apple and the Pear did the Service Tree. The Sloe is confined to Europe, but the Bullace extends to (or from) the Himalaya and North Africa. We should think the Mirabelle race or the Cherry Plums are cultivated descendants of the Bullace.

Rose cuttings after frost (E. M. JARVIS).—Many deaths occur among cuttings of Roses when planted in the borders in autumn, from the lifting power of the frost loosening the soil and letting the air in around the base when the wound is healing, and forming a callus preparatory to the emission of roots. This might be obviated by placing a mulch of old leaf-mould between the rows as soon as the cuttings are planted. When the mulch has been omitted, the soil should be made firm around the cuttings after a frost as soon as the surface gets dry enough to tread upon without sealing it up too much. The mulch can then be added and all will be safe.

Golden Irish Yew (WHITTY).—There are two or three variegated forms of the Irish Yew, but one recently noted under the name of fastigiata aurea is certainly the best that we have seen. In this the variegation is not limited to a few shoots, as is the case with some kinds. It certainly forms a very bright and effective specimen, and is worthy of association with the golden forms of the common Yew. Another very distinct golden Yew is that known as horizontalis elegantissima, a very free-growing variety of the common Yew, and which forms a strong leading shoot, and pushes out the stout side branches in an almost horizontal manner.

Holly hedgerows (S. S. TYNDALL).—For hedgerows no other plant is scarcely so well adapted. It forms in course of time a fence as tall, as wide, and as dense as can well be wished for by the most exacting. But it is of slow growth in a young state; when it has been planted three or four years, if the requisite attention be given to it, the advance is more rapid. There are several instances of enormous Holly hedges about the country. That planted by Evelyn at Say's Court, prompted thereto, it is said, by the Czar Peter when learning shipbuilding at Deptford Dockyard, although he is credited by some with having destroyed it, has an historical reputation. Scotland is famous for its Holly hedges. There is one at Tynninghame, the Earl of Haddington's seat in Scotland, which is said to be 150 years old, and which is both broad and tall. There is a very large and broad hedge at Keele Hall, Staffordshire, and it affords a resting-place in winter for hundreds of birds.

Raising conifers from seed (WALLIS J. WHITTON).—In raising the different hardy conifers from seed, the treatment given them will depend to a great extent upon the quantity of seed it is intended to sow, for where large quantities of plants are raised, the seed of many kinds is sown in the open ground, and generally a sheltered border is chosen for the purpose. But with small quantities of seeds, or in the case of choice or delicate kinds, by far the better way, and that usually followed, is to sow them in pans or boxes, which are protected by a frame during the earlier stages of the young plants. In the case of seeds that are to be sown in the open border, the general way is to prepare the soil for their reception by raking it to a fine and even surface. On this the seed is sown, gently patted down with the back of the spade, and then covered with some finely-sifted soil. The depth at which the seeds are covered will depend upon their size. For the smallest a quarter of an inch will be sufficient; while in the case of the large kinds an inch is not too much. The soil prepared for covering the seeds should be of an open, sandy nature, and it is an advantage if some charcoal dust is mixed with it, as this tends to prevent the young seedlings damping off. If there is none at hand wood ashes are a good substitute. The best time to sow seeds in the open ground is about April, as the soil will then have been nicely pulverised by the winter's

frost and just in condition for seed sowing. Besides this, there is all the growing season before the young plants, which pass through their most critical stage before the winter. When the seed is sown, a few Spruce branches laid over the bed will be of service to prevent too rapid an evaporation, and thereby assist the germination of the seeds.

Planting street trees (NORTHERNER).—It is a common practice in planting shade trees along the borders of streets to remove nearly all the tops by a single cut across the stem, converting the trees into blunt-headed poles, the object being to reduce the mass of leaves which the mutilated roots must support and to lessen the action of winds. The operation is usually successful, but it is a long time before such trees attain a handsome or symmetrical form. A much better way, after having secured a copious supply of roots by careful digging, is not to cut off any large limbs (unless to give the head a good form), but to thin out all thick, small branches and shoots, leaving only a few evenly distributed, and cutting partly back all that remain for reducing the amount of leaves. In this way we retain the form and size of the head to a greater or less degree, with little draft on the shortened roots, and little chance for the winds to affect the trees.

Culture of Epiphyllums (BERKS.).—*E. truncatum* can be had in flower at any time during the winter, provided the plants have had their growth well matured and they are put in heat long enough before they are required to be in bloom. In most cases about the end of January or the beginning of February will be early enough to have them in, as flowers are then scarcer than at other times. Where there is a sufficient stock it will be well to start them at three or four different times, allowing about three weeks to intervene between each set of plants being put into heat. A portion may now be started. A cool stove temperature will be best. The flowers of Epiphyllums generally, including the truncatum varieties, are naturally short lived, and when the plants are kept very warm whilst being brought into bloom, it makes them so soft in texture that they do not keep fresh long in a cut state. To correct as far as possible the fugacious nature of the flowers and to make them stand well in water, the plants should be stood well up to the light whilst the bloom is coming on. No more atmospheric moisture than necessary to keep the air in a genial condition should be used. Be careful not to make the soil too wet, especially before the roots have had time to move. Whether on their own roots or grafted on the Pereskia, Epiphyllums dislike the soil being too wet.

PUBLICATIONS RECEIVED.

Rotting of Potatoes During Storage, published by the University of Leeds; The Protection of Native Plants, by Robert Tracy Jackson, Cambridge, Mass.; Catalogue of Books on Gardening in Cardiff Public Libraries; Journal of the Board of Agriculture; Kew Bulletin of Miscellaneous Information, containing the list of seeds of hardy herbaceous plants and of trees and shrubs; Boletim da Real Sociedade Nacional de Horticulura de Portugal.

CATALOGUES RECEIVED.

Gladioli.—Messrs. Kelway and Son, Langport, Somerset. *New Carnations and Chrysanthemums*.—Messrs. James Veitch and Sons, Limited, Chelsea. *Seeds*.—Messrs. Sutton and Sons, Reading; James Carter and Co., High Holborn, W.C.; Frederick Roemer, Quedlinburg, Germany. *Chrysanthemums*.—Mr. Frank Lilley, Guernsey. *Spring Seed Guide*.—William Fell and Co., Limited, Hexham.

TRADE NOTES.

GARDENING CATALOGUES.

THE Amateur Guide in Horticulture for 1905, published by Messrs. Sutton and Sons, Reading, contains a mass of information that will well repay reading and digesting by all interested in gardening. The flower lover, the fruit and vegetable grower, will find descriptions and illustrations of the best things to grow, as well as notes upon their culture. This annual publication is as beautiful as it is useful. The illustrations are finely reproduced, the soft half tones of leaves and flowers being faithfully shown.

The chief features of the Practical Gardening Annual issued by Messrs. Carter and Co., High Holborn, are the beautiful coloured plates of flowers. These are reproductions of coloured photographs, and are extremely good; the colours are not exaggerated, and the dwarf Peas and Primulas are, we think, particularly good. This publication has an appendix containing monthly operations for all departments of the garden. Readers will there find many valuable hints about the culture of flowers and vegetables.

MESSRS. PEED AND SON'S NEW NURSERIES.

MESSRS. JOHN PEED AND SON write: "We beg to inform you that we have taken new nursery ground at Morden, Surrey, where we shall grow our fruit trees, Roses, and shrubs. Our addresses are now, therefore: Rouppell Park Nurseries, West Norwood, S.E.; Streatham Park Nurseries, Streatham, S.W.; and Morden Park Nurseries, Morden, Surrey."

GARDENING APPOINTMENT.

MR. H. HOWELL, late head gardener at Binfield Manor, Bracknell, for eighteen years, has been appointed gardener and estate manager to C. Kaufman, Esq., The Wilderness, Earley, Reading.

* * The Yearly Subscription to THE GARDEN is: *Inland*, 25s.; *Foreign*, 17s. 6d.

THE GARDEN

No. 1728.—VOL. LXVI.

DECEMBER 31, 1904.

HORTICULTURE IN 1904.

WITH the present number of THE GARDEN another year draws to a close, and a year, it may be said, full of incident in the world of horticulture. The most memorable celebration was the hundredth anniversary of the formation of the Royal Horticultural Society, which was fortunate in marking so auspicious an epoch by the opening of a new hall in Vincent Square by his Majesty the King. With this central meeting place for trade and amateur growers, and the new garden at Wisley, the society is enabled to increase its work for horticulture in this country, and a work, let it not be forgotten, entirely without State support. The council wish it to be remembered that a large debt still exists. During the year many beautiful and interesting exhibitions have been held in this hall, and the most important were the displays of fruit, Colonial produce, and autumn Roses, in conjunction with the National Rose Society.

This vigorous society is fortunate in possessing a president who is devoted to its interests, an untiring secretary in Mr. Wilks, and a strong council. Without this combination the extraordinary development of recent years could not have taken place, and the increasing roll of fellowship is the result of giving plenty for the money, in the shape of fortnightly meetings, exhibitions in the Temple Gardens and at Holland Park, and a journal which has taken its place among the most prized of horticultural and scientific productions. It contains the usual proceedings of the society, and a full report of the invaluable lectures delivered during the year at the fortnightly meetings.

The National Rose Society has a happy record for the year, and this was mentioned so recently that further reference to it is unnecessary. Next year the great summer metropolitan show will take place in the gardens of the Royal Botanic Society at Regent's Park, and the experiment will be watched with interest and not without some anxiety. But the authorities have met the Rose Society in so generous a spirit that serious failure, given the blessing of a fine day, is almost impossible.

The Royal Botanic Society is making a determined effort to bring back its former influence and glory. Its botanical work should ensure the sympathy of scientists, and we wish it well in the future.

It is pleasant to record, although we are not in entire agreement with the multiplication of special societies, that there is vigorous life in those devoted to the Chrysanthemum, Potato, Sweet Pea, and Daffodil. The interesting discussion that has taken place of late in our pages relating to the poor quality of many varieties of Potato will be, we hope, fruitful in good results. Exhibitions should be conducted on a broad basis. Quality is as precious as quantity, and size and crop are not the only virtues that a vegetable should possess.

The Horticultural Exhibition at St. Louis, and the Old English Garden designed by Mr. Goldring and carried out with much skill by Mr. T. W. Brown, brought credit to the British horticulturists who showed there. The Dusseldorf Exhibition was also of much interest.

It is gratifying to notice the foundation of many new gardening improvement societies for young gardeners, and the older branches have greatly increased their membership. This is satisfactory. It shows that horticultural practice is spreading, and that there is a desire for knowledge on the part of those engaged in the work. This reminds us of Mr. Watson's earnest endeavours to place the British Gardeners' Association on a sure foundation, and we hope his efforts will be crowned with success.

The past year will be remembered for a beautiful summer and a golden autumn. A fine fruit crop after a brilliant promise, which was unfulfilled partly through a plague of insect pests, the glorious colouring in wood and garden in October, and a rainy and foggy December are the chief garden features of 1904. The year is remarkable for the excellence of the vegetable crops.

Our gardening charities, in spite of slackness in trade, have substantially increased their revenues, and this is especially true of the Gardeners' Royal Benevolent Institution, a record subscription having been made through the effort of the chairman, Mr. H. J. Veitch, and a munificent donation of £500 from Mr. N. N. Sherwood, who also contributed the same sum to the Gardeners' Orphan Fund.

The proceedings of the Horticultural Club have been marked by two papers of exceptional interest, one by Sir John Llewelyn, Bart., on "Himalayan Rhododendrons," and the other by Sir George Watt on "Indian Primulas." Both of these will be published in pamphlet form by the committee of the club and in the Royal Horticultural Society's Journal.

The retirement of Professor Henslow from the honorary secretaryship of the Scientific Committee of the Royal Horticultural Society after twenty-five years service should not be passed by unnoticed.

A brief record of the principal events of the year brings the sad duty of naming the men who have passed into silence. Horticulture has lost many devoted servants during the past year, some that had long passed the allotted span of life, and others removed in the full enjoyment of their life's work. We think of the stately figure of a noble churchman and gardener in the Dean of Rochester, of the Rev. Wolley-Dod, of the cheery presence of the Rev. Foster-Melliar, of Mr. F. G. Lloyd, a member of the Council of the Royal Horticultural Society; of that ardent Auricula grower, Mr. Richard Gorton; and among nurserymen of Mr. Herbst; Mr. Hugh Fraser, of Leith; Mr. John Jefferies, Cirencester; Mr. Hugh Dickson, Belfast; Mr. Thomas Smith, senr., Stranraer; Mr. David Drummond, Dublin; and Mr. William Cole, Feltham. Gardeners mourn the loss of Mr. G. T. Miles, gardener and agent to the Earl of Carrington, at High Wycombe, and Mr. Edwin Hill, gardener to Lord Rothschild, Tring Park. These are only a few of the leading figures in the horticultural world that have ceased their earthly toil, and their good work for gardening should be an example to a younger generation.

May the year that is dawning bring health, happiness, and prosperity to all our readers. It is to their practical help we look in the future, and we are happy in the belief that it will not be denied.

THE CHILD'S GARDEN.

CHILDREN can be taught to garden at a very early age. I hardly remember when I began, but I know that greatly to my delight I was constantly taken away from my lessons by my mother to help her in her lovely garden, for she discovered that out of three sisters I was the one who showed the most aptitude for that entralling occupation. We had all little gardens, but mine was always "a-growing and a-blowing," while the other two were neglected wildernesses of weeds, so much so that the master confiscated them until the promises of amendment were carried out. How well I remember my dear little plot edged round with bits of Derby spar, and centred by a Geant de Bataille Rose, the joy and pride of my young heart, and backed by a hedge of old-fashioned Sweet Peas. It was bright with annuals, bought by pennies hardly earned by picking

up Acorns for the deer, and when the season came for bedding out there was the timid begging from the somewhat obdurate Lancashire gardener of a few surplus Geraniums, Heliotropes, and Calceolarias. Oh! the joy of wheeling those treasures off in the little green wheelbarrow and planting them. Then later came the first nosegay for mother, arranged with more generosity than taste, and placed on her dressing table as a surprise. I am sure the love of gardening is inborn, and I do not believe it can be instilled, but circumstances will develop it if it be there. There is a mysterious sympathy between the born gardener and his flowers—he knows what they want by instinct, or if he is not quite sure he finds out—he treats them, in fact, as a mother does her children. The boy is the father of the gardener, and it is most interesting to train and help the gardening faculty to develop. Children should always have a corner, an outdoor nursery as well as an indoor. Never mind if your gardener grumbles, and complains that they tread mud into his paths, and worry his life out for pots and soil and seeds, be quite firm about it and insist on the children's garden.

I remember a little girl of six years old whose father was the owner of a beautiful garden of world-wide repute—a garden faultlessly, icily regular, splendidly null—saying to me, pathetically, "I do so want a little garden of mine own with real flowers like what you have." The prim flower-beds, the trim borders, the acres of glass houses, meant nothing to her. Her little true soul was yearning for a patch of garden where she could dig and rake and sow seeds. She wanted a green wheelbarrow and a red watering can, and, above all, real flowers that she could touch with her little hands unchided. She got all these delightful things ultimately, and her father's gold having melted in some adverse blast of fortune's furnace, she is now earning more than a modest competence from her flowers, and, better still, doing good work in her generation. The tiny sower of Mustard and Cress may become a great light in the horticultural world, and the child's garden may grow into a paradise of cultured beauty. Therefore give your children gardens when they ask you, and await results.

The children's garden is too often relegated to a bit of waste land in some unneeded portion of their parents' property, on the plea that anything is good enough. This is wrong; for good beginnings make good endings. It should be, no doubt, placed where its position should be tenable, for the little workers certainly do not always maintain their property in the immaculate state of tidiness desirable in the eyes of the high-class gardener. Some pleasant spot in the kitchen garden should be selected, sheltered, but airy, with a modicum of shade; and each child should have its plot—quite a small one—and a little well-made gravel path should run round each section, which should also be edged with stones or tiles. Bricks make a good edging, and prevent the soil from falling out. Before the child is given plants it should be allowed to expend some of its energies in digging, and should be given a good set of tools, not the rubbish that generally passes as a set of child's gardening tools, which are a source of danger and disappointment, but a strong, well made small iron spade, a shallow rake and a hoe, a trowel, and a truck basket, all marked with the child's initials to avoid dispute. A small iron wheelbarrow is most serviceable, and a gallon watering can. If possible a barrel for water should be near the allotment, with an easy tap, and a tub beneath it to catch the water against very

probable accidents—such as leaving the tap running. The children should have, if possible, a little shed of their own to keep things in, so as to avoid running foul of the gardener, for "they bothering children" are very often terribly in the way. It is very wise to start a child at once in the right road, so first teach him to hold a spade properly, then to trench a little, and rake and hoe; to rake is, after all, the most difficult art. After a lesson or two the child will be able to sow seeds quite nicely, patting down the soil and smoothing it with his small hands. He must also be taught to mark the talleys neatly with name of the flower, and to watch for the appearance of the little plants. It is best, before the child can discriminate the difference between these and weeds, to sow the seeds in chequers or lines, or make them put twigs outside a circle marked out with a flower-pot. Teach them to be economical with their penny packets, sowing thinly, for wasteful sowing is a common fault with their elders. AUGUSTA DE LACY LACY.

(To be continued.)

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 3, Southampton Street, Strand, London.

CLIANTHUS PUNICEUS OUT OF DOORS AT CHRISTMAS.

From Kingswear, South Devon, Mr. S. W. Fitzherbert sends for the third year in succession the curious bright red flowers of *Clanthus puniceus* (the Glory Pea), gathered at Christmas from an open, unprotected wall.

A FREAK IN GRAPES.

Mr. E. R. Whitwell sends a monster Grape that is very unusual and interesting. We have never seen one like it before, but Dr. Masters, our great authority on these freaks of Nature, in his well-known work "Vegetable Teratology," says: "In the Barbarossa Grape I have frequently seen a fusion of two, three, four, or more berries quite at the end of the bunch, so that the clusters were terminated by a compound Grape." Mr. Saunders writes: "I have not been able to make out to my satisfaction how many Grapes have united together to form your monster, but I believe seven have. I cut the fruit through horizontally, but could not find any septa or divisions in it; there were only four pips. A malformation of a somewhat similar character may often be seen in the terminal blossoms of the common Foxglove, in which case several flowers have united to form one large campanulate flower."

NOTES OF THE WEEK.

FORTHCOMING EVENTS.

January 2, 1905.—Meeting of the Mansfield Horticultural Society.

January 3.—Royal Horticultural Society's meeting; meetings of the Redhill, Reigate and District, and the Sevenoaks Gardening Societies.

January 11.—Sheffield Chrysanthemum Society's meeting.

January 17.—Meetings of Reigate and Sevenoaks Gardening Societies.

Horticultural Society of Africa.

A large, representative, and influential meeting of gentlemen from the principal centres of the Transvaal interested in horticulture assembled at the Grand National Hotel in September. The object was to form a horticultural society for the Transvaal, which should be part of the larger society embracing the whole of Africa. Already the movement has been initiated, with every prospect of success, in the Cape Colony and Natal. It is proposed that each colony should have a separate organisation, with its own president, secretary, and council. The whole movement, so important in its future developments and possibilities, has been originated by Mr. Alfred Chandler, F.R.H.S. Eog., F.R. Met. Soc. He has written several letters to the local Press on the subject, with the result of inspiring horticulturists of all classes with enthusiasm for the project. The chairman moved that a society should be formed under the name of the Horticultural Society of Africa (Transvaal, Orange River Colony, and Rhodesia section), with the addition of the prefix Royal when a Charter had been obtained.

BLUSH MALMAISON CARNATION.

Mr. Sturm suggested the insertion of the word British in the designation of the society. The chairman, however, pointed out that it would be beneficial and desirable to have members and subscribers from citizens of other countries, and thought that the membership of the society should not be confined to those of British nationality. This view was supported by Messrs. Barrel and Menzel. Mr. Sturm then withdrew his suggestion.

Carnation Blush Malmaison.—Although of late years there have been several new varieties of Malmaison Carnations introduced, many growers still cling to the old ones. Among these the Blush Souvenir de la Malmaison is one of the best. It is the parent of several sports, the best of them being The Pink and the Princess of Wales. There is also a crimson variety.—T.

Roses in India.—There can be no question that Roses of all kinds thrive and bloom to perfection in India. In Upper India and in our hill-stations, whether Himalayan or the other ranges, Roses find a congenial home, and bloom to perfection. Even in Lower Bengal these lovely flowers can be brought to produce very fine blooms, but they require more care and attention and more cultivation. We demonstrated in

January, 1900, at our Rose show, what could be done, so that no one—even in smoky and foggy Calcutta—need despair of growing Roses successfully. Nearly every family of the Rose can be grown to perfection in upper India, except perhaps the Moss Rose, and this has been successfully cultivated on the Himalayas. The Ayrshire and Boursalt groups are perhaps the most difficult to bloom, but they are not of such beauty or attraction as to render their absence from the Indian garden a matter for regret. Every Hybrid Perpetual, Tea and Hybrid Tea Rose can be made to grow and bloom perfectly, and with our choice Noisettes and Bourbons, added to some of the well-known Provence and China varieties, we have a wide range to select from. The hybridist goes on adding to the number of varieties every year, and it is a question with rosarians all over the world whether the great number of new Roses put on the market every year is commensurate with their merits. A large number of old favourites compare favourably with the new comers, and we are not sure whether a large proportion of the latter are really worth adding to our existing collections. —*Indian Planting and Gardening.*

Chrysanthemum names.—Your correspondent "A Hemsley" does well on page 407 to protest against the renaming of Carnations received from America, as this leads to no end of trouble as well as, in some cases at least, to pecuniary loss. Just the same confusion cropped up when the Japanese section of Chrysanthemums was beginning its present era of popularity, for a set of new varieties sent out by that noted raiser M. Simon Delaux in the spring of 1882 were by some cultivators treated in this way on reaching our shores, and as they were by others grown under their correct names a deal of confusion arose. Among them were the following, which, with their synonyms, are taken from the centenary edition of the National Chrysanthemum Society's catalogue: *La Bienvenue* syn. J. Hillier, *Source Japonaise* syn. R. Ballantine, *Tricolor* syn. Mr. J. Starling, and *Jeanne Delaux* syns. F. A. Davis, J. Delaux, *Japon Fleurie*. This last (*Jeanne Delaux*), though now almost if not quite discarded, was, to my mind at least, the most beautiful rich crimson-flowered Chrysanthemum that has ever been exhibited, possessing a grace and elegance that we do not find in the huge blossoms of to-day. —T.

Chrysanthemum Market Gold.—Among a large number of decorative varieties grown here for midwinter there is certainly none more beautiful than this new variety, and it stands out conspicuously. We have a good many plants of this just coming into perfection. It is a rich golden yellow, the flowers stand erect, are freely produced, the habit of the plant is all one could wish for, and the foliage is good. The National Chrysanthemum Society did well in giving this an award of merit at its late show. Either for market use or home supplies this will, I feel certain, prove to be one of the most valuable additions to this useful class during recent years. It is being sent out by Mr. H. J. Jones of Lewisham, and all who cultivate late-flowering Chrysanthemums should not fail to add this to their collection. —E. BECKETT, *Elstree.*

The Garden City Movement.—Last week Mr. G. M. Brown, M.P., gave a lecture on the Garden City Movement in Edinburgh. The lecture, which was illustrated by limelight views, was an excellent one, and was listened to with close attention by a good audience. Mr. Brown referred, among other phases of the movement, to what was proposed to be done at Hitchin by the Garden City Association, and spoke in eulogistic terms of such places as Bournville, Port Sunlight, and others where the provision of gardens to all dwellings had been secured. He also referred to the efforts being made to secure that similar provision should be made at the proposed naval base at Rosyth. Mr. Brown was warmly thanked for his interesting lecture.

Union of Dunfermline Horticultural Societies.—As was reported in THE GARDEN at the time, a meeting of the Dunfermline and East of Fife Horticultural Society and the Dunfermline Chrysanthemum Society was held

recently to endeavour to arrange a union between the two, and a committee was appointed to further the matter. An adjourned meeting was held in the Lecture Hall, Dunfermline, on the 17th inst., presided over by Mr. James Meldrum. On the proposal of Mr. T. Harrower, seconded by Mr. D. Murray, it was resolved that the old societies be dissolved, and a new one formed under the title of "The Dunfermline Horticultural Society." The other necessary steps in connexion with the union were taken, and the following office-bearers appointed: Hon. president, the Earl of Elgin, K.G.; president, Mr. James Dunegan, Pittencrieff; vice-president, Mr. James E. McKillop; treasurer, Mr. Thomas Kilgour, Thistle Street; secretary, Mr. John Hynd, Mid Beveridgewell; auditors, Mr. Samuel Bigham and Mr. John Burt. A committee of thirty-six members was also appointed. There is every prospect of a successful career before this society, supported, as it is, largely by the Carnegie Dunfermline Trust, who give grants for the promotion of horticulture.

Dundee Horticultural Association. The members of this association will hold their annual social meeting on January 20 instead of on January 13, as originally announced in the syllabus. These social events have hitherto been very successful, and it is expected that this will be no exception.

Lecture on Mosses.—On the evening of the 20th inst. a lecture on Mosses was delivered to the members of the Dundee Working Men's Field Club by the president, Mr. James Fulton. For some time Mr. Fulton has been cultivating and studying the Mosses, and the lecture was largely a summary of his experiments in their cultivation and propagation. Mr. Fulton also spoke of the conflicting views held regarding several questions arising in the life history and cultivation of these plants, and stated that he hoped shortly to be in a position to state more definitely some conclusions he had formed. He was heartily thanked for his lecture, which it is hoped may interest others in the district.

Broughty Ferry Horticultural Association.—The annual general meeting of the Broughty Ferry Horticultural Association was held on the evening of the 20th inst. There was a good attendance, presided over by Mr. James Slater. The annual reports of the secretary and treasurer were very satisfactory, both showing favourable results of the year's work. The treasurer's accounts showed a balance to the credit of the association, while that of the secretary recorded an increase of membership, and a larger attendance at the ordinary meetings. The prospects of this association are very promising for the new session.

Removing large trees at Hopetoun House.—In the course of some improvements at present being carried out in the policies at Hopetoun House, the seat of the Marquis of Linlithgow, it was found necessary to remove about twenty large trees from a wood two miles distant to a new position near the house. The trees were all of large size and of considerable age, but they have been successfully removed by Mr. Hay, Lord Linlithgow's gardener, and there is little doubt that they will thrive from the care with which the operation was conducted. The machine employed was that from Messrs. W. Barron and Sons, Borrowash, Derbyshire.

A winter-flowering shrub (*Hamamelis mollis*).—The *Hamamelis* or Witch Hazels are among the most beautiful of shrubs or trees that flower before the foliage appears, and as the curiously shaped blossoms expand in midwinter their value is much enhanced, the number of shrubs flowering at this season being very few. *H. mollis*, which was introduced from Japan a few years ago, is the best of the family, and has, fortunately, proved hardy with us in a very exposed position, and a specimen about 4 feet in height promises to bloom well during the early part of January. The individual flowers are composed of narrow, wavy petals nearly 1 inch in length, and the colour is a bright yellow, much deeper, in fact, than any of the other Witch Hazels, and last a long time in perfection, not

being injured by frost or excessive wet. The leaves are very ornamental and distinct from all other members of the family, being much larger, of different form, and the underside is covered with a dense mass of whitish hairs. For the beauty of the foliage alone this shrub is worthy of inclusion in the best collections, and on a cold clay soil it succeeds well here, and annually produces its pleasing flowers with remarkable freedom. —A. E. THATCHER, *Elstree.*

WINTER WAR AGAINST FRUIT PESTS.

A SEASON never goes by without some tale of woe being told about this or that fruit crop suffering through the ravages of a common insect pest, the like of which has worried growers for generations past, and seems likely to do so in the future, in spite of the spread of entomological knowledge, and the increase of approved appliances and insecticides. British fruit growers suffer in many ways through the lack of co-operation, and the question of insect pests is a case in point. If one united warfare could be waged throughout the land against insect foes, even if it only lasted for a year, we should hear less of their depredations. Many gardeners and commercial fruit growers try their best to keep their trees free from insect pests, but they are like a drop in the ocean and work under great difficulties, when one considers how many others there are who, unconsciously perhaps, harbour and encourage their own natural enemies.

No particular foe does equal damage every season, and in times when not much mischief is done growers believe that fate has favoured them; while, on the other hand, if they suffer severely they pity themselves for their misfortune, and treat the attack in much the same way as they would a severe spring frost, or some other calamity over which they have no direct control. This long-suffering spirit is tantamounting to the man who knows that the whole thing is really a question of fight; but he suffers in consequence.

The other day I had reason to complain to a nurseryman about some trees which he had sent out with a little American blight on them, and when apologising the man pointed out that he was the victim of circumstances. He does all that he can to keep his nursery free from woolly aphis, but close by there are several old orchards belonging to a man who would scoff at the idea of using an insecticide. The trees are perfect nurseries of American blight, the white woolly matter of which, containing the aphis, is wafted on the breeze to the young stock, and causes no end of trouble and expense to the nurseryman in question. This is not a solitary instance, but one of many in which growers who would keep their trees clean are discouraged from doing so through the thoughtlessness or carelessness of their neighbours. A better knowledge of the habits and life-history of common fruit pests is wanted. There is no excuse for ignorance. There are plenty of cheap books which contain it, and the Board of Agriculture distributes free leaflets, which describe every common pest of the orchard and garden and give remedies for extermination; but knowledge only comes to those who seek it. The fact is apt to be overlooked that the dull season is only a time of armistice, and that the enemy has only gone to winter quarters in the crevices of the bark, under the scales of moss and lichen which infest so many trees, and among the leaves and under the clods of earth beneath the trees, from where it will return and continue the campaign when natural conditions are again favourable. More than once I have seen growers disconsolate, when hungry caterpillars have stripped the leaves off large breadths of Gooseberry bushes; and yet it never seemed to dawn upon the sufferers, that the pests in a chrysalid state would be secreted in hundreds amid the fallen leaves and rubbish underneath the bushes, and by clearing all this out after the fall of the foliage, damage to a certain extent would be prevented the following season.

The time to fight insect foes is when it is practicable; but the great central attack should be made in the winter, with a view to lessening the need of a campaign during summer. A clean, healthy, looking fruit tree is a delight to a good gardener, but a specimen covered with green slime and lichen growth can hardly be healthy, because the pores of the bark are choked up with filth, and the cracks and crevices are the secret hiding-places of a host of insect pests. Again, if one looks closely at the bark of many an unhealthy Apple or Pear tree, it may be seen that the vitality of the specimens is being literally sucked out of it by thousands of tiny mussel scales adhering to the stem and branches.

The best time to destroy American blight is in winter, when growth is dormant and the trees can be got at without being hampered with foliage. In the old days it was customary to limewash the stems and lower branches of fruit trees in the interest of cleanliness, and this practice is still carried on to some extent. It is a good old remedy, but better suited to orchard trees than pyramids and bushes in gardens, and an objectionable drawback in the latter places is that limewash makes the trees look unsightly. Fortunately we have got a remedy which has no unsightly effect on the appearance of the trees, and is so efficacious that it leaves the bark looking bright and clean, and its effect on the life of insect pests is deadly.

The winter wash to which I refer is the now well-known caustic solution formed by a combination of caustic soda, pearlash and water. Those who do not care to go to the trouble of preparing the mixture themselves can obtain it prepared for dilution from a horticultural sundriesman but caustic solution is easily made. To make five gallons half a pound of caustic soda should be dissolved in water in a pail and half a pound of pearlash treated in the same way in another pail. In the meantime half a pound of soft soap should be dissolved in a little boiling water, and the whole, after being poured together, be diluted to five gallons. The solution may be applied to the stems of old trees by means of a stiff brush, but young specimens can be dressed with a sprayer, the idea being to just wet all parts of the tree with a thin spray. Gloves should be worn, and care taken to keep the solution away from the clothes and flesh, on account of its caustic character. The effect is that the bark on the trees is rendered clean and bright, moss growth is destroyed, as well as scale, American blight, and other insects. A dry day should be chosen for the operation, which may be performed any time before growth commences, but not after the buds begin to swell. Finally, it may be urged that the question of winter washing of fruit trees is a most important one, and if trees generally were operated on during the dull season we should hear less of the ravages of insect foes in the spring and summer.

G. H. H.

NOTES ON HARDY PLANTS.

THE PRAIRIE CONEFLOWER (LEPACHYS COLUMNARIS).

FREQUENTLY known as *Rudbeckia columnaris*, this is one of the most striking of the Coneflowers by reason of the prominence of the central cone, a feature which has gained for it in the United States, of which it is a native, the popular name of the "Long-headed Coneflower," another name for it being the "Prairie Coneflower." It is a pretty little plant, and a true perennial in most places, although there are some gardens in which it has not proved very hardy. Probably the plants which have died have been imported from some of its more southern habitats, as it is found in Tennessee as well as in the North-West Territories, and from Minnesota, to Nebraska, Texas, and Arizona. It is to be hoped that importers of such plants will endeavour to secure them from northern habitats, as these will probably be hardier in this country. As a border plant *Lepachys columnaris* is a desirable one, with its prettily divided leaves, stems bearing single flowers of a good yellow, with a greyish

central cone. The plant is from 1 foot to 2½ feet high, and should have a rather dry and sunny position.

Carsforth, by Dumfries, N.B.

S. ARNOTT.

CHRYSANTHEMUM MAXIMUM ROBINSONI.

THE old *Chrysanthemum maximum* has ever been a popular border plant, and quite a number of excellent varieties have been obtained from it in recent years, differing mainly in size of flower and in arrangement of petal, the pure white colouring remaining unaltered. Foremost among these newer forms stands *Robinsoni*, a handsomely border plant whose flowers compare favourably with most as regards size, whilst the really distinct feature is the finely cut ray florets of considerable length, giving the elegant appearance of a single white Japanese *Chrysanthemum*, combined with great sturdiness of stem and substance of petal. It is a refined border plant, very superior to others when in good flower, and it should be welcomed for its yield of cut blossom free from the rigid outline of so many giant forms of *C. maximum*. The Shasta Daisies, of which so much was expected, appear to have been considerably overrated; they are still in the transitory stage, and until good forms (a low percentage) are separated from the bad or inferior ones there is no real gain in them. It is possible, however, that good work is being undone by incautious selection of seed-bearing plants, thus perpetuating bad forms with the good.

G. B. M.

DAFFODILS PLANTED LATE.

I THINK Daffodils are the most accommodating of all our bulbs. Last Christmas a kind friend sent me a delightful present of 1,000 mixed *Narcissi* from Barr's, and for many an hour in the cold and wet of the last week of the old year I planted *Horsfieldi*, *Mrs. Langtry*, *Emperor* and *Empress*, *Orange Phoenix*, *incomparabilis*, and others of that charming crowd, feeling, however, as I interred the last bulb—though Barr's name is as good as his bond—a little doubtful of their flowering after such a late planting. When I returned to my garden at the end of March the little green swords, indicating where lay my buried treasure of gold, were cleaving the brown earth and pushing strongly through the herbage at the feet of the budding Apple trees. Later sheets of gold, gold and silver, and yellow and orange greeted me, and there was hardly one of the little army that did not answer its roll-call on the green slopes or among the older residents in the wild garden. They came somewhat later, it is true, but were all the more welcome, and mingled their gold with the blue of the *Forget-me-nots*, the paler yellow of the wild *Cowslips*, and the many-hued *Anemones* that jewel the orchard grass. Do you know the smallest of all the Daffodils, a veritable fairy queen that nods its tiny head on the turf of the Biarritz golf ground? There it is pale yellow; with me it is almost white, and I suppose, owing to the superior richness of the soil, grows a little larger. I have no name for it, but I believe it has been found in English meadows.

A. DE L. L.

MIGNONETTE.

I HAVE found *Mignonette* to be by no means a trustworthy annual. It is one of those flowers with ideas of its own, and it knows what it likes, and intends to have it; it also prefers to sow itself, and if it likes the soil—and there is always an "if" in this important particular—it becomes a weed, but such a charming weed, and always welcome. A few years ago there was only one variety of *Mignonette*—and truly its sweetness was its only grace—but now we have several to choose from, therefore, why have the old weedy kind at all? The new sorts are more ornamental as well as sweeter than ever, and the giant varieties only should be cultivated—*Matchet* being one of the best. *Mignonette* likes new soil; it refuses, as a rule, to grow in old gardens, but pass by the brand-new villa and you are met by its fragrance. It evidently does not care for very rich soil, but likes

lime and rubble, of which, of course, the new villa garden is full. So, if you find your *Mignonette* is capricious—which the little darling often is—give it lime. The wild *Mignonette* grows rampant in the chalk, so I suppose its distant cousin of the garden requires the same food. The original habitat of the *Reseda odorata* was North Africa, from whence it found its way through Italy to Paris. Lord Bateman brought the seed for us from that city in 1742, and, of course, it was the French who called it "Little Darling," though, strange to say, they now speak of it as *Reseda*, leaving its pet name with us. The *Matchet Mignonette* should be sown in August for winter flowering in pots, and may be grown to any size; but it requires watching, and must not be allowed to flower before it has attained a robust growth. Plants of *Mignonette*, pot-grown, may be kept for six or seven years, flowering profusely all the winter, and scenting our rooms with its delicious perfume.

A. DE L. L.

SCABIOSA CAUCASICA AND ITS VARIETIES.

THE valuable notes on these by "G. B. M." in THE GARDEN of December 10 suggest the desirability of raising the plants from seeds. It is possible, by doing so, that really superior forms may be secured, and, at the same time, the plants are generally more vigorous than those propagated by division, as is so often practised. The flowers on plants raised from seeds differ greatly, but from a good batch of seedlings forms may be selected quite as good as *S. c. perfecta*, and in some cases even superior in size of flower and breadth of petal. The form called *amena* is also a good one, with darker flowers than that shade which passes as the typical one; but varieties equal to it can be found among a good number of seedlings. It is not generally known that the white varieties also reproduce themselves to a great extent true to colour from seeds and from the resulting seedlings again one may select forms quite as good as *perfecta alba*. I recollect being struck with the number of good flowers of *S. c. alba* to be found among a large number of seedlings from seeds saved in a hardy plant nursery in the North, and raised in the same nursery. They were remarkably fine. I dare say some of your readers will have observed that in some gardens *Scabiosa caucasica* scarcely ever gives a perfect flower, generally some of the petals being absent, and the symmetry and beauty of the flowers are thus destroyed. This seems mainly to occur in poor soil, and in no gardens have I seen it more pronounced than in those where there is a large proportion of granite grit in the soil. "G. B. M.'s" hints as to liberal treatment for old plants are well timed, as this plant is neglected in many places, and eventually succumbs when starved.

S. ARNOTT.

STOKESIA CYANEA.

THERE are, as stated by "G. B. M." (page 313), two forms of this plant, one flowering at the end of July and through the month of August, and the other from mid-October onward. "G. B. M." stigmatises this latter form as a "useless variety," and it very probably is so in the colder districts, where the first frosts may generally precede the attainment of its full beauty, but here, in a warm spot in the south-west, it is certainly valuable, and, personally, I prefer it to the early-flowering form, since it perfects its blossoms at a time when there are fewer flowers in the open garden. This year, with the fine and calm weather experienced during the latter part of October and November, it has been particularly attractive, its large purple-blue Aster-like blossoms, produced in profusion, being quite unharmed by the weather. It is growing in front of bushes of *Aster grandiflorus*, another plant that, on account of its late blooming, is useless in the open in cold districts. In the first week of November these plants made a pretty picture, being then at their best, the deep violet flowers of the *Michaelmas Daisy* contrasting pleasingly with the lighter tints of the blossoms of the *Stokesia*.

S. W. FITZHERBERT.

COLONIAL AND FOREIGN FRUITS.

(Continued from page 428.)

PERHAPS the best known is the Granadilla (*Passiflora quadrangularis*). This fruit is oblong, sometimes 10 inches or 12 inches in length, and 6 inches in diameter. The skin is of a greenish yellow colour, and when ripe soft and leathery, containing a succulent pulp of a purple colour. *P. edulis* also has edible fruits, as its specific name implies. It is a native of Brazil but cultivated in the West Indies. The fruits are somewhat egg-shaped, measuring about 1½ inches in diameter, and as they ripen they change from green to purple. The pulp is orange-coloured. *P. maliformis*, known in the West Indies as the Sweet Calabash or Apple-fruited Granadilla, produces a larger fruit than the last named. It is of a dingy yellow colour when ripe, with a hard, thick rind, containing a very agreeable pale yellow pulp, which is often eaten in the colony with the addition of a little wine and sugar. *P. laurifolia*, which is known as the Water Lemon, is abundant in the West Indies and South America, and is cultivated for the sake of its fruit, which is about the size of a hen's egg, but rather more elongated, of a yellow colour when ripe, spotted with white. It has a delicate sub-acid, slightly aromatic flavour, possessing a distinct power of allaying thirst. It is said to last well after gathering.

A fruit that attracted considerable attention some ten years back was a Melon known as the Sarda Melon, specimens of which were received at Kew from Kabul, arriving at the beginning of January in excellent condition packed in cotton-wool. The flesh was described as being firmer than that of Melons usually cultivated in this country, and the flavour was found, after its long journey, to be excellent. With reference to this Melon the late Dr. Aitchison, in his "Notes on Products of Western Afghanistan and North-Eastern Persia," says: "Melons are largely cultivated as a field crop, but not to the same extent as the Water Melon; the variety Sarda keeps well, and is exported to India in great quantities during the winter, where it is much appreciated both by Europeans and natives. Europeans in India and elsewhere have tried to raise from seed the Sarda Melon. This has always proved a failure, the fruit produced being of a very ordinary form, and never having the flavour of the Afghan fruit. The word Sarda means cold, and subsequently came to mean the last fruits of the season left hanging on the trees when the main crop had been collected. The Melon collected from the plants that yield the Sarda whilst the season is hot and there is still no frost, is, comparatively speaking, an ordinary good Melon; but once the season is ending and night frosts have set in and the plants are beginning to be nipped, the gardeners carefully cover the fruit to prevent it from being injured by the frosts, and then collect it when not quite ripe. These fruits ripen very slowly, will keep through the whole winter, and in flavour seem to improve the longer they are kept. It is this treatment, I believe, that constitutes the difference between the ordinary Melon and the Sarda, and why gardeners out of Afghanistan and Persia have not been able to produce the fine flavoured Peshawur trade article, and

which, even in the old caravan (now railway) days, were carried in perfection to Southern India." Referring to this variety the *Kew Bulletin* says: "There seems to be no reason why it should not be imported to this country in quantity for consumption during the winter."

AVOCADO PEAR.—Under this name the fruit of *Persea gratissima* is known in tropical America and the West Indies, where the tree, which grows to a height of 25 feet to 30 feet, is common. It belongs to the order Laurineæ, and produces a fruit in size and shape like a large Pear, covered with a smooth brownish green or purplish skin, enclosing a large quantity of firm pulp of a rich buttery or marrow-like taste. It is sometimes known as Vegetable Marrow, or Midshipman's Butter. The flavour is said not to be quite agreeable to Europeans at first, but to gain upon them after a short time; in consequence those who are unaccustomed to its use often mix with the pulp wine, sugar, lime-juice, or some such flavouring agent. The fruit is in season in the West Indies from August to October. In many of the islands it enters largely into the food supply of the people.

BUFFALO BERRY (*Shepherdia argentea*).—A North American shrub belonging to the order Elæagnaceæ. It produces an abundance of small berries, somewhat resembling Red Currants, borne in clusters. They have an acid taste, and are much used in America. Quantities of these attractive-looking little fruits, preserved in bottles, were shown in the Canadian Court of the Colonial and Indian Exhibition in 1886; but so far as we are aware they have not become used in this country.

OTAHEITE GOOSEBERRY.—This is the fruit of *Phyllanthus distichus*, a tree of about 20 feet or 30 feet high, belonging to the natural order Euphorbiaceæ. It is a native of India, where it is common in gardens, as well as in Burma and the Andaman Islands, the West Indies, and other tropical countries. In India it pro-

duces, at the beginning of the hot season, numerous small reddish flowers, which are succeeded by small fleshy fruits of a green colour, and not unlike an ordinary Gooseberry. They are acid and cooling, and are much used as an article of food, either raw or cooked, in various ways, or made into preserves, and sometimes pickled. In Java they are regularly sold in the markets for preserving. In Dominica the fruits are produced in great abundance and are used chiefly in making preserves.

RAMLEH (*Baccaurea sapida*).—A small or moderate sized evergreen tree of Eastern Bengal, Burma, and the Andaman Islands. The fruit is about the size of a large Gooseberry, with a smooth skin and of a yellow colour. They have a pleasant acid taste, and are much appreciated both by Europeans and natives in the countries where they grow, being generally found in the Rangoon markets. The plant is, perhaps, better known as *Pierardia sapida*. An allied species, of Malayan origin (*Baccaurea* or *Pierardia dulcis*), has similar fruits, which are said to have a sweet, luscious pulp, and to be much in demand in Sumatra.

The foregoing list of edible fruits, though by no means exhaustive, covers a wide range.

THE ROCK GARDEN.

ROCK GARDEN-MAKING. — XX.

WATER IN THE ROCK GARDEN (Continued).

SMALL ponds and Lily pools in connexion with rock gardens have been already mentioned on pages 329 and 330 of THE GARDEN of November 12, when hints from practical experience were given and illustrated by a rock pond at various stages during its construction. I will now consider ponds on a

POND AT GNATON HALL AS IT APPEARED IN MAY, 1904. THE PROPERTY OF MR. C. BOWES.

larger scale, the alteration of existing ones, the treatment of the shore lines, preparations for Water Lilies, the formation of islands, &c., and I will illustrate my remarks by photographs taken during the progress of recently constructed work.

LARGE PONDS.

As in Nature there is nothing large or small except by comparison, the term "large ponds" may seem somewhat vague and indefinite. It might be as well, therefore, to state that by a large pond I mean a sheet of water of at least 50 feet to 100 feet in length, and, perhaps, half that width. Ponds which are several acres in extent are perhaps more accurately termed "lakes," and are not included in this discussion.

Generally speaking, the hints already given as to natural shape, &c., of small ponds apply to those of larger size with still greater force. Ponds of square, circular, or oval shape, perhaps even with a circular island in the middle, may do well enough for a duck pond in a farmyard, for a place for cattle to drink out of, or for a strictly formal garden, but in connexion with a rock garden such shapes would make a picturesque combination of rocks and water by natural effects impossible.

Even when the pond has to be formed by putting a dam across a natural valley, there is no need to spoil a natural outline by the ugly straight line of a dam. The wall which forms the dam might quite as well be built in a curve, and if the convex side of such curve is turned towards the sheet of water, the wall will be even stronger and resist more pressure than if it were built in a straight line. But even if for some reason or other the dam must be straight, this straight line can easily be so masked by irregular banks of earth and rocks on both sides as to appear perfectly natural.

Very often in the case of large or medium-sized ponds the water supply is such that a little waste does not matter, and if the natural subsoil consists of clay, the operations mentioned for making small ponds perfectly watertight may be needless in work on a large scale. If, however, the bottom consists of porous sand or gravel, the water will percolate through this very quickly, and the securing of sides and bottom by one of the methods previously described (see THE GARDEN of November 12) then becomes necessary. The best material for the purpose is undoubtedly cement concrete.

Sometimes it so happens that the ground forming the bottom of a pond is not solid, but consists of filled-up ground, which would settle down considerably if any heavy weight were put on it, or the ground may be of so soft a nature that the cement concrete would sink into it before it had time to harden, with the result that a series of troublesome cracks would appear, which are difficult to deal with. In either case I have found it a good plan to fix a network of strong fencing wire across the bottom before the concrete is put on. As the wire is completely embedded in the cement afterwards, it helps very considerably in holding the concrete together and making cracks almost impossible. I will now say a few words on

THE TREATMENT OF THE SHORE LINE.

As a general rule it may be taken as a fact that a pond—if some portions of it are partially hidden from view—will appear larger than it really is, because almost invariably the observer would unconsciously give imaginary extent to the hidden portions. To emphasise this effect the most prominent portions of the

shore line, such as promontories or other convex portions projecting into the water, should show bolder groups of plants or more massive rocks than the concave or receding parts, which might often be left quite bare with advantage.

Not unfrequently the sides of a pond are secured by dry walling, but, as in the case of small Lily pools, the practice of allowing the dry walling or any other kind of masonry to be visible above the water line is to be strongly condemned. A shoulder or bench below the water level, such as illustrated on page 327 of THE GARDEN, is most useful for supporting either stones, soil, or turf, and allowing these to dip right into the water, completely hiding all walling, &c., above the water line. A shore line treated on these principles will appear as being naturally continued below the water, and this is as it should be.

ISLANDS.

Many owners of ponds are anxious to have one or more islands in it. Not unfrequently a circular wall is built in the middle, the space so enclosed is filled with soil, and the island is finished! Now this method I consider altogether wrong. In Nature islands would only under most exceptional circumstances occupy the middle of a pond. In most cases they are the result of some disturbing influence on the shore, such as a landslip or the falling of massive rocks which have become detached from some projecting cliff, or by a promontory which was washed by water in such a way as to become eventually entirely separated from the shore. In the great majority of cases, therefore, we find natural islands near the shore rather than in the middle of a pond unless they were the direct result of volcanic upheavals.

The shape of islands, too, deserves our attention. Natural islands are never in the shape of a circle, but very often they are more or less wedge-shaped, with the head or blunt end turned towards the influx of the water and the sharp end directed towards the exit of the stream that feeds the pond. The reason for this is obvious. That side of the island which offers resistance to the incoming current would naturally become flattened or rounded off, while the other end, owing to the continuous grinding influence of the outgoing stream on either side, would become elongated into a sharp point.

PREPARING FOR WATER LILIES.

Water Lilies may, of course, be planted into flat baskets and then plunged into the pond in such a manner that the surface of the soil in the baskets is about 10 inches to 12 inches below water level. But I prefer another method, which for years I have used with great success. It consists in the construction of totally submerged rocky islands filled up with suitable soil to the required level of, say, 12 inches below the water level. Decaying leaves and good loam are an excellent mixture for the purpose; but in filling up this soil allowance must, of course, be made for its settling down as soon as the weight of the water is upon it.

ALTERING EXISTING PONDS.

Sometimes it may be desirable to construct a rock garden near an old pond of a shape very unsuitable for that purpose. In such a case an alteration of the shore line will be necessary, and, as an example, I will here illustrate a pond at Gnaton Hall which I remodelled only a few months ago. The first picture shows this pond with the water let out for the purpose of making alterations. It will be observed that the left side of this pond is formed by an absolutely straight wall; on the right a circular island, with a *Gunnera scabra* planted on

it, is partly visible. In the distance the straight line of the wall is lost in the dark shadows of common Laurels. The plank bridge connecting the island with the shore was rickety and dangerous. At the bottom of the pond will be seen a number of pegs marking out the proposed alteration of the straight line and the circle into more natural outlines.

Picture No. 2 shows the same pond two months later photographed, not quite but very nearly, from the same spot. From this it will be observed that the straight line on the left is completely altered; the Laurels and other rubbish were swept away, and their place is taken by a waterfall with a stepping-stone bridge in front of it. The large *Gunnera* remained intact, but the shape of the island was altered and planted with Iris and other moisture-loving plants; of the numerous Water Lilies planted only one is visible in the picture. The plants on the water margin include *Arundo Donax*, *Saxifraga peltata*, *Chelone Lyoni*, *Rodgersia podophylla*, *Senecio japonicus*, *S. tanguticus*, *Spiraea palmata*, *Iris laevigata*, German Iris, *Osmundas* in variety, many *Carex* and *Scirpus*, &c. The additional rocks, turf, &c., rest on a low wall, built to within 8 inches or so of the water level, so that no walling whatever is now visible, but rocks and green sward dip naturally below the water.

Elmside, Exeter.

F. W. MEYER.

TREES AND SHRUBS.

SOME TREES AND SHRUBS FOR THEIR LEAF COLOUR.

IN November most of our deciduous trees are bare, except some Cherry trees and the Oaks and Beeches. The Tulip trees have lost many of their leaves, and those that they retain are a soft yellow. *Sassafras* bushes and little trees are brilliant in shades of amber, salmon, fawn, and orange-red. Some pasture fields, bordered with colonies of these beautiful bushes, intermingled with Blackberry shoots and Sumachs, are very gay. The fields themselves are dull grey-green, burnt up in the long autumn drought, and only the marshes and water-courses are green and fresh, and still bright with autumn flowers. There are patches of blue *Lobelia syphilitica*, *Eupatorium celestinum*, and some late Asters mingled with the common Yarrow, which is one of the most persistent of our field flowers, sometimes lasting in bloom until Christmas.

The Birches still have a sparse covering for their upper branches; the brightest green foliage still decks the Plums; and some Robinias retain their summer robes, but much the worse for wear—shrunk, faded, tattered, and forlorn. The leaves on the Robinias have never learned how to grow old gracefully. They have no gala dress in which to prank themselves for the autumn display, and look like shabby gentility at a gathering of *nouveaux riches*.

The Purple Fringe, a charming shrub, is now beautiful in full dress of orange; it is also remarkable for the exquisite soft salmon-pink hues of its translucent young leaves in April, and I know of no shrub that will give more pleasing variety in a season's growth.

On descending to the lower shrubbery we find some Weigelas, Kerrias, and Euonymuses still retaining green foliage. Notable also is a group of *Spiraea Thunbergii*, *Spiraea Van Houttei*, and *Rosa rugosa*, the *Spiraeas* fresh green, and the *Roses* just beginning to show a hint of fawn and madeira colour.

Forsythias have a dull plum-coloured shading, and the Californian Privets, which have not shed a leaf, are purpling in striking contrast to a group of Thunberg's Barberries, cheery with sprays of orange and scattered scarlet berries, which are a godsend to the vagrant birds.

A good bushy specimen of *Enkianthus campanulatus* in this shrubbery turns first a dull maroon, and later a brilliant uniform cherry-red. Indeed, it is the Japanese and Asiatic plants that furnish most of our brilliant effects in late autumn. Besides the *Enkianthus*, the most striking plants at Rose Brake in November are the groups of Japanese Maples, the Japanese and Chinese Quinces, and *Parrotia persica*.

This last named little tree is not more than 12 feet in height, and is well clothed with handsome, somewhat Beech-like, foliage. The peculiarity of this tree is in the way in which its leaves change in the autumn. The margins of the leaves turn orange and red first, while the rest of the leaf is still green. Gradually the foliage becomes irregularly marked with shades and splashes of crimson and gold. I have long noted the fact that many of these Asiatic foreigners are the last to retain their leaves, owing, I suppose, to the difference in autumn temperature in their native haunts.

Usually our Ginkgos, or *Salisburias*, do not shed their foliage until the last of this month. It turns to a striking soft lemon-yellow before it falls; but this year all its pretty little fairy fans of leaves fell softly during a night of frost without waiting to change colour.

Coluteas are still a lively green, and so is the grass in this sheltered and comparatively moist situation: for the shrubbery borders a hollow between two gently rising little hills. *Cytisus nigricans* retains healthy leafage of a very dark plum colour, almost black. Can this deepening of the foliage be the origin of its specific title?

Nearly all *Spiræas* keep their summer dress until late, when many of them, notably *S. prunifolia* and *S. Thunbergii*, change to brilliant tints. *Spiræa lindleyana* is already losing its sunny sprays, while the little *Spiræa bumalda* and *S. callosa alba* are scarcely changed, except that their leaves have lost their pristine freshness.

Fontanesia phylliræoides is a rich dark green, and some *Hypericums* still make a pleasing spot of verdure for the eye to rest upon. The Golden Elder is golden still, and the Witch Hazel has adorned herself with tassels and fringes of gold, which she will lose by and by, while retaining her tiny inconspicuous yellow calyxes, stripped of their bright trimmings. These remain all winter to protect the ripening seed.

Chimonanthus fragrans is unchanged. It is hardy here. The white-flowered sweet-scented Southern Jessamine lives out even in zero weather, but it is always covered by a thick mulch of forest leaves. A group of *Itea virginica* is handsome in dull red, to which *Eleagnus hortensis*, with silvery foliage, forms a striking and beautiful contrast; but the pride of the grove at present is the great white Oaks, whose splendid masses of foliage are shot through and through with fire. Every day these bright flashes seem to spread and deepen.

"How small a tooth hath mined the season's heart!
How cold a touch hath set the world on fire!"

On the brow of the hill, as one leaves the lower shrubbery and saunters towards the house, stand two symmetrical spreading Dogwood trees (*Cornus florida*). One of these, the one that bears beautiful large white bloom in May, is losing most of its parti-coloured attire. The other one, which is the variety that bears large blossoms of an exquisite shade of wild rose-pink in May, always retains its foliage a week or ten days later than its neighbour. It is also much more brilliantly coloured, for while the first named Dogwood has foliage of a dullish crimson, the other sort has varied colouring of crimson, fawn, and sherry.

Our one specimen of that rather rare tree, the Chinese Quince, will probably be, as it usually is, the very last deciduous tree to hold its blood-red foliage. It grows out of a group of *Cotoneasters*, still showy in dark, rich crimson shadings.

November, in spite of its few late Roses, its flaunting display of bright *Chrysanthemums*, its gay lengths of scarlet *Salvias*, and its *passé*-looking

THE POND AT GXATON HALL AS IT APPEARED TWO MONTHS LATER.

Dahlias, touched by frost but still blooming bravely, is the month of the "melancholy days"; according to Bryant, the "saddest of the year." I think it must be more so in this part of America than in England, where no doubt the gardens are still fresh and verdant, and adorned with many flowers. But here the freshness has faded. The lady who wrote of wild Asters thus describes her November garden:

"Beneath the last October sun
My drooping garden lies:
A lovely woman, past her prime,
With haggard eyes.
She bloomed through many a sullen night,
Through many a sudden storm:
The breeze that fanned her tears away
Was soft and warm.
But now beneath the frost she lies
A lone, neglected spot;
Most like a heart by coldness chilled,
Where Love is not.
The butterflies that shared her youth
Share now her dim decay:
The birds that sought her in her joy
Have flown away.
But here and there amid the wreck,
The drift of leaves, appear
The hardy late *Chrysanthemums*,
To crown the year.
Strong, bright, courageous, as a smile
They cheer the withered place;
Like the last charm pale Sorrow leaves
A faded face."

DANSKE DANDRIDGE.

Shepherdstown, West Virginia, U.S.A.

SOME NOTES ON ROOTS.

DURING the last three or four weeks, while lifting various trees and shrubs, I have been much struck with the differences in activity between the roots of evergreen and deciduous subjects. Generally speaking, the roots of evergreens have been active, while those of deciduous plants have become dormant, or nearly so, depending chiefly, in the latter case, on the amount and character of the leafage. Where the leaves have nearly or entirely fallen off the roots have been at

rest, but where the foliage has been green or just on the turn the roots have been more active.

In moving Yews and Hollies, particularly in the early autumn after a few warm showers, the numbers of new roots are distinctly noticeable, especially near the surface, where the ground is warmest and dampest. I mention Hollies and Yews more especially, as the young roots of these plants are white and rather thick, and so can be more easily seen than those of some of the other evergreens. Though practically the same amount of root-action takes place with all evergreens, the young fibres are not so readily seen on some, *Coniferae* for instance, as on Yews and Hollies. This activity of the roots of evergreens in early autumn has an important bearing on the time to transplant them, as the more active the roots are the more likely is the plant to recover after being transplanted. An evergreen is never really at rest, therefore its roots are always more or less active, and in transplanting it the time when the roots are most active is the best period for moving it, always provided, of course, that the growth is fully ripe. This time is the early autumn, as soon as the growth has ripened, when the plant is full of vigour and most capable of coping with the check caused by moving it.

Deciduous subjects, on the contrary, can be moved at almost any season when the leaves are off, provided they are not going to be put on very damp ground where the roots are liable to rot before they make a fresh start. Where the ground is heavy and wet planting is best deferred until March or April. It usually happens that deciduous plants make very little growth the first season after being moved, the young shoots being short, while what leaves are produced are scanty in number and rather small in size. This is due to the fact that though the plants are rarely killed outright by removal, yet they suffer from the check given them, and for the first season are making new roots instead of much leafage. The leaves that are made are only produced in sufficient quantity to afford the help required by the roots until they have attained their proper balance in respect to the size of the tree.

In lifting various trees and shrubs, also I have noticed that the ground directly beneath evergreens

is nearly always moister in autumn than it is beneath deciduous subjects, when they are both growing in exactly the same soil and under the same conditions. I have never seen any reason given for this, but to my mind there are two, either of which, or both together, would account for it. In the first place, the leaves of deciduous trees and shrubs are, generally speaking, broad and flat, and arranged so that each leaf gets the full benefit of sunshine. Their arrangement is roughly somewhat that of the tiles on a roof, so that during rain the water runs from leaf to leaf to the outer spread of the branches, instead of passing through to the ground directly beneath the tree. In evergreens, taking the majority of cases, the leaves are so arranged that the rain comes through and falls on the ground beneath the tree. This can be seen with a Holly on a wet day, where the rain falling on the leaves is thrown more towards the main trunk than it is away from it. Old nursery hands who have worked out of doors for years always prefer a deciduous tree to an evergreen for shelter during heavy summer showers, as experience has taught them that the former do not let the water through so soon as the latter. In the second place, deciduous trees before going to rest take up all the nourishment they can find in the soil on purpose to plump up their buds and load their stems and branches with sap in readiness for the coming spring. This bears also on what I have said above about newly-moved deciduous subjects not making full-sized leaves the first season after removal. The sap that is stored up in the stems during autumn is partly used the following spring to assist in the formation of new roots instead of being almost entirely used in the making of new leaves as would have been the case if the tree had not been transplanted.

Bayshot, Surrey.

J. CLARK.

THE FLOWER GARDEN.

FOXGLOVES IN THE FLOWER BORDER.

IT is scarcely needful to extol the beauty of the garden Foxgloves, especially of the finest form of the white variety, and yet there is many a June garden in whose planting this grand plant has been overlooked. Its graceful spires will tower to a height even exceeding those of the strong-growing Delphiniums, as the picture shows, and its culture is of the easiest. Sown in spring in the reserve garden strong clumps are planted in the borders, when they are rearranged in October.

G. J.

FUCHSIAS IN THE FLOWER GARDEN

AMONG the dozens of plants used in the flower garden few can compare with the Fuchsias. The

great variety of ways in which they can be used, and the varying forms and heights to which they will grow at the will of the cultivator, render them invaluable. Whether the season be wet or dry, Fuchsias grow and flower from June till the frost cuts them down or they are removed for the planting of spring flowers. Flowering as plants will when only a few inches in height to upwards of 10 feet or more, the cultivator is given plenty of scope to show his skill in filling the positions at his command. It is not difficult to associate Fuchsias with other things, as, although the flowers are conspicuous, their colouring is quieter.

Bushy plants 1 foot or 18 inches in height should be used where the beds are formal or small. Larger beds may be filled with standards or pyramids, with a groundwork of another variety of Fuchsia or some other suitable bedding plant for contrast. In some gardens specimen Fuchsias are planted out year after year; this is an excellent method where big beds have to be filled. It is as well to grow on

will root in a week or ten days. Pot off singly as soon as ready, and if kept in heat they grow rapidly. By repotting when necessary good plants can be had when required for bedding out. A few of the strongest should be selected for growing out into specimens or standards as required. Cuttings in autumn can be obtained from the plants bedded out, giving the same treatment as recommended for rooting in spring. Being more woody than the spring cuttings, they will take rather longer to root.

GENERAL TREATMENT.

Unchecked growth from first to last is the secret of success; until the desired size is obtained never allow the plants to become root-bound. Different methods of pinching will be necessary according to the shape and size of the plants required. For standards the leading shoot must be encouraged. Pinch out all side growths till the desired height is reached, then remove the point and pinch at every second pair of leaves. For large specimen plants a good foundation is necessary.

The growths will need continual pinching, and it may be found necessary to pinch out the point of the leader several times to get well-balanced growth.

Old plants are very easily kept during the winter; a cellar, or out-house, where frost is excluded will be found the most suitable place for storing them, much better than under the stage in a cool greenhouse, as fire-heat will be necessary sometimes for other subjects in the house. This will have a tendency to start the Fuchsias into growth prematurely. It will be necessary to examine the plants at intervals during the winter, as if allowed to get excessively dry the wood will shrivel. In February, or early March, the plants should be introduced into

WHITE FOXGLOVES IN THE FLOWER BORDER.

a few plants each year, for when they are about five years old it is necessary to renew them, as after this age growth is not so luxuriant.

Large specimen plants in pots sunk level with the surface on the lawn or placed about on terraces form an imposing feature. Vases filled with Fuchsias are extremely pretty, some of the trailing varieties, notably Scarcity, being especially suitable. The yellow and variegated leaved varieties are suitable for colour bedding and placing amongst or as an edging to other subjects. From time to time during the summer, as the earlier flowering plants pass away, bare places will occur in the mixed borders. Fuchsias kept in pots and placed on the north side of a wall till required will be found very useful for filling up these positions.

Propagation by cuttings is the usual method of increase. Except in the production of new varieties few are raised from seed. Cuttings may be put in at any time when young growths 3 inches or 4 inches in length are obtainable, the usual times being spring and autumn. From a few plants started in a brisk heat in January plenty of cuttings can soon be obtained. Insert them in a light sandy soil, and place in a propagating frame with bottom-heat. Given proper treatment they

heat, and pruned back to within two or three joints of the previous year's pruning. When growth begins the plants in large pots, which have attained the full size required, should have a few inches of the top soil removed, and replaced with fresh compost. Shake away most of the old soil and repot, using a compost of two-thirds fibrous loam, one-third leaf-mould, sufficient sand to keep the compost open, and a sprinkling of well-decomposed cow manure. Place in an intermediate house till well covered with growth.

During the time the plants are making growth, if the weather is bright, syringing them two or three times a day will prove an assistance, and help to keep the foliage clean. Harden off and stand outside towards the end of May or the beginning of June.

Fuchsias when growing and flowering freely like plenty of water. Liquid manure, or a slight sprinkling of a good artificial manure on the beds, will be found helpful. The older and proved varieties are better for summer bedding than the majority of the more recent introductions, the flowers of which are larger and more suitable for the greenhouse. When exposed to strong winds

and heavy rains the large flowers are soon spoilt. The smaller freer-flowering varieties stand much better.

VARIETIES.

The following list includes a selection of the best for general cultivation: Ballet Girl, red calyx, white corolla; Charming, scarlet calyx, purple corolla; Earl of Beaconsfield, rosy carmine calyx, deep carmine corolla; General Roberts, rose-carmine, corolla a shade deeper; gracilis, a small-flowering red variety; Lady Heytesbury, white calyx, purple corolla; Mrs. G. Rundle, pale red calyx, salmon red corolla; Mr. H. Roberts, rose-coloured calyx, corolla a deeper shade; Rose of Castile (improved), white calyx, purple corolla; Scarcity, red, drooping habit; Wave of Life, scarlet calyx, violet-blue corolla, yellow foliage. Meteor, Sunray, and gracilis variegata are most useful variegated sorts, especially for colour bedding.

Hardy kinds must not be forgotten. For permanent beds or the fronts of shrubberies they make

weeds form practically all the attention necessary during summer. Corallina and Riccartoni are two of the best hardy Fuchsias.

A. O.

MUSA ENSETE.

FEW large leaved sub-tropical plants are more effective than the Madagascar Banana. The bright red marking of the under midrib is well shown up by the rich green of its giant leaves, which do not tear so easily as those of *M. Basjoo* (*M. japonica*).

conveniently go. After being started into growth in a warm house, they should be hardened off and again planted out.

In many places the Japanese species is quite hardy; the leaves are cut by frost, but the stems throw up fresh leaves in the spring, which quickly become of full length. When about 5 feet high *M. japonica* frequently flowers; these have a pleasing fragrance, somewhat suggestive of newly-mown hay. Except that it is smaller the inflorescence is similar to that of the edible-fruited

CATASETUM PILEATUM AUREUM. (Natural size.)

Bananas, the stout spike is at first erect, and as it elongates gradually bends over, finally hanging down alongside the stem for 18 inches or more. This species freely produces suckers even when wintered out of doors, and is very effective when grown in groups. *M. Ensete* must be propagated by seed.

Bodmin.

A. C. BARTLETT.

NEW AND RARE PLANTS.

CATASETUM PILEATUM AUREUM.

ON the 29th ult. this curious and also handsome plant was exhibited before the Orchid committee of the Royal Horticultural Society by Mr. T. B. Schlesinger, Bedales, Hayward's Heath. The flower is large and open, the lip being broad, concave, with a slight spur. The two petals are curiously formed and situated; their margins recurve into the concave upper sepal, partly hiding it, while the two lateral sepals emerge above the lip. The white column is erect, terminating

a good show and give little trouble. Except in the favoured parts of the south and south-west they have to be treated as herbaceous, being cut down annually by frost. They may be either pruned hard back and covered with ashes in winter, or the growth may be left on till March, when it should be cut back. Fork over the beds or borders, adding a little decomposed farmyard manure. Thinning out the shoots and keeping the ground free from

Both species grow more luxuriantly when planted in their summer quarters instead of being plunged in a pot or tub. They should be given a rich soil consisting of roughly broken loam, well-decayed cow manure, leaf-soil, and plenty of grit. When the leaves are blackened by frost the plants should be lifted and stored like Cannas. In the spring most of the remaining soil should be shaken off and the plants potted into as small pots as they will

in a bent point, and having two pointed appendages at the base. The colour of the whole flower is primrose-green, while in the centre of the lip, around the entrance to the shallow throat, there is a mass of deep sulphur-yellow. It was awarded a first-class certificate.

THE INDOOR GARDEN.

SOLANUM INTEGRIFOLIUM.

AS a greenhouse plant at this season of the year this plant, with its red fruit, makes a useful change from *S. capsicastrum*, so often met with. Although of little or no use as a market plant for greenhouse decoration, the fruits last on the plants for a long period. The seed should be sown in February or early in March in light rich soil, and the pans plunged in a hot-bed. When large enough the seedlings should be potted into 2½-inch pots. Keep growing freely, pot into 5-inch, and finally into 7-inch or 8-inch pots, using a compost of loam, manure from a spent hot-bed, and sand. The plants should be kept near the glass in a warm pit till the pots are filled with roots. Frequent syringing will be necessary, as they are very subject to red spider. If the plants do not break naturally the points should be pinched out at a height of from 15 inches to 18 inches. Allow two or three shoots to remain. As the flowers appear more air must be given, and weak manure water will be beneficial. The plants may be placed outside during July and August. It may be necessary to remove a few leaves to aid the ripening of the fruits and allow them to be seen better. The corrugated fruit is rich scarlet in colour, somewhat similar to and the size of a small Tomato. It is borne on the internodes singly, in pairs, and sometimes three fruits in a bunch. A group in the greenhouse at Kew is now very attractive. It is a native of Asia and Africa. *S. Worsleyi* is a closely-allied species with small egg-shaped fruits.

A. O.

RHODOCHITON VOLUBILE.

THIS free-flowering, cool greenhouse plant is a most useful climber, especially for the roofs of a small house. As a screen it is very effective. Although introduced from Mexico some ninety years ago, it is not met with frequently. The flower at a distance does not look unlike a *Fuchsia*. It is axillary, borne on long, thin pedicels. The name *Rhodochiton*, meaning a red cloak, refers no doubt to the large pale red calyx. The corolla is deep purple, almost black; leaves alternate, cordate, 3 inches long by 2½ inches wide; when young purplish green, attaining a brighter green with age. It grows to a height of from 15 feet to 20 feet. A plant on the roof of the greenhouse at Kew has been flowering since June. It is figured in the *Botanical Magazine*, tab. 3367. It may be propagated by seeds or cuttings. Young shoots inserted in August in a propagating frame or under a bell-glass root readily. Pot off when rooted, using a compost of loam, peat, leaf-mould, and sand. Grown on during the winter they will be ready for planting in the greenhouse in spring. It may also be planted in a warm position outside in May or June, where it will flower freely till cut down by frost.

A. O.

CALCEOLARIA INTEGRIFOLIA.

THIS, one of the true species of *Calceolaria*, has been in flower for months in a narrow border outside the Temperate house at Kew, and in the greenhouse it was also for a long time an object of considerable beauty. It is essentially of a shrubby character, forming as it does quite a bushy specimen from 3 feet to more in height, clothed with deep green ovate leaves about 3 inches in length. From the distinct roughened surface of the leaf it is sometimes known as *C. rugosa*. The flowers, which are arranged in

large branching panicles, are of a rich yellow tint, and from their quantity make a goodly show. Though quite an old plant in gardens it appears to be little known at present, and certainly merits extended cultivation. The "Kew Hand List" contains the names of several species, some of which, however, would be difficult to obtain outside a botanic garden. The list consists of the following:

C. alba, with curious narrow leaves and pure white flowers. Though by no means new it was almost unknown till given a first-class certificate by the Royal Horticultural Society in 1897. *C. amplexicaulis*, well known as a bedding plant, under which conditions its sulphur-tinted blossoms are borne in great profusion towards the end of the summer. *C. bicolor*, a rare species whose small yellow flowers are blotched with a blackish hue. *C. corymbosa*, yellow, dotted purple. *C. crenatiflora*, something like the last, but the flowers are fewer and larger, the parent of many garden forms, as is also *C. corymbosa*. *C. fuchsiofolia* syn. *C. reflexa*. About twenty-five years ago this *Calceolaria* attracted a good deal of attention, firstly, from its own intrinsic beauty: and, secondly, from the fact that it was supposed to be one of the parents (*C. Pavonii* being the other) of *C. Burbidgei*, which had been then just raised. This parentage is, however, doubted by some, and the "Hand List" gives *C. Burbidgei* (*amplexicaulis* × *Pavonii*). *C. integrifolia*, above alluded to. *C. lobata*, a yellow flowered species. *C. Pavonii*, a strong grower with curious winged leaves, but from a flowering point of view it is of no particular merit. *C. violacea*, a twiggly shrub, whose blossoms are remarkable from their pale violet hue.

Besides these a species not mentioned in either the hardy or tender list is *C. plantaginea*, a herbaceous kind, hardy at least around London, that reaches a height of 1 foot to 18 inches, and bears a great profusion of golden blossoms about midsummer. The little annual *C. chelidonioides* is not particularly showy, but interesting from the way it holds its own from self-sown seedlings every year.

T.

ERANTHEMUM PULCHELLUM.

THIS is now known as *Dedalanthus nervosus*, yet the former name is still adhered to in most gardens. The flowers are of a lovely blue, and open early in November. It is a valuable decorative plant for the warm house during the winter months, as with a little feeding it will continue to flower until quite late in spring. Young shoots root easily during March taken from plants that are cut back at the end of February for the purpose. When sufficiently rooted place the young plants in 4-inch pots, pinching out the point at the first pair of leaves, finally giving it a shift into 6-inch pots, using a mixture of loam, a little peat, and some sand. If the shoots are pinched out three times good plants will result without the aid of fire-heat from midsummer up to Michaelmas. We grow ours in an ordinary garden frame along with *Poinsettias*, *Centropogon*, *Coleus thyrsoideus*, &c. While it is in flower it looks a bit untidy unless the fading blooms are picked off, which should be done every few days.

AMARYLLIS AULICA.

THE brilliant crimson flowers of this are of much value from November onwards, whether as a pot plant or in a cut state, and those who do not happen to have the kind would do well to add it to their collection. It has long strap-shaped leaves of good substance; in fact, it should not be allowed to go to rest like the hybrids, when it will prove quite an evergreen species. After passing out of flower keep the plants in a vinery or early Peach house, where a little heat and moisture can be given it, so that it may finish its growth towards the end of April. Less water will suffice both overhead and at the root during the next three months. In August or early September the spike will be noticed pushing up, when an extra supply of water is needed, and a little weak manure water will add colour to the flowers. Repotting may either be carried out as soon as the flower spike

is noted, or it may be done immediately after it has flowered. The bulbs are very large and throw many offshoots, which soon make nice plants if treated liberally, using good fibrous loam, a little leaf-soil, soot, and silver sand. We have many just showing the two blooms which each spike carries.

Bicton.

J. MAYNE.

PENTAS CARNEA.

THIS is an old inhabitant of our gardens, and a useful plant, too, flowering as it does in midwinter. It has flesh-coloured flowers borne on the terminal growths similar to the *Bouvardia*, and can be had in flower throughout the year with a little forethought as regards pinching of the shoots. Being a native of South Africa a little heat is necessary to grow it well, and we find it does admirably if treated like *Begonia Gloire de Lorraine*. Young shoots readily root at any season. If put in during April and potted off as soon as ready, and shifted on as occasion demands, good bushy plants with a dozen or more heads of bloom can be had in pots 5½ inches or 6 inches in diameter. Pinch the shoots some half-dozen times between the months of May and mid-September. The plants should be kept regularly syringed. Loam and leaf-soil, with a sprinkling of peat and a little river sand, will grow this plant well, and if after passing out of flower it is cut back a little, and when new growth appears repotted, the plant will be in bloom again within a couple of months.

J. MAYNE.

IN former days when winter-blooming plants were not so plentiful as at the present time one frequently came across some well-grown specimens of *Pentas*. It is free growing and can easily be brought into flower for early winter. Plants that have bloomed should be cut over early in March, and when they have made new growths about an inch in length the old soil should be partly shaken away. Put them in pots a size larger, using a compost of fibrous loam, with a liberal share of leaf-soil or a little peat. Give good drainage, water sparingly at first. In the early stages of growth a night temperature of about 55° is necessary, rising in the daytime according to the weather. In July and August, when the wood is maturing, plenty of light and air should be given. During the winter months a temperature of from 50° to 55° will be enough.

Byfleet.

J. CORNHILL.

THE ROSE GARDEN.

YELLOW BANKSIAN ROSES.

WHEN grown on a sunny and sheltered wall in favourable positions this fair climber attains to much beauty in England, but even then it is not every year that it is permitted to adorn itself with its butter-gold rosettes of clustering flowers. Those who wish to realise the full luxuriance and beauty it is capable of must travel further afield and see it in Italy or on the Riviera, where it often smothers a tall tree with its growth and hangs down a tangle of golden glory from a height of 40 feet or more, that puts to shame the puny endeavours of less sunny climates. How much do we not owe to those who brought it from its Eastern home! The pretty single yellow form, presumably the wild type, was not introduced till comparatively lately. It has the merit of even greater vigour and luxuriance, and is quite a fortnight earlier than the double form. I have never seen the single in good flower in the North, but this earliness in warmer climates is an added beauty, as it hastens and prolongs the flowering season, which is all too short. Between the two kinds, however, one may

make up a full month of beauty, so that lovers of the yellow Banksian Rose should provide themselves with both the single and the double variety. There is, indeed, a second form of yellow Banksian Rose paler than the typical form, and its heads of bloom are less clustering and paler in colour, resembling exactly the double white in habit, and a little less decorative. It has, however, the faint sweet scent of Violets that is denied to the more effective type, so the *Jaune Serin* should be allowed a place where climate and space allow it to show to advantage, for the attractions of a yellow Rose, be it big or be it little, are not to be despised when coupled with so much grace as the Banksian Rose affords.

E. H. WOODALL.

THE LILAC.

(*SYRINGA VULGARIS*.)

ALTHOUGH not a true native of Britain, the common Lilac has been in cultivation here at least 300 years, and no flowering shrub, either native or foreign, except the Rose, has become more closely identified with English gardens and English country scenes. Of the latter none is more characteristic of our flowery May-time than the cottage garden with its fragrant, blossom-laden Lilacs. The common Lilac is a native of Eastern Europe, and although it appears to have been originally introduced from Persia about, or previous to, the year 1597, it was found to be a native of Southern Hungary, in the region of the Danube, especially on the chalky precipices of the Cverna Valley and on Mount Domoglet. It is not found truly indigenous further west than these localities, and it is not, as has been stated, a native of Italy, although no doubt it has become naturalised there and elsewhere. Besides the ordinary Lilac and its white variety there are many beautiful forms that have been raised in gardens with flowers double or single, and of colours ranging from purest white to a very rich red-purple. The following may be mentioned as some of the most desirable of these: *Souvenir de L. Spath* (the darkest coloured of all the Lilacs), *alba grandiflora* (a fine white), *Marie Legraye* (perhaps the finest of the whites), *Charles X.*, and *La Ville de Troyes*. Of the double-flowered ones may be mentioned *Lemoinei fl.-pl.*, *Mme. Lemoine*, and *La Tour d'Auvergne*. There are dozens more.

B.

THE KITCHEN GARDEN.

THE VALUE OF CELERY AND CELERIAC.

COOKED Celery may with advantage be eaten by those who cannot eat it in a raw state. Celery is doubtless of more value as a vegetable than many would think. Few vegetables are more delicious. I have been told that Celery is quite as valuable as Grapes or Apples when used in unlimited quantities, that it has certain medicinal qualities, and that there are few better foods for those who suffer from biliousness. My doctor friend even goes further, and says that as a tonic for the nervous system it is most valuable. I feel sure we could with advantage use all kinds of vegetables, especially green ones. Celery is not regarded as a profitable vegetable, as much of the outer leaf cannot be used, but this is not so when cooked as a vegetable, as the green parts, even the leaves when boiled, are good, but the last are more valuable for soups, as they are of stronger flavour. Celery cannot always be bought in a fresh state,

but if not frosted it will keep fresh a long time, so that if possible it should be got when firm. If wrapped in a damp paper or cloth and then placed in dry paper or in a place where the air cannot reach it, it keeps fresh much longer. I have kept roots six weeks in the spring in a cool store quite dark, the heads wrapped in paper, except the green portion, and the roots just touching the water. In spring, when the weather becomes warmer, Celery when lifted may be kept some time; it becomes tough and flavourless in the growing quarters.

Just a note as to the cooking, and here I may be taken to task, as cooking is not connected with the culture, except that we are often blamed for poor vegetables when the cooking is at fault. The common way of serving whole Celery is in a stewed form, and served with white sauce or brown gravy it is delicious. Few vegetables are more appetising than Celeriac, the Turnip-rooted Celery, which is even more solid than the ordinary Celery, and much liked. This can be cut in slices and fried or served cold. On the Continent Celeriac is a favourite winter vegetable, and with advantage could be more largely grown in this country. I have referred to stewed or boiled Celery, and Celery cooked in the same way as Seakale is excellent. Celeriac, though closely allied, is quite a different dish, but of great value. The root is the edible portion, not the stalk, and when the roots are lifted and stored they keep well until the spring.

Fried Celery is a dish not much known. The white part is used and cut in lengths of from 3 inches to 5 inches, sprinkled with salt, dipped in an egg well beaten, covered with breadcrumbs, and allowed to dry, as much of the egg and crumbs being used as possible. The lengths are then fried in boiling fat and served very hot. Another way is to cut in lengths and boil for half an hour in brown gravy and serve on toast, and for this purpose the solid or root portion is delicious. The Celeriac may with advantage be used in this way, cut in slices half an inch thick, and served as advised. Two large pieces of cut Celeriac will cover a small round of toast.

Baked Celery is liked by many, and this is prepared by placing the stalks cut up small in good stock, then adding salt and flour to thicken, first cooking it for half an hour before the last two are added. Many also use butter freely with the flour. Celery and cheese are by no means a poor dish, and here Celeriac may be used. The Celery is cut in lengths and partly cooked in water. Then place in a dish, cover over with breadcrumbs and finely grated cheese, and add a few lumps of butter, salt, and other seasoning. Bake for a quarter of an hour and serve hot. This is a very

nice dish after the sweets are served. Celery chopped fine may also be used as stuffing with breadcrumbs and butter. This is very good with chicken, and the green portion may be used for this purpose. Doubtless there are many other ways of using this vegetable. For instance, the roots of large Celery or Celeriac may be served like large Onions braised with rich gravy, and the tops come in useful for other purposes.

G. WYTHES.

POTATO EASTERN STAR.

AMONG the large number of new Potatoes seen during the past season the above variety will, I feel certain, take a foremost position when introduced to the public, not only as an exhibition variety, but, what is of far more importance, its table qualities are all one could desire. The parentage will almost ensure this, being *Windsor Castle* and *Snowdrop*. Grown under equal conditions, the raiser, Mr. J. H. Ridgewell, of Potato fame, assures me that from forty sets of this and *Northern Star* he obtained $\frac{1}{2}$ cwt. more from the latter, and no trace of disease. Mr. Ridgewell staged a very fine dish of it at the late National Potato Show held at the Crystal Palace, and its taking appearance called forth much favourable comment; it appears to have the qualifications of a first-class Potato. High table qualities should be the aim of all Potato raisers, for without this, however handsome a Potato, it is of little value. Far too many of the present day varieties are practically worthless when cooked. E. BECKETT.

LILAC MARIE LEGRAYE.

POTATO SUTTON'S DISCOVERY.

Of the many new Potatoes recently brought into commerce none has proved more prolific or of better flavour than the above. It is one of the many good things sent out by the firm of Messrs. Sutton and Sons, and one may rely on the fact that it would be thoroughly well tested before being placed on the market. I obtained 2lb. of this Potato for trial early in the year, and with no artificial propagation, merely cutting up the largest of the tubers before planting, the yield was 73lb. in all. There were very few small ones, and all the tubers turned out with a good skin and no trace of disease. The haulm grew tall and branching, with a dark green colour, and was rather late in ripening. One can confidently predict a good future for this Potato as a standard maincrop variety.

Drumpeiler, Couthbridge. P. S. FOLLWELL.

LIME FOR THE GARDEN.

LIME is the best manure that can be applied to some soils, for it is not only a necessary plant food in itself, but it sets free other plant foods already existing in the soil in an unavailable condition, though in many soils it exists in such abundance as chalk (*i.e.*, carbonate of lime) that any application of it is quite unnecessary. Where garden soil has been well manured for many years it is almost certain to become poor in lime, even though there may be plenty in the subsoil. Every time the rain reaches the subsoil it carries down with it some of the chalk from the surface in solution. The more highly the ground is manured with animal manure, the greater the amount of lime likely to be lost in this way. Some artificial manures, too, make great demands upon the lime of the soil, *e.g.*, superphosphate of lime and sulphate of ammonia.

It may be as well at the outset to mention the valuable purposes which lime serves in the soil. It provides a real plant food. The ash of the Gooseberry contains 12 per cent. to 14 per cent. of lime; that of the Apple 4 per cent. to 8 per cent., according to size; and that of the Plum 10 per cent. to 15 per cent. It strengthens the stems and woody portions of trees, producing short-jointed growth, and hastens the time of maturation of both wood and fruit. It serves to counteract the sourness in the soil which is caused by the breaking up of organic matter into carbonic acid, &c., and as the putrefactive germs cannot carry on their work in an acid medium this is of great importance. It is essential for nitrification—the conversion of ammonia into nitrate, this latter being the only form in which nitrogen is absorbed by the plant to any extent. When nitric acid is formed it unites with lime to form nitrate of lime instead of going off into the air. It renders available much plant food which is locked up in the soil, as mentioned above, especially nitrogen and potash, setting the latter free by decomposing or breaking up the minerals containing it. It serves to retain potash and ammonia in the soil by changing and modifying their form.

In clay soils it coagulates the clay and renders it friable, thereby making the soil of better texture. It checks many diseases and pests in the soil, such as clubbing and galling, Turnip flea, &c. Lastly, the presence of a sufficiency of lime in the soil is necessary if the application of superphosphate of lime is not to be injurious to the tender rootlets of plants.

Lime being so important, it behoves every gardener to know if his soil is in need of it. Mr. A. D. Hall, in his book on "The Soil," gives the percentages of lime as carbonate in the surface soil of certain typical agricultural soils, and these may be interesting to some. On the London clay formation heavy clay contained '35 per cent. of lime, and clay loam '06 only. Gault clay gave '04 per cent., calcareous loam 3·7 (subsoil 14·9 per cent.), red sandstone '96, the lower greensand '2, and the millstone grit '26 per cent. It is estimated that '1 per cent. means from a ton to a ton and a-half of lime in the top foot of soil on an acre of ground,

and any soil containing less than '3 per cent. (some say '4 or '5) needs to be limed if it is to be brought to a high state of productivity by manuring. It must be borne in mind, too, that an agricultural soil containing '35 per cent. of lime as carbonate (*i.e.*, chalk) will, after a few years' heavy animal manuring and cropping, contain a good deal less than this. On such soils much organic manure is wasted, as so much of it only goes to increase the store of humus in the soil and does not become available for the plants' needs, whereas lime would render any other manure except, perhaps, phosphate unnecessary for a couple of years or more.

Fortunately, anyone can test the needs of his soil in this respect for himself without getting a detailed chemical analysis. If some soil is taken from several different parts of the garden and well mixed together, a small portion of the mixture put into a test-tube or even into a tumbler, and some hydrochloric acid poured upon it, it should effervesce freely if there is a sufficiency of lime present. If it only slightly effervesces or not at all the first thing to do is to apply lime in some form or other to that soil. The form in which it will be applied will depend upon the ease and cheapness with which the different forms can be obtained, though all do not take effect with the same rapidity.

Where a garden soil is deficient in chalk through ages of manuring and cultivation, but there is plenty of chalk 2 feet or 3 feet down, the fertility of the soil can be much improved by bringing a little of the subsoil to the surface and spreading it over the soil every year. This can often be done without much extra labour when stations are being prepared for planting trees, &c.

When chalk is thoroughly burned it gives off 44 per cent. of its weight as carbon dioxide, the remaining 56 per cent. being quicklime. If the soil is very heavy quicklime may be applied with advantage, as it will coagulate the clay and render it friable. Slaked lime (*i.e.*, the fifty-six parts of quicklime united with eighteen parts of water) is more generally used, and it has the advantage of being a very fine powder when freshly slaked. Both should be applied in the winter, as they are injurious to the roots of growing plants. If quicklime is used, about 8lb. to 40 square yards is a sufficient dressing, but when slaked lime is used, which is not only less active, but has one-fourth of its weight water, 12lb. or 15lb. may be applied to 40 square yards.

On heavy soils needing lime these applications will result in the liberation of vast quantities of hitherto unavailable plant food. On a sour soil the products of decomposition—carbonic, nitric, and humic acids—preserve the organic matter from further waste, but when lime is applied it neutralises these acids, and decomposition goes on again at a great pace.

On light soils it is safer and better to apply lime in the form of chalk. It should be broken up into fairly small lumps and well mixed with the surface soil, 1lb. to 2lb. to the square yard (*i.e.*, 2 tons to 4 tons to the acre) being applied. The lumps lying upon or near the surface during the winter will become thoroughly disintegrated by the frost and rain. Gas lime is the most easily obtained form of lime in some places, and is a cheap and valuable manure, but very dangerous, as it contains compounds of sulphur, which, if applied to the soil imprudently, may render the soil unfit to grow anything for a year. If applied at the rate of 10lb. to 40 square yards in the autumn or early winter it will prove a beneficial application.

It is not so valuable, weight for weight, in some respects as lime or chalk, as by the time it has lost its dangerous properties it becomes chiefly gypsum, which, being itself a salt, does not neutralise the acids of the soil, at least until it breaks up. Gypsum itself (sulphate of lime) is very good for clay soils which have been heavily manured for some years, and should be applied at the same rate as the gas lime. It is also an excellent material to mix with the manure heap to prevent the ammonia from escaping into the air. The carbonate of ammonia of the manure unites with the sulphate of lime and we get sulphate of ammonia and carbonate of lime. Its effect in liberating the potash in the soil is greater than the effect of lime.

In whatever form the lime is applied it will have a beneficial effect in lessening the multitudes of pests which thrive in a soil containing large reserves of animal manures. In such a soil the roots of plants are often so mutilated by various things that they are unable to make full use of the store of food provided for them. Notably is this the case with the parasite which produces clubbing and galling among the members of the Cabbage family. Many flowers, too, such as Canterbury Bells, Primroses, Antirrhinums, Carnations, Foxgloves, &c., often get their roots eaten completely away in such soils. The effect of quicklime upon slugs is known to every gardener, a very slight sprinkling being sufficient to curl them up. It is said that two applications are necessary, as the slugs are able to counteract the first by exuding lime, but cannot cope with a second.

In the application of quicklime and gas lime care must be used not to overdo it. Though lime in small doses accelerates decomposition in the soil, large doses may stop it altogether, and the soil be rendered barren for a year or more. The preservative effect of lime in sufficient quantity is well known, but we do not want this action upon the soil.

ALGER PETTS.

A GENERAL CALENDAR.

THE end of December is a time of rest for most plants, but there is no rest for the true gardener. He can always find something necessary to do. There is the planting to complete, lawns to finish, paths to mend, drains to lay down, and many vacant plots to dig up.

If not done in autumn, advantage can be taken of the slack time to train and tie in climbing Roses. This work is often left until the spring, when work comes in with a rush, and the result is that this necessary work either gets half done, or is neglected altogether.

Store and greenhouse.—The work here is rather of a preparatory character for more active operations next month, but in the meantime Palms, Dracenas, Crotons, and other foliage plants may receive a good cleaning with warm water, soft soap, and a piece of sponge, for during the winter many of these plants become not only greasy and dirty, but infested with various insects. At the same time, a fumigation of the house would assist in keeping down the pests. The regulation of the temperature in the stove is of more importance during this and the next month than at any other period of the year. An even night temperature of about 60° should be maintained, for when considerable fluctuations occur, more harm is done than we sometimes imagine.

Camellias.—These are our greatest resource for flowers during the early months of the year, and if they are to develop their blooms freely, a little weak liquid manure should be given, which would assist them in that process. To preserve the young wood on small choice plants, screw off the blooms and wire them on to a sprig of foliage cut from another Camellia plant of inferior or stronger habit.

Caladium bulbs.—Those who set store upon these handsome, fine-foliaged plants will do well to keep an eye upon them just now. If they are still in the pots in which they made their growth, they should now be shaken out and carefully cleaned. If there be any symptoms of dry rot at the base it should be removed. This disease will occur under the best management at times. The best method of keeping Caladium bulbs is to cover them in silver sand after having cleaned them. Then they should be kept in a warm place, not far removed from the hot-water pipes being a safe position. Here they may require a little water occasionally to keep them from shrivelling.

Annuals for summer cutting.—A piece of ground should now be prepared for these. A well-dressed and deeply-dug border is the most suitable, deep tith, and what is commonly known as a good heart in the soil, being answerable not only for better quality in the individual flower, but for a much

longer display. A few really good things for the purpose are Carters' Plume Asters, White Spiral Candytuft, Marguerite Carnations, single Clarkias and Cornflowers, Gaillardias, Ten-week Stocks (the branching habit of these makes them very valuable), Scabious, miniature single Sunflowers, Sweet Peas, and plenty of Mignonette. When ordering annuals care should be taken to secure the best strains of different varieties, and to see they are likely to be adapted for the purposes of which they are required.

Preserving Poinsettias in a cut state.—Just now, when flowers are rather scarce, this hint may be useful. Poinsettias may be preserved if, immediately after they are cut, the ends, to the length of about an inch, are immersed in boiling water for two minutes; this does not prevent the absorption of water by the stems, consequently the bright green foliage, as well as the coloured bracts, are preserved in a perfectly fresh state.

Norwich.

T. B. FIELD.

PACKING GRAPES.

NO work associated with Grape culture, whether intended for market or for private consumption, is more important than a practical knowledge of the best method of packing. All the year's work may be undone in a few minutes by careless packing. It is to the perfection of size of berry, colour, and bloom that the greatest effort of every good cultivator is directed, and to have these qualities destroyed by carelessness at the last moment is unpardonable. With reference to the work of placing the Grapes on the table at home in good condition there is a certain amount of packing needed even here, as they have to be carried from the garden to the house, whether the distance be long or short. The first thing to provide is a cross-handled basket 6 inches deep, and large enough to hold six or seven good sized bunches, each weighing say from 1½ lb. to 2 lb. I prefer to have two baskets to carry 2½ lb. of Grapes than one. On the bottom of the basket place a layer of wood wool half an inch thick, and upon this and round the sides a sheet of soft packing paper. Take the basket ready prepared into the vinery from which the Grapes are to be cut. Disentangle the bunch about to be severed from any string which may have been used to support the bunch. Then cut the shoot to within 3 inches of the bunch on either side of it. I think that a bunch of Grapes without a portion of the shoot attached loses a good deal in appearance. For carrying a short distance lay the bunches in the basket so that they do not touch each other. The gardener should place them on the dessert dishes or fruit stand, taking care to lay them with the same side downwards as in the basket. If this part of the work has been carried out carefully the bunches will appear on the table with the same perfection of bloom as when hanging on the vine. I have been horrified at seeing some inexperienced person in the house take hold of the bunch instead of the stalk, and crush it into position on the dish, utterly regardless of the bloom.

As regards packing Grapes for transit by rail, whether for sale or for private use, it is of course not possible for the Grapes to arrive in the same perfect condition as when delivered by hand. Yet by knowing the best method of packing and by careful handling, it is wonderful in what splendid condition Grapes now reach

ALICANTE GRAPES IN HAMPER AS PACKED FOR MARKET.

the market. It was the custom some few years ago to pack Grapes in boxes with separate compartments for each bunch, the same as those used for packing Peaches, with the result that they were usually received in a deplorable plight. That system, I am glad to say, is no longer practised, but has given way to a much simpler and better method. For the boxes cross-handled baskets have been substituted.

One of the chief advantages claimed for this improved method is that the baskets cannot be turned upside down by porters and others responsible for handling them. These must be carried by the handle, hence the immunity from so much damage. The practice of packing Grapes for market most commonly in vogue among growers who can deliver the fruit by road is first to place the Grapes in shallow baskets or trays (which are known in the market as baby baskets). These are in turn placed in flat baskets, large and deep enough to hold them with lids to close over, and are then taken to market, as shown in the illustration.

Another way of packing Grapes, if they have to be sent a considerable distance by rail, is so to arrange them that the top side of the bunch does not come in contact with anything likely to rub off the bloom. It is to line the basket in this case the same as recommended in the former one, with wood shavings both bottom and sides, covering with tissue paper specially prepared for packing fruit, then to place the bunches round the sides of the basket, allowing the base of the bunch to rest on the bottom, at the same time securing the top of the bunch to the rim of the basket by tying the piece of shoot attached to each bunch with a piece of string. Take care that the tops of the bunches are placed lower than the rim, so that the paper cover placed over the basket may not come in contact with the berries to rub them. This is a safe way of packing Grapes when they have to travel a long distance, as with a covering of stout brown paper over the basket, leaving the handle bare

and free, no harm can come to the fruit with ordinary care.

Another method favoured by many gardeners is to have a similar basket about 10 inches deep, large enough to hold from 12 lb. to 15 lb. of Grapes, and prepared in the same way as regards lining with packing. Place the empty basket partly on end at an angle, say, of 60°, building the bunches from the bottom one upon the other until the basket is full, taking care that each bunch rests fairly tightly against the other as the work proceeds to prevent oscillation in travelling. More fruit can be packed in the same space in this way than in the other previously mentioned, and in general practice this is found an excellent and economical system. Some growers prefer to wrap each bunch—before placing in the basket—in tissue paper, but I have found no advantage in this. Grapes packed in either of these ways, when the top of the basket is secured with a covering of strong brown paper fastened down with string, will travel any reasonable distance without injury to bloom or berry. Printed address labels should be used, indicating in bold letters the contents of the baskets, so as to give no excuse for rough usage on the way. OWEN THOMAS.

GARDENING OF THE WEEK.

INDOOR GARDEN.

PROPAGATION.

PROPGATE by cuttings, as well as leaves, the various winter-flowering Begonias, for the earliest rooted have a good opportunity to grow and form strong plants by next autumn. There is no difficulty in rooting quickly and satisfactorily the tops of Crotons, which may be taken off and inserted in sandy soil in 2½-inch pots, afterwards to be plunged in a bottom-heat of 80° to 95°. To keep the surroundings moist and close plunge them in a frame placed upon the propagating bed. It is easy also to have plants large enough for dinner table

use in a short time by rooting the large tops while on the plants, which is done by notching the stems immediately below the crown leaves of plants that have lost their bottom foliage. The notches afterwards are tightly packed with sand, the air being excluded from the cut part by placing moss over it, which should be tightly bound and tied in position. Keep the moss and the plants in a hot-house; then roots will soon form. Sever the rooted tops from the parent plants and repot them into suitable sized pots. Increase the stock of *Dracænas* by this means also.

As the earliest inserted cuttings of Tree Carnations form roots, repot them as soon as possible afterwards. To have fine plants of *Coleus* by early summer insert the cuttings at once, and they will readily root if plunged in a bottom-heat. To ensure having a good stock of trailing plants for decorative work, insert periodically a few cuttings of *Panicum*, *Fittonia*, *Tradescantia*, &c. They are the most useful when propagated in the pots in which they are to be used, 3-inch pots being perhaps the best adaptable, four to five cuttings in each pot. *Cinerarias* need air in abundance at all times, and a light shade during sunny weather will keep their large leaves from flagging. Keep them free from green fly and thrips.

MASDEVALLA SUAVEOLENS.

This is a creeper that during this season be given abundance of air or it will often fail to flower. The growth should be well matured and must now be pruned, no weak shoots being left to crowd the stronger growth that under favourable circumstances would be bound to flower.

Tranby Croft Gardens, Hull.

FRUIT GARDEN.

LATE GRAPES.

The Grape room should be prepared, the bottles filled with soft water, and the Grapes bottled. The sooner this is done in the new year the better. In a dry, cool atmosphere, with good ventilation and a temperature of about 45°, the Grapes will keep in good condition for months when well ripened. Cut each bunch carefully with as much wood above and below as possible, and remove decayed berries before fixing in the bottle. Afterwards prune the Vines and clean them, wash the house and top-dress the borders, open wide the ventilators so that the Vines may have complete rest. The border not recently having had much water should now be thoroughly watered.

MELONS.

If early Melons are wanted, and they are often more appreciated early in May than later when other fruits are plentiful, have the house well washed and painted, if necessary, and the walls washed with hot limewash. Plenty of top and bottom-heat is essential. Make up a bed of short horse litter and leaves, chiefly the latter, over the hot-water pipes. If planting out is preferred, form a ridge of fairly strong loam, wood ashes, and lime rubble, and make thoroughly firm. When the soil is warm through, sow seeds about 18 inches apart, two or three seeds in each hole, and remove the weakest plants later. Select strong growing and free setting varieties for early work, maintain a moist atmosphere, with a night temperature of 65° to 70°, with a rise of 10° during day.

PROTECTING FIG TREES.

If the protection of Fig trees is considered necessary the branches should be untied and brought together and covered with mats or straw. The chief object is to keep the wood dry, and when well ripened it will withstand severe frosts without injury. The roots should also be protected with a liberal covering of dry Bracken or straw.

THE FRUIT ROOM.

The fruits should be examined frequently, and all decayed ones removed, as these often make others near by decay. Complaints are general of fruit keeping badly, and Pears especially are ripening earlier than usual. Give a little ventilation when the weather is favourable and cover up

doors and windows when severe frosts occur to maintain as even a temperature as possible.

Limpney Gardens, Droithwich. F. JORDAN.

KITCHEN GARDEN.

CUCUMBERS.

THE weather lately has not been of the best for this crop. The dull and sunless days soon tell on these plants; the growth becomes thin and weakly. Much may be done if careful attention is paid to the plants and borders. Sprinkle the beds frequently with light dressings of loamy soil to which has been added some leaf-soil and bone-meal. Where a vigorous root-action is kept up the plants will soon recover after the days begin to lengthen. No liquid or artificial manure need be given if the beds are regularly top-dressed. The roof-glass should be frequently washed down. Where winter Cucumbers are grown on hot-bed material careful attention must be paid to watering. Little syringing will be required at this period, but the floors and walls may be damped daily. The temperature should be about 70°, falling a few degrees in very severe weather. See that the temperature of the water applied to the roots is about 70°. The pinching of the shoots will require careful attention, and remove fruits whenever they are of a usable size.

SPINACH AND SPINACH BEET.

If this crop was not sown too late in the year there will be good growth on the plants. In gathering this crop the largest leaves only should be picked, and care should be taken not to denude the plants too severely. In dry weather the soil should be stirred frequently. Early in the year a slight dressing of bone-meal or some good fertiliser should be given and hoed in. Where this vegetable is in much demand Spinach Beet should also be grown, as it does well in cold, damp gardens where the Priekly Spinach often fails to stand the winter. The leaves may be gathered and used separately or mixed together with the Spinach proper.

CARROTS AND TURNIPS.

Where early crops of these are grown, and without the aid of hot-water apparatus, it will be necessary to make preparations for the making of hot-beds. The fermenting material should be thrown into a large heap and turned several times before building. The soil for Carrots should be of a light sandy nature, mixed with some soot and wood ashes. The surface of the bed should be raised to within 12 inches of the glass. When the soil has been warmed throughout the seeds may be sown either in rows or broadcast. The best variety for this work is Sutton's Foreing, and a good Turnip is Early Milan.

SEEDS.

The seed catalogues are now arriving, and before ordering all the old seeds should be tested. Count a certain number of seeds and sow in small pots, placing them in a brisk heat. Should they show weak germinating power they should be discarded. Clean out the store-room, and have everything ready for a new supply.

THOMAS HAY.

Hoptoun House Gardens, South Queensferry.

ORCHIDS.

ODONTOGLOSSUM URO-SKINNERI.

THANKS to recent importations this beautiful Orchid is more plentiful; it is well worth growing in quantity. The new growths are sufficiently forward now to allow repotting being done in a mixture of two parts each of fibrous peat and chopped sphagnum and one part leaf-soil well mixed with a little coarse sand and some small crocks. Pots should be the receptacles used, half filling them with chopped rhizomes. The potting should be done very lightly, so that the thick, fleshy roots may easily enter the compost. I like top-dressing with chopped sphagnum; then, if the surface moss is kept humid to encourage its growth, an occasional watering about every three weeks will be ample till the new pseudo-bulb shows signs of swelling. A position in the coolest part of the intermediate or the warmest end of the cool house is suitable.

MASDEVALLA TOVARENSIS.

This beautiful albino, that will soon be commencing to flower, is frequently very troublesome at this season, by reason of its leaves suddenly damping off. This to a large extent may be avoided by placing the plants in a light house such as the coolest end of the intermediate house, and afford water only when the material in which they are grown is dry. If the house in which they are at this season is continually damp, the leaves will probably fall off, so the first point is to see that the house is well ventilated.

HYBRID ORCHIDS.

With the introduction of so many lovely sorts, especially of *Lælias* and *Cattleyas*, it is possible to have Orchids in flower all the year. Many of them have no proper flowering time like the old species. Some rest, some flower, and some grow at the same season, so the grower must treat each plant accordingly. The parents should also be known, so that at least to some degree the treatment necessary for them may be partially meted out to the hybrid. Especially is this necessary in those derived from *Lælia cinnabarina* and *Brassavola digbyana* crossed with other *Lælias* and *Cattleyas*. The hybrids require to be kept fairly on the dry side except when they are growing and rooting freely. Hybrids, taking them generally, are of more easy culture than species, and, now that many may be obtained at reasonable prices, I would advise all growers of Orchids to start the new year by adding some to their collections. To those wishing to raise seedlings I may say this is one of the most fascinating parts of Orchid growing. Some of the finest hybrids from which to obtain pollen must be grown, otherwise the hybridist will find when his seedlings flower that he is only where others were years before. In this age of progress it should be the aim of all Orchid growers to improve their plants as years go by.

HARDINESS OF ROMNEYA COULTERI AND OSTROWSKIA MAGNIFICA.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I notice that in Chapter VII. of "Colour in the Border" the writer refrains from recommending the above plants on account of their tenderness. I am perfectly in accord with her that they are not plants to be included in the general list for the ordinary herbaceous border, for both often prove extremely difficult to manage. I, however, doubt their failure being due to tenderness. As reference to former volumes of THE GARDEN will show, *Romneya Coulteri* has proved hardy in the open in Scotland, in North Wales, in the neighbourhood of Leeds, and in other comparatively cold districts, while *Ostrowskia magnifica* flourishes in Northamptonshire, where it attains the height of about 7 feet, and we are told that it succeeds in New York State, which has the disadvantage of a winter climate far colder than our own. In the article accompanying the coloured plate of *Ostrowskia magnifica* (THE GARDEN, Vol. XXXIV., page 604) it is stated to be "capable of withstanding the most severe cold of our climate," as, indeed, it ought to be, seeing that it is a native of the higher mountains of Eastern Bokhara. Even in the south-west both these plants, in some instances, defy successful culture, although every care is taken for their well-being. In a garden in the neighbourhood of Penzance, where Australian shrubs thrive to perfection, *Romneya Coulteri*, though tried again and again, absolutely refuses to become established, and in several gardens that I am acquainted with *Ostrowskia magnifica* has proved a complete disappointment. However, both are such exceptionally lovely flowers that they are well worth a trial. It is difficult to say which is

the most beautiful, the Romneya with its wide-spread, pure white, crepe-like blossoms, with their central boss of gold, and delicate fragrance, or the great Bellflower, with its satin-petalled cups, lavender or white, fully 6 inches across. The last-named flowers last marvellously in water, blossoms out this year when partially expanded retaining their beauty indoors for fully a fortnight. I am unable to indicate any royal road to success in the case of the Romneya, though it, happily, does well with me, but I believe a great point with the Ostrowskia is to protect the roots from excessive moisture during the plant's long period of rest by a hand-light or frame. S. W. FITZHERBERT.

YELLOW-FLESHED AND ASHLEAF POTATOES TO EAT.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—The grateful thanks of those who are not heavily struck with the Potato "disease" is due to the Rev. G. H. Engleheart for the brave stand he makes—and at such a time—in favour of yellow-fleshed Potatoes in general and Ashleaf varieties in particular. No variety I am acquainted with possesses such a decided Potato flavour as Myatt's Ashleaf, except the black Potato Congo, and for obvious reasons it will never be largely grown. So superior do we find Myatt's to the general run of Potatoes that now I grow none but this—forced or natural—for my employer's table. J. R.

ROSE FELICITE PERPETUE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In a little handbook recently issued by a committee of the National Rose Society, under the title of "Hints on Planting Roses," which is full of most useful hints to beginners in Rose-growing, not the least useful feature is a list of sixty best Roses for garden decoration, and I am delighted to find that the beautiful climbing Rose *Félicité Perpétue* ranks as the best of the summer-flowering White Ramblers, and this it undoubtedly is. The accompanying photograph shows what an excellent variety it is for rustic arches and pergolas. The plants photographed have been planted only four years, and both last year and this the arch has been a veritable picture during June and July. The illustration suggests the question. Why are our churchyards so often planted with sombre evergreens with nothing bright in the way of Roses and flowering shrubs to relieve them? Surely, no place can be more appropriate than "God's acre" for the many beautiful flowering plants now in cultivation.

Cirencester.

E. A. JEFFERIES.

MISCELLANEOUS.

CULTIVATION OF CACTI.

(In reply to L. Vrenod.)

IN the first place, then, the name Cactus is popularly applied to all the varying genera in the extensive natural order Cactaceæ, which embraces *Opuntia*, *Cereus*, *Mammillaria*, *Echinopsis*, *Echinocactus*, *Phyllocactus*, *Melocactus*, *Epiphyllum*, and many more. In *Epiphyllum*, *Opuntia*, *Phyllocactus*, &c., the plants are composed of fleshy flattened branches or stems. In *Mammillaria*, *Echinopsis*, *Echinocactus*, &c., a totally distinct growth is seen. *Mammillaria* has a nearly ball-like outline, the plants appearing in groups. This genus is a most extensive one, and in its entirety may safely be regarded unique by reason of the remarkable symmetry of outline and the spirally disposed nipple-like tubercles that crowd and cover the exterior of the plant. The flowers are generally small and sometimes insignificant, but the plants are worth growing for their beauty of form alone. In *Echinopsis* the plant is globular or sub-globular or cylindrical, and arranged on the ridge and furrow plan, the ridge or ribs being protected with bunches of sharp spines. The flowers of this group are of extreme beauty and delicacy, 6 inches to 8 inches long in some kinds, sepals

numerous. The flowers are very fragrant, and vary from funnel shape to trumpet shape. An interesting characteristic is that the stamens are arranged in two series, the one set usually flat and adherent to the tube, the other set free and moving with the least touch. These plants prefer a warmer position than most kinds. The *Echinocactus* may briefly be said to be a modified form of the last, with, in some species, the spiral arrangement of the *Mammillaria* externally. This will give you some idea of the best known genera, the species of which are found from Texas and California to Peru and Brazil, though, doubtless, most abundant in Mexico. The majority may be well grown in a rather dry arid temperature of 45° to 50° in winter, during which season little moisture should be applied to the roots. With the warmer conditions of summer and the appearance of new growth more water may be given. In this connexion it is worth remarking by reason of the external structure of many kinds—the ridge and furrow of the *Echinopsis* for example—forming a conduit to the roots, that no haphazard watering overhead or indiscriminate syringing should be indulged in, for the plants of nearly all genera are very sparse rooting, and therefore unable to utilise free supplies of moisture.

The potting is best done in May and June, many kinds, however, are best for several years without disturbance. The finest potting compost is of strong loam with silver sand, old mortar, and soft brick, broken up finely in about equal parts. The drainage, independently of the open nature of this soil mixture, should be always abundant. Potting

ROSE FELICITE PERPETUE IN CHURCHYARD.

should be firmly done. In case of basal decay the best plan is to shake the affected plant free of soil and, securing some powder dry silver sand, place the plant in a shallow box on a shelf near the glass in full sun for a time. An interesting item just now is the grafting of some kinds, the *Epiphyllums* on the *Pereskia* for example, the stocks being first well established. As you are interested in these plants you should obtain Mr. Lewis Castle's book on "Cactaceous Plants." E. J.

SOCIETIES.

NATIONAL DAHLIA SOCIETY.

REPORT FOR 1904.

THE past season, though less generally unfavourable than its predecessor, was in many respects a trying one for Dahlia growers. During the whole of the three summer months an absolute drought prevailed in most districts, and the early autumn was marked by successive cold snaps, which brought the season for first-class blooms to an unusually early close.

The annual exhibition was held on September 2 and 3, at the Crystal Palace. The number of exhibits was below the average, but the quality of the blooms staged was distinctly above it, most noticeable being the marked advance in the amateur section in form and method of staging.

On September 20, a meeting of the committee was held at the new Horticultural Hall, Vincent Square, on the occasion of the fortnightly show of the Royal Horticultural Society. Ten certificates were awarded to new varieties. The number of certificates awarded to new varieties in 1903 was nineteen, and in the present year twenty-one, out of a total of 125 seedlings exhibited.

The committee desire to convey their best thanks to the donors of special prizes; also to the Horticultural Club for kindly allowing the society's meetings to be held in their club room.

The amount offered in prize money at the 1904 exhibition was £106 10s., compared with £85 15s. in 1903, and the committee have decided to further increase this to £123 5s. in 1905. They would point out, however, that the present increase is only enabled to be made owing to economies in expenditure under various heads, and it is not due to an increasing revenue from members' subscriptions. Eighteen new members have joined during the year (which gain has been practically neutralised by resignations), and in only one case was the new comer introduced by an existing member. The committee would impress upon members that the future prosperity of the society must depend on individual efforts being made to obtain recruits, and would suggest that neighbouring Dahlia growers might often be approached with success if the advantages of membership, in return for an annual payment of five shillings, were put before them. The committee desire to express their thanks to Mr. C. Harman Payne for kindly allowing his "Bibliography of the Dahlia" to appear in the "Official Catalogue and Culture Guide," and regret that the acknowledgment was omitted in the publication itself. The income of the society from all sources, including the credit balance of £17 9s. 5d. from the year 1903, amounted to £189 3s. 5d., and the entire expenditure, including the payment of all prizes awarded at the annual exhibition, amounted to £166 3s. 11d., leaving a balance in the treasurer's hands of £23 4s. 6d. The annual exhibition will be held at the Crystal Palace on Thursday and Friday, September 7 and 8.

A meeting will be held at the new Horticultural Hall, Vincent Square, on September 26, for the purpose of awarding certificates to seedling Dahlias. Entries will be received by the hon. secretary at the Horticultural Hall before 11.30 a.m. on the morning of the show. "Fellows" of the National Dahlia Society are entitled to four passes, admitting to the society's grand exhibition at the Crystal Palace on September 7 and 8; "associates" to two passes; and "ordinary members" to one pass. Each fellow, associate, or ordinary member, on joining the society, will receive a copy of the "Official Catalogue and Culture Guide of the National Dahlia Society." Fellows, associates, and ordinary members alone have the privilege of exhibiting at the exhibitions of the National Dahlia Society.

ST. IVES SHOW, HUNTS.

ON Monday, the 19th inst., the above show was held in a large tent adjoining the Cattle Market, and proved to be a most interesting and successful exhibition. This was largely due to the splendid energy and untiring exertions of the honorary treasurer, Mr. R. Copley, who, with the secretary, Mr. G. H. Cannon, and the committee, are to be warmly congratulated upon making this show so successful as it annually is. The show consists of farm and dairy produce, roots, vegetables, and fruits, and in all sixty-six classes were provided. In nearly every case the prizes were keenly contested, and it was a real pleasure to see so much interest taken. Agricultural roots were exhibited in large numbers, and very fine specimens of the different types were on view; particularly noticeable were the Kohl Rabi, as many as sixteen competing in a single class for six specimens. Potatoes, both round and kidney, were well shown in nearly every case, the tubers being of medium size and beautifully clean. For twelve round, Mr. H. Goodman, St. Ives, was a splendid first, Mr. F. T. Beeton, Ramsay Hollow, being second. For twelve kidney, Mr. R. Stevens, Gaynes Hall Gardens, secured the first; Mr. T. Lockie, Diddington, second. Some fine bulbs were exhibited in the class for twelve Onions, and that veteran grower Mr. T. Lockie was well first with exceptionally good and well-kept specimens; Mr. R. Stevens, second, with equally well ripened but smaller bulbs. In a class for six long and six short horn Carrots several fine lots, for so late in the season, were staged, Mr. J. W. Laud, Bluntisham, securing first, and Mr. J. Armon, Fentonston, second. The fruit competition was remarkably keen, as many as thirty-three showing in the class for five dessert Apples, excluding Cox's Orange Pippin. Mr. W. Hinson, St. Ives, secured the premier award here, closely followed by Mr. J. W. Laud. Twenty dishes of fine cooking Apples were staged, Mrs. Morgan, Fentonston, being first with remarkable specimens of Lord Derby. In a class for five Cox's Orange Pippin twenty-three lots were set up, Sir A. W. Marshall, Buckden Towers, being a splendid first; second, Mr. J. Linton, Stirtloe; third, Mr. C. Consins, Diddington. Mr. F. W. Seabrook was first for three varieties of cooking Apples, and Mr. H. Gilliat, Abbot's Ripton Hall, for three varieties of dessert Apples. The competition for dessert Pears was nearly as largely contested, and many well kept dishes were shown, especially of that splendid variety *Josephine de Malines*.

NATIONAL AURICULA AND PRIMULA.

THE annual general meeting of this society took place at the Hotel Windsor on the 17th inst., when there was a good attendance of members. The twenty-eighth annual report set forth that there had been a slight diminution in the members during the past year, and an appeal is made to members to strengthen the society by bringing in new members. There was also a corresponding falling off in the amount of subscriptions for the past year. Still, the committee are able to carry forward a balance. The exhibition which took place on April 19 last was in every way a decided success, and reflected the greatest credit upon the exhibitors. One satisfactory feature was the fine quality of the flowers exhibited by new members. The best thanks of the society were given to Mr. J. Douglas for generously presenting four medals for competition, also for his kindness in distributing choice seeds of alpine Auriculas to the members, a gift which is greatly appreciated by them. Thanks were also given to Mr. W. Smith of Bishop's Stortford for the encouragement he gives to new exhibitors by providing the prizes in three classes specially set apart for such. The support given to the society by the Royal Horticultural Society in granting a donation to the funds of the society, and for the arrangements made to facilitate the staging of the flowers, is also acknowledged, as also the kindness of the committee of the Horticultural Club for the use of their room for the annual and committee meetings.

The treasurer's statement shows an income of £72 16s. 8d. for the year, including the balance in hand; the expenditure was £71 16s. 8d., including £55 17s. 6d. awarded in prizes, a larger sum than in 1903.

The president, vice-presidents, and committee were re-elected, and the name of Mr. W. Bathgate-Cranfield was added. The auditors and honorary secretary and treasurer (Mr. T. E. Henwood) were also re-elected. The schedule of prizes underwent some revision, and it was announced that Mr. W. B. Cranfield would give the first prize of one guinea in the class for four show Auriculas, dissimilar, and Mr. P. Riddell the same sum as a first prize in the class for six alpine Auriculas, dissimilar. Miss Willmott also continues her special prizes of one guinea, and Mr. James Douglas his gift of the Royal Horticultural Society's medals.

The annual exhibition is fixed to take place in the exhibition hall of the Royal Horticultural Society, Vincent Square, on Tuesday, April 25, the council contributing the sum of £10 to the prize list as heretofore. Mr. T. E. Henwood was heartily thanked for his services as honorary treasurer and secretary.

CARDIFF GARDENERS' ASSOCIATION.

The Cardiff Gardeners and friends met at the Sandringham Hotel on Wednesday, the 7th inst., and entertained Mr. John Basham and Son to a dinner given in their honour as an appreciative recognition of the many kindnesses extended to the Gardeners and friends by Mr. and Mrs. Basham and family, and particularly the hospitality shown on the occasions of the two enjoyable outings to Bassaleg, 1903-4. Mr. E. H. Battram, F.R.H.S., presided over a large and representative gathering. After an excellent dinner served by Mr. Smith (the host), the toast "The King and Royal Family" was given by the chairman, with musical honours. The next toast was that "Our Guests," proposed by the chairman and received with unbounded enthusiasm, so popular is this veteran pomologist in Cardiff. Mr. Basham, sen., in reply, said he desired to thank the Gardeners on behalf of himself, Mrs. Basham, and family, for the unexpected kindness to them that evening, and, giving a brief history of his life and much valuable advice to the meeting in general, concluded by saying that as long as the name of Basham and Bassaleg went together those present at the dinner would be ever welcome. "The Visitors" were next proposed by Mr. T. Clarke, and responded to by Mr. Fletcher. "The Gardeners" was proposed by Mr. J. Marsh, and responded to by Mr. T. Clarke, who said the gathering was the largest that had been brought together for at least ten years. Mr. Fletcher proposed the hon. sec. (John Julian), who had charge of the arrangements. Messrs. Hodge, Parsons, and Jones supplied the vocal and instrumental part of the proceedings. The hon. sec. proposing a vote of thanks to the chairman brought the proceedings to a close.

A meeting was held at the Sandringham Hotel on Tuesday, the 13th inst., when Mr. T. Clarke presided. An excellent lecture was delivered by Mr. C. Orchard (representative of the Bristol Gardeners' Association) on "Greenhouse Climbers," embracing the majority of the most useful kinds for decorative purposes, and dealing with the cultivation and general treatment. A good many useful hints were given during the discussion. The best thanks of the association were accorded Mr. Orchard, who briefly thanked the members.—J. JULIAN.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening maybe, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 5, Southampton Street, Strand, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

Bulbs and tubers (W. J. SHARP).—Tuberous Begonias that were lifted at the end of October, and after having been allowed to get partially dried, were placed closely together in shallow boxes of moderately dry Cocoanut fibre, now require to be overhauled for the purpose of removing any that may be decayed, and giving the sound tubers a fresh supply of damp fibre to keep them plump till it is time to start them into growth in frames. Gladioli roots cannot well be kept too dry, but the place where they are stored should be cool to prevent them starting into premature growth. Our roots are laid thinly on the shelves of a dry fruit room, together with a quantity of Liliums that are closely packed in slightly moist soil. Anemones and Ranunculuses have wintered well on the same shelves, and these have now been put ready for planting as soon as the ground is sufficiently dry to ensure the work being done well.

Early Radishes (FOREMAN).—Quickly grown early Radishes are the most digestible, and, in addition, form a very attractive dish on the breakfast table. They may be either grown with the earliest Carrots, or, better still, in a frame separately. In the former case, the drills should be drawn midway between those intended for Carrots, the seed being sown thinly so as to necessitate but little thinning out. It germinates very quickly, and the frames must therefore be uncovered before the Carrots are visible, or the Radishes

will be unduly drawn. Not much air is needed, but all the light possible should be admitted. If the seedlings are crowded they will fail to bulb quickly, and perhaps not at all; they ought therefore to be thinned out early, leaving them from 2 inches to 3 inches apart. When a frame is given wholly up to them, this may be prepared similarly to that intended for Carrots, and the drills formed 6 inches apart, the seed being sown thinly, and the bed duly smothered over.

Diseased Rose wood (WORKSOP).—The sample of Rose wood sent shows that the bark is badly infected with a fungus similar to that seen on cankered fruit trees. No doubt it is attributable to the same cause which promotes canker on fruit trees. The roots have got into some deep poor or sour soil, and because of that the wood is immature and the bark susceptible to disease. We should advise, if it is possible, that you lift your Rose tree from its present soil, that you moderately prune the roots, then replant it, keeping the roots laid out more shallow and level, burying them about 6 inches deep. But before doing that cast the top soil on to one side, then throw out and wheel away some 6 inches of the bottom soil and replace it with as good fresh soil as you can. Place some specially good fine soil, including decayed leaf-soil, old hot-bed manure, and sharp sand about the roots before covering up with the ordinary soil. Tread it gently to settle it well down, then place over the whole a light layer of long stable manure to help protect the roots from sharp frosts during the winter. A few weeks later, after the soil is well settled, prune the tree very hard, cutting off fully one-half its wood and having it burned. Then make up a solution of 1oz. of soda and 1oz. of commercial potash dissolved in a quart of boiling water. To that add 2oz. of soft soap and a little clay to make it as thick as paint. Then with a brush thoroughly coat all the bark of each stem or shoot over and leave it. It will be well, however, to leave the prospective buds untouched. That treatment should result in a complete cure. When these fungoid diseases get hold of trees, Roses, or other things only drastic treatment will act as real cures.

Retarding Roses (M. V. K.).—We take it that you desire your Roses to blossom the latter part of June and through July. There are three methods whereby this could be accomplished, viz., by late pruning, by transplanting, or by removing flower-buds in May. If your Roses consist mainly of Hybrid Perpetuals we should advise late pruning. Instead of pruning in March leave the operation until the middle of April. You could paint the cut ends of the shoots with grafting wax or painter's knotting to prevent the loss of sap. The second method, namely, transplanting to spring, has much to commend it. This could only be successfully carried out with plants that had been transplanted not more than three years ago. We have often adopted this plan in order to prolong the blossoming of our Rose garden. Thirdly, removing the buds early in May is a plan often resorted to. We have found frequently, when Rose shoots have been partially injured by spring frosts, that the cutting back has caused the plants to blossom much later. We should advise this plan mostly as regards Tea Roses, and the first named plan with the Hybrid Perpetuals. With the single-flowered and ordinary so-called garden Roses late pruning would be the best practice to adopt, but so much depends upon the season. If you could allot a piece of ground each year for planting out some Briars and Manetti stocks, and if these were budded with Hybrid Perpetuals and Hybrid Teas you would have plenty of fine quality blossom all through July. These yearling plants are always later in flowering than are the established plants.

Vine scale (T. W.).—Judging by the portion of wood and leaf sent your Vines are more badly affected with white scale (*Coccus vitis*) than any Vines we have yet seen. So bad is your case that only the most drastic remedies will meet it. First pull off every leaf and carefully place them into baskets, then burn them. Next prune the Vines very hard indeed all over, remove and burn every portion. Next remove from the main stems, or rods, all loose stringy bark. Cleanse with strong soapy soda hot water all glass and wood. Wash the brickwork with hot soda water, then coat with fresh hot lime-white as hot as can be applied. Next get 4oz. of soda and 4oz. of common potash or pearl ash, dissolve both in boiling water 2 quarts each. Add to that 1lb. of soft soap, mix with dry clay, half a pint of paraffin, and add that to the other, so that a thick paste results. Then paint over every portion of the stems, thoroughly coating them, but spare the base-buds left to break next year. These may be washed with warm water only, lest the mixture coat and check growth. Let that solution remain until it naturally peels off. That would kill or suffocate the scale. It will also be well finally to carefully remove 3 inches of the soil on the border, if it be inside, and replace it with quite fresh soil. If your vine is heated by hot-water pipes it may help to keep the insect in check next summer, if you make up a wash of sulphur and soap, and coat your pipes with it once a month, making the pipes hot now and then at night when the house is closed. No ordinary remedy will check the insect you are troubled with. Many would root out their Vines and burn them, cleanse and paint the house, and plant new Vines.

Flower garden (J. H. STRABER).—There are quite a number of ways in which the garden may be treated with good results. Those more or less formal would suit we think by reason of its size and general character, so far as these can be rightly ascertained by the plan you submit. What would prove the most suitable would of necessity largely depend upon environment, while your own tastes and desires would naturally have to be consulted. Retaining for the moment somewhat of the character of the central portion, we would discard the 8 feet wide herbaceous borders at the southern side and throw these into the larger space for treatment generally as a grass plot. The central part from east to west may be in one plot, or as now intersected by a path of some kind. The narrow border on the north side would also come into the same area. Assuming that greater floral effect is the aim at present, we will admit this central portion to be in two equal parts. At each of the corners this produced a bed could be formed, having its approxi-

mate centre at the corner point, and, while extending in parallel line to each direction—i.e., north, south, east, and west—open to the lawn with an informal outline. These beds may contain climbing Roses on rustic poles, and be filled otherwise with choice bulbs, such as Daffodils, Irises, Lilies, Gladioli, Muscaris, Chionodoxa, &c., with Peonies, Alstroemeria, Flag Irises, and Iris species in great variety, Pyrethrums, Sunflowers, and many more. In the plants named there is a great wealth of material and variety also. Between the points of these beds a bed of different form could be placed. In these could be massed bulbs for spring, Glove Carnations for summer, and Gladioli for autumn. With the Daffodils deeply planted these could occupy any one bed, while Daffodils and tuberous Begonias could occupy another, and so forth. A large centre bed in each plot could be made gay either with permanent subjects or annual bedding things. Shrubs, flowering and otherwise, would find a place. Over the flagged pathway a good pergola could be made, and this alone would create quite a feature when clothed with Clematises, Roses, Wistaria, and other things. A pergola may also be placed on the opposite side. The same area could also be laid out more freely into beds, the corners rendered into rocky beds, from which a large array of choice bulbs, alpine, and the like could be seen to advantage, and if desired water plants could be introduced. The shrubbery at the house end could be made very effective with Hollies, among which, some of the best Lilies and Erenurus—the latter with towering spikes of white or pink flowers—could be permanently planted. Beds of hybrid Tea and other Roses, carpeted with spring bulbs or tufted Pansies, could also be arranged, once the chief central or governing part was decided upon. Adopting a different view entirely, the central part could be devoted to spring and summer gardening, that is to say, the annual effective bedding of bulbs in spring, and masses of other things for the remainder—Begonias, Ivy Pelargoniums, and the like, beds of Cannas, or of select Dahlias appearing at the extreme end from house. With such an arrangement a fountain basin may occupy the centre of the lawn, with choice Water Lilies therein. If this idea were favoured, much could be made of the remainder by grouping shrubs, Lilies, Peonies, Delphiniums, and a host of other choice and good things, as Carnations, Pyrethrums, Phloxes, &c., not to solitary plants, but in fine masses that catch the eye and that make the garden a pleasure and a delight. The dry wall facing croquet ground should also be capable of treatment, and many things could be planted that would be very beautiful when in flower, and decidedly more pleasing than bare masonry at any season. If it is likely we can further assist you, please write us again, as it is our desire to help our readers as much as possible.

Mocassin Flower (CYPRIPEDIUM SPECTABILE).—This beautiful species is so hardy that we doubt if any frost experienced in this country or Holland would have the least effect upon the plant. Being a deciduous kind, that is dying down each year and forming buds quite below the surface of the soil, it is better able to endure frost and cold than if the plant did not die down. If, however, you have any doubt in the matter you may cover the crowns with fine peat, leaves, or even short, dry litter from the manure heap. Either of these would form a quite adequate covering for its protection and safety. In our ordinary winters in England little snow covers the ground, but we have known the plant frozen for weeks in succession without covering, and with the crown-buds of the plant quite near the surface, without being injured in the least. As a precautionary step, however, when the plants have been in a bog-bed, artificially supplied with water, we take off the supply of water from November to February inclusive. In the natural tufts the flowering crowns are always buried deeply in the close vegetable matter that abounds, and this obvious lesson should be kept in mind when planting it artificially.

Chrysanthemums on single stems, to flower on the break bud (R. K.).—It has been our pleasure to reply to your interesting questions on former occasions, and the present is no exception to the rule. We gather that you wish us to name varieties that open the break bud satisfactorily, and give a good flower as the result. You also appear to have a preference for Chrysanthemums of the Japanese incurved type, and we are interested to learn that in St. Petersburg these blooms keep better than those of looser build. Large and handsome flowers of white, mauve, pink, and rosy pink colours are desired, we understand, and on this account we will confine our selection to those of the colours named. Your experience with varieties Princess Alice de Monaco, Mrs. J. C. Neville, Chas. Longley, and Mme. Paolo Radelli we are glad to know has been one of success, and those in the subjoined list we have every reason to believe will be equally good: Australe, rosy amaranth inside petals, with silvery reverse, tall; Western King, purest white; Mrs. S. C. Probin, clear pink, with silvery reverse; Mrs. Barkley, rosy mauve; W. Duckham, pale mauve, a very large and handsome flower; Miss Alice Byron, pure white, very chaste; Mme. Louis Remy, pure white sport from Mrs. C. Harman Payson; Mme. Philippe Rivore, pure white, rather late; Mme. Gabrielle Derbrie, Malmesbury-pink; Mrs. J. Dunn, a large deeply-bellied reflexed Japanese flower, white, splendid quality; Renee, lilac-mauve, large full flower; Mrs. C. Beckett, pure white, reflexed Japanese; Lady Conyers, a full flower of a rosy pink colour; Lady Hopetoun, a very large flower, colour heliotrope-pink; Mme. Herreweghe, a pure white sport from Australe; Miss Lucy Evans, a lovely shade of heliotrope-pink; Mrs. E. Hummel, pinky white, shaded yellow, very large flower; Mrs. Geo. Milham, bright rose-pink, excellent; Souvenir de Pere Calvat, white, tinted rose and yellow; and Seagull, massive flower, white.

GARDENING APPOINTMENT.

MR. PEACE has been appointed head gardener to C. E. Sandford, Esq., St. Minver House, Wadebridge, North Cornwall.
